

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<u>http://bmjopen.bmj.com</u>).

If you have any questions on BMJ Open's open peer review process please email <u>info.bmjopen@bmj.com</u>

BMJ Open

Association of serum uric acid with all-cause and cardiovascular mortality in peritoneal dialysis patients: a systematic review and meta-analysis of observational studies

	1
Journal:	BMJ Open

31 Abstract

Objectives To analyze association of serum uric acid (SUA) with all-cause and
 cardiovascular (CV) mortality in peritoneal dialysis (PD) patients to inform clinical
 practice and further research.

35 **Design** A systematic review of observational studies.

36 Data sources We searched PubMed, Embase, Web of Science, the Cochrane Library,

37 CNKI, SinoMed, VIP and Wan Fang electronic databases from their inception to

38 January 2021. We included cohort studies and case-control studies reporting SUA and

39 mortality in PD patients.

40 Methods Effect estimates were presented as hazard ratio (HR) with 95% confidence

- 41 interval (CI) in meta-analysis using STATA 16.0, and synthesized studies qualitatively
- 42 when data not suitable for pooling analysis.
- 43 **Results** Fourteen cohort studies with 24031 patients involved were finally included. No
- 44 case-control study was identified. In prospective cohort study, pooled result of highest

45	SUA category was significantly higher than lowest for all-cause (1 study; 1287
46	participants; HR 1.79; 95%CI 1.17-2.75) and CV mortality (1 study; 1287 participants;
47	HR 2.63; 95%CI 1.62-4.27). And an increase of 1mg/dl in SUA level was associated
48	with an 16% increased risk of all-cause mortality (1 study; 1287 participants; HR 1.16;
49	95%CI 1.03-1.32) and 34% increased CV mortality risk (1 study; 1287 participants;
50	HR 1.34; 95%CI 1.16-1.55). While, in retrospective cohort studies, highest SUA
51	category was not found to elevate all-cause (5 studies; 4570 participants; HR 1.09;
52	95%CI 0.70-1.70) and CV mortality (3 studies; 3748 participants; HR 1.00; 95%CI
53	0.44-2.31) compared with lowest. And there was also no increase in all-cause (8 studies;
54	11541 participants; HR 0.94; 95%CI 0.88-1.02) and CV mortality (3 studies; 7427
55	participants; HR 0.90; 95%CI 0.76-1.06) with every 1mg/dl increase in SUA level.
56	Conclusions Results of prospective cohort study and retrospective cohort studies were
57	inconsistent. Consequently, prospective, multicenter, long term follow-up studies are
58	required in future to confirm association of SUA and mortality in PD patients.
59	Trial registration number International Platform of Registered Systematic Review and
60	Meta-analysis Protocols (INPLASY.COM) registration number:202140020.
61	Strengths and limitations of this study
62	This is the first systematic review of observational studies exploring the correlation
63	between SUA level and mortality in PD patients.
64	We used critical systematic review and subgroup analysis to describe the results and

64 We used critical systematic review and subgroup analysis to describe the results, and65 proposed future research direction.

66 In spite of many important confounding factors had been adjusted in the studies,

Page 5 of 40

BMJ Open

residual and unknown confounding still can not be excluded entirely.
Part of necessary data in the studies was not obtained, exploration of dose-response
relationship failed, it needs to be further determined in future.

70 Introduction

End-stage renal disease (ESRD) is one of the major diseases affecting human health, which causes enormous pressure and burden on medical care and society. Peritoneal dialysis (PD), as one of the effective alternative treatments for ESRD, has many features, such as stable hemodynamics, protection of residual renal function (RRF), good removal of middle molecular toxins, low risk of infectious disease infection, health economics advantage and home treatment [1]. Currently, PD has been widely used all over the world. Epidemiological survey results showed that as of 2013, the total number of people receiving peritoneal dialysis worldwide reached approximately 220,000 [2]. Of concern, patients with ESRD treated with dialysis still have a high mortality rate [3]. Therefore, the identification of potential risk factors that can be intervened is still an important topic in the field of PD, which is of great significance for improving the prognosis of patients and increasing the quality of life.

Uric acid (UA) is the final product of purine nucleotide metabolism in humans. Previous studies have demonstrated that elevated serum uric acid (SUA) was closely related to the increased risk of hypertension, peripheral arterial disease, cardiovascular (CV) event and chronic kidney disease (CKD) in general population [4-7]. And higher SUA level also appeared to be an independent risk factor for all-cause and CV mortality in CKD subjects [8,9]. However, there were conflicting results about the relationship

between SUA level and risk of death among dialysis patients. For hemodialysis population, many studies have confirmed that hypouricemia significantly increased the mortality of maintenance hemodialysis patients [10-12]. Nevertheless, SUA's role for all-cause and CV mortality in PD patients has been controversial. One study in PD patients indicated that elevated SUA level was an independent risk factor for all-cause and CV mortality in men treated with PD [13]. The result of another study showed that the prognostic value of SUA in all-cause and CV mortality was weak in PD patients [14]. Whereas hyperuricemia was found to predict lower risk of all-cause mortality in PD patients with lower relative appendicular skeletal muscle in another study [15]. In short, results regarding the effect of SUA on the prognosis of PD patients appeared to be inconsistent.

At present, there is a lack of systematic reviews on the relationship between SUA, all-cause and CV mortality in PD population. We hypothesized that there may be exist independent correlation between elevated SUA level and mortality in participants with PD. Thus, we systematically analyze available studies to determine whether the hypothesis was right.

105 Methods

Protocol and registration

Methods of this review were specified in advance and documented in International
Platform of Registered Systematic Review and Meta-analysis Protocols
(INPLASY.COM). (Registration number:202140020). The content of this review
was reported according to the guidelines of "Meta-analysis of Observational Studies in

(1) Hazard ratio (HR) and its corresponding 95% confidence interval (CI) (or other data 133 to calculate them) of all-cause or CV mortality for 1mg/dl change in SUA level, or for 134 the highest versus lowest SUA category or the lowest versus highest category could not 135 be obtained from the original article; (2) Cohort studies with a total sample size of less 136 than 100 participants; (3) If studies originated from the same series of cohort samples, 137 or part of the cohort samples were published repeatedly, only the literature with the 138 largest sample size and the longest follow-up could be included, and the rest of the 139 literature need to be excluded. 140

141 Search strategy

Two authors (X.X. and H.C.) searched the following Chinese and English databases 142 from their inception to 15th January 2021. Chinese databases included China National 143 144 Knowledge Infrastructure (CNKI), SinoMed, Chinese Science and Technology Journal Database (VIP), and Wan Fang Database. English databases included PubMed, 145 EMBASE, the Cochrane Library, and Web of Science. Trial registers including Clinical 146 Trials. gov and the World Health Organization International Clinical Trials Registry 147 Platform were also searched. Additionally, related reviews, conference papers, 148 references lists and gray literatures also were searched manually to minimize the 149 missed detection rate. No language or publication type was imposed, published 150 abstracts were also considered. If there was a lack of information in the retrieved 151 literature, it was necessary to contact the author via email to obtain the missing data to 152 ensure that literatures could be included in a comprehensive way. Taking "PubMed" as 153 an example, the retrieval strategy was as follows: ("Uric Acid" [Mesh] OR "Uric Acid" 154

OR "serum uric acid") AND ("Mortality" [Mesh] OR "Mortality") AND ("Peritoneal
Dialysis" [Mesh] OR "Peritoneal Dialysis" OR "PD" OR "continuous ambulatory PD"
OR "CAPD" OR "intermittent PD" OR "IPD" OR "automated PD" OR "APD" OR
"continuous cyclic PD" OR "CCPD" OR "tidal PD" OR "TPD").

159 Studies selection and data extraction

The titles and the abstracts were screened first, then the full-text versions were checked 160 according to inclusion and exclusion criteria. Two authors (X.X. and Q.L.) examined 161 the full text to identify the eligible trials independently. We made a data extraction 162 163 sheet in advance. Two authors (X.X. and H.C.) extracted data independently. Disagreements of studies selection and data extraction were resolved by consulting 164 corresponding author JP Liu. Information was extracted from each included trial on: 165 166 first author, publication year, age, gender, study design, dialysis duration, sample size, study location, center, length of follow up, categories according to serum uric acid, 167 comparison, adjustments, adjusted HR (95%CI). 168

169

60

Methodological quality assessment

The Newcastle-Ottawa Quality Assessment Scale (NOS) was used to assess the quality
of observational studies [17]. NOS allocated a maximum of 9 points for quality of
selection, comparability, and outcome of study population. Two authors (X.X. and J.Y.)
assessed and validated the quality of included studies independently. Any
disagreements were resolved by discussion with corresponding author JP Liu. Overall
study quality scores were defined as poor (0–3), fair (4–6), or good (7–9).

176 Statistical analysis

> SUA was analyzed not only as a categorical variable, but also as a continuous variable in the included studies. The statistical analysis for the overall association between SUA levels and death risk (all-cause and CV mortality) were based on random effects model and on comparisons of highest versus lowest category of SUA level, or by increase of 1mg/dl. HR and 95% CI were used as effect indicators. HR and corresponding 95% CI of each study were transformed to their natural logarithm (lnHR, lnlCI and lnUCI), and overall HR and its 95% CI was calculated by exponentiation of the pooled lnHR, lnlCI and lnUCI.

> If data of cases, person-years, and HR and 95% CI for each category were available in included studies, then a dose-response analysis would be performed to further explore the relationship between SUA and mortality. The potential non-linearity association was examined by modeling SUA levels using restricted cubic splines with three knots at 25, 50, and 75% of the distribution. We assigned the median or middle point of the upper and lower boundaries in each category as the corresponding dose to the related HR for each study. In case of P value > 0.05, the linear regression model should be considered.

> square (I^2) was applied to test the statistical heterogeneity among studies (Higgins and Thompson, 2003) [19]. When $I^2 > 85\%$, we believed that the results could not be poolled. Data not suitable for statistical pooling were synthesized qualitatively. To explore the source of heterogeneity among studies, subgroup analyses were conducted according to study design, study location, publication years, adjustment for sex, adjustment for DM and adjustment for albumin. Additionally, the meta-regression

BMJ Open

analysis was also performed to detect potential heterogeneity based on the above
variables when about 10 studies were included. Sensitivity analysis was performed with
removing one study at a time to explore the robustness of results if data were available.
The possibility of publication bias was detected by funnel plots and Egger's test if there
were about 10 studies. STATA16.0 software (StataCorp, College Station, Texas, 77845
USA) was used for data analysis.

205 Patient and Public Involvement statement

206 Patients or the public WERE NOT involved in the design, or conduct, or reporting, or

207 dissemination plans of our study.

208 Results

209 Search results

Two hundred and forty-two relevant citations were retrieved. After scanning the full texts, five literatures were excluded. We excluded cohort samples of the same series [13,15,20], only the studies with the largest sample size and the longest follow-up time were included [21,22]. Besides, we excluded a published abstract [23], due to its total sample size of entire cohort was only 60 participants. And another study was excluded due to whose pooled effect estimation were reported as odds ratio (OR) with 95% CI [24]. Finally, fourteen literatures were eligible for this review. Details of search and selection process were illustrated in Fig.1.

Characteristic of included trials

A total of fourteen literatures involving 24031 participants were included [14,21,22,2535]. The included studies were all cohort studies, including prospective and

retrospective studies. The main characteristics of included studies were demonstratedin Table 1.

223 Methodological quality of included studies

The overall quality of included studies was good with a mean NOS score of 7.57, with a range of 7–9. All studies receiving a NOS greater than or equal to 7 (eTable1 in the Supplement). Among them, in terms of "comparability", the most important confounding factors that need to be adjusted should include indicators of estimated glomerular filtration rate (eGFR) or serum creatinine (Scr) or urinary volume (UV) or residual renal function (RRF), which can reflect the patient's current residual renal function status. In addition, according to literature and clinical observations, other confounding factors that need to be adjusted should include gender, age, diabetes history, cardiovascular disease (CVD) history, Kt/v (urea clearance index, representing dialysis adequacy), use of UA-lowering drugs, and serum albumin (representing nutritional status).

Primary outcome

236 Association of serum uric acid in categories with all-cause mortality

In order to reduce the heterogeneity of methodology, we discussed the results respectively according to different study designs. In prospective cohort studies, summary HR and 95% CI of all-cause mortality for the highest SUA category compared with the lowest category came from one included study including 1287 patients [21]. As presented in Fig.2, pooled result of the highest SUA category was significantly higher than the lowest for all-cause mortality (HR 1.79; 95% CI 1.17-2.75).

In retrospective cohort studies, five studies with 4570 patients reported HR and 243 95% CI of all-cause mortality for the highest versus the lowest SUA category 244 [14,28,29,33,34]. The highest SUA category was not found to elevate all-cause 245 mortality (HR 1.09; 95% CI 0.70-1.70; Fig.2) compared with the lowest category of 246 PD patients. 247 HR and corresponding 95% CI were reported in three retrospective cohort studies 248 for the lowest versus the highest SUA category [26,27,31]. Among them, the data of 249 one of the articles [27] was supplemented by the corresponding author Changxiu via e-250 251 mail. The pooled HR was 1.52 (95%CI 0.79-2.89), with heterogeneity of I²=32.8%. Association of Serum uric acid per 1mg/dl increase with all-cause mortality 252 Only one prospective study with 1287 PD patients reported HR and 95% CI of all-253 254 cause mortality for 1mg/dl increase in SUA level [21]. And pooled result showed that for every 1mg/dl increase in SUA level, risk of all-cause death increased by 16% (HR 255 1.16; 95%CI 1.03-1.32; Fig.3). 256 In retrospective cohort studies, eight studies with 11541 PD patients reported HR 257 and 95% CI of all-cause mortality for 1mg/dl increase in SUA level [14,22,27-258 30,33,35]. When the unit of SUA concentration in the literature was different, 60 μ 259 mol/l was approximately equal to 1mg/dl. In short, each 1mg/dl increase in SUA level 260

262 (HR 0.94; 95% CI 0.88-1.02; Fig.3).

263 **Dose-response relationship between serum uric acid with all-cause mortality**

Most of the included literature [14,21,22,26,28,30,31,33-35] only reported the number

didn't appear to significantly increase the risk of all-cause mortality in PD population

Page 14 of 40

BMJ Open

of outcomes of the entire cohort population, we were unable to obtain the number of
all-cause and CV deaths and person-years in each category. Despite we tried our best
to contact authors by email or phone in order to acquire necessary data for non-linearity
test, only one auther responded and provided relevant data [27]. At last, dose-response
analysis failed.
Secondary outcome
Association of serum uric acid in categories with cardiovascular mortality

One prospective cohort study with 1287 patients reported HR and 95% CI of CV
mortality for the highest SUA category compared with the lowest [21]. Pooled result
of HR in the highest versus the lowest category was 2.63 (95% CI 1.62-4.27). (eFigure1
in the Supplement)

Three retrospective cohort studies with 3748 patients reported HR and 95% CI of CV mortality for the highest versus the lowest SUA category [14,28,29]. And the highest SUA category was not found to increase CV mortality (HR 1.00; 95% CI 0.44-2.31) compared with the lowest category of PD patients (eFigure1 in the Supplement). Association of serum uric acid per 1mg/dl increase with cardiovascular mortality

One prospective cohort study with 1287 patients reported HR and 95% CI of CV mortality for 1mg/dl increase in SUA level [21]. And an increase of 1mg/dl in SUA level was associated with an 34% increased risk of CV mortality (HR 1.34; 95%CI 1.16-1.55; eFigure2 in the Supplement).

Three retrospective cohort studies with 7427 patients reported HR and 95% CI of
CV mortality for 1mg/dl increase in SUA level [14,29,35]. By meta-analysis, each 1

BMJ Open

287	mg/dl increase in SUA level didn't appear to significantly increase the risk of CV death
288	in PD population (HR 0.90; 95% CI 0.76-1.06; eFigure2 in the Supplement).
289	Additional analysis
290	Subgroup analysis and meta-regression
291	We explored the source of heterogeneity for subgroup analysis and meta-regression.
292	Subgroup analysis only included literatures which were on comparisons of the highest
293	versus the lowest category of SUA level, or by change of 1mg/dl increase. The pooled
294	HR (95% CI) and I^2 of subgroup analysis for association of SUA with all-cause and
295	CV mortality were presented in Table 2a and Table 2b, respectively.
296	As mentioned before, whether SUA was a categorical variable or a continuous
297	variable, results of prospective cohort studies differed from those of retrospective
298	studies. Besides, combined with the results of subgroup analysis, when SUA was
299	estimated as a categorical variable, association of higher SUA level with increased all-
300	cause and CV mortality was significant in studies of mainland in China, but not in the
301	rest of the locations. SUA as a continuous variable, relationship of higher CV mortality
302	for 1 mg/dl increase in SUA level was significant in studies of mainland China, but not
303	in the rest of the locations. Furthermore, we analyzed the relevant studies published in
304	the past ten years, and results of studies completed during 2011-2016 were different
305	from the results during 2017-2021 period.
306	In addition, in studies of association between SUA (as a continuous variable) and
307	all-cause mortality, study design, study location, publication years, adjusted for sex and
308	DM were the heterogeneous sources by meta-regression (Table 2a).

309 Test of Publication bias

The funnel plots and Egger's test (t=1.07, p=0.309) indicated that there was no obvious publication bias of studies for association of all-cause mortality and SUA level per 1mg/dl increase. The funnel plot was presented in eFigure3 in the Supplement.

313 Sensitivity analysis

In retrospective cohort studies, primary outcome showed that there was no significant effect on the pooled HR values of other studies with one study removed at a time. The above indicated that the results were robust.

Discussion

Principal findings and comparison with prior reviews

For PD population, previous original studies indicated inconsistent relationship between SUA and mortality. After searching systematically, we found that there were some meta-analyses of investigating the correlation between SUA and mortality in different population [36-39], however, we have not yet found one only for PD patients. A systematic review published in 2016 showed that elevated SUA level was significantly associated with the risk of death in patients with CKD, including dialysis and non-dialysis subjects [40]. Subgroup analysis of this review demonstrated that hyperuricemia was an independent predictor for mortality in PD population, while, this predictive value was not found in the hemodialysis (HD) population. Only 1 prospective cohort study and 2 retrospective cohort studies were included in PD subgroup. In our study, we included a total of 14 cohort studies, of which 2 were prospective studies and 12 were retrospective studies. Quality of all studies was good

BMJ Open

by NOS assessment. Only one prospective cohort study suggested that regardless of
whether SUA was estimated as a continuous or a categorical variable, elevated SUA
level was significantly associated with increased risk of all-cause and CV mortality in
PD patients. Whereas, no significant associations between them in retrospective study.
Considering that only one prospective study [21] was included in analysis, so the result
should be interpreted with caution.

Although the detrimental effect of SUA is obvious, which is an endothelial toxin and plays a role in endothelial dysfunction [41], as a powerful free radical scavenger in human at the same time, SUA may be expected to offer a number of benefits within the CV system in PD patients [42,43]. Besides, the problem of protein loss and malnutrition is prominent in PD population [44]. "Malnutrition-inflammation complex syndrome (MICS)" is believed to be the main cause of high rate of CV atherosclerotic disease and increased mortality and hospitalization in HD patients [45,46]. The underlying mechanism of MICS may also be present in PD patients. As a nutritional marker, SUA might be involved in the MICS axis. The pooled result of the retrospective studies did not find that elevated SUA was associated with increased risk of mortality, perhaps related to complex interaction mechanisms. Further investigations are warranted to clarify the precise mechanisms.

In addition, heterogeneous among included studies was generally high. The different study location was one of the main sources of heterogeneity among studies by meta-regression test. Subgroup analysis results further suggested that hyperuricemia was associated with a high risk of CV death in the PD population in mainland China.

1

As a result, the correlation between the SUA level and the risk of death in different
regions needs to be explored and verified by prospective studies in future.

355 Implications further research

Since the results of prospective and retrospective cohort studies were inconsistent, and different regions of the study seemed to produce different result. Therefore, prospective, multicenter, long term follow-up studies are required in future to explore the correlation between SUA level and the risk of death in different regions, as well as to determine the range of SUA concentrations which can reduce mortality and improve prognosis in PD patients.

Additionally, since PD patients often suffered from underlying diseases and 362 complex conditions. Therefore, confounding factors must be adjusted comprehensively 363 364 in observational study to explore the relationship between etiology and prognosis in future. For PD population, the following confounding factors should be considered to 365 make the conclusion more convincing. Such as: traditional independent risk factors of 366 367 CV events (age, gender, total lipoprotein cholesterol, low or high density lipoprotein cholesterol, hypertension, diabetes, smoking [47]), history of CV, emotion status, 368 residual renal function, the related parameters of PD, the parameters of nutritional 369 status, use of diuretic and lower UA agents and so forth. 370

Besides, necessary information should be reported in detail in study report. Not only can readers become more familiar with the details of the study, but also can conveniently carry out secondary research and avoid waste of research resources.

374 **Conclusions**

BMJ Open

The results of the prospective and retrospective cohort studies were inconsistent. Only one prospective cohort study showed that elevated SUA level was significantly associated with increased risk of all-cause and CV mortality in PD patients. Nevertheless, pooled result of retrospective cohort studies did not appear to indicate a prominent association. So it is necessary to use SUA-lowering agents with caution for PD patients in clinics. And prospective, multicenter, long term follow-up studies are needed in future to investigate the correlation between SUA level and the risk of death in different regions, as well as to explore the range of SUA concentration associated with the lowest mortality in PD patients. Acknowledgements Centre for Evidence-Based Chinese Medicine of Beijing University of Chinese Medicine hosted the study and provided learning guidance to domestic visiting scholars. And we greatly thanked Fang-fang Zhao from Xivuan Hospital, China Academy of Chinese Medical Sciences, for the suggestion during the revision process. 34	Abstract
35	Objectives To analyze the relationship between serum uric acid (SUA), all-cause
36	mortality and cardiovascular (CV) mortality in peritoneal dialysis (PD) patients to
37	inform clinical practice and future research.
38	Design A systematic review of observational studies.
39	Data sources PubMed, Embase, Web of Science, the Cochrane Library, CNKI,
40	SinoMed, VIP and Wan Fang electronic databases were searched from their inception
41	to January 2021 for cohort and case-control studies reporting SUA and mortality in PD
42	patients.
43	Methods Effect estimates were presented as hazard ratios (HR) with 95% confidence

44 intervals (CI) in a meta-analysis using STATA 16.0. Data not suitable for pooling were

45 synthesized qualitatively.

Results Fourteen cohort studies with 24031 patients were included. No case-control studies were identified. For prospective cohort studies, pooled results for the highest SUA category was significantly greater than the lowest for all-cause (1 study: 1287 participants; HR 1.79; 95%CI 1.17-2.75) and CV mortality (1 study; 1287 participants; HR 2.63; 95%CI 1.62-4.27). An increase of 1mg/dl in SUA level was associated with a 16% increased risk of all-cause mortality (1 study; 1287 participants; HR 1.16; 95%CI 1.03-1.32) and 34% increased CV mortality risk (1 study; 1287 participants; HR 1.34; 95%CI 1.16-1.55). For retrospective cohort studies, the highest SUA category did not demonstrate an elevated all-cause mortality (5 studies; 4570 participants; HR 1.09; 95%CI 0.70-1.70) or CV mortality (3 studies; 3748 participants; HR 1.00; 95%CI 0.44-2.31) compared with the lowest SUA category. Additionally, there was no increase in all-cause mortality (8 studies; 11541 participants; HR 0.94; 95%CI 0.88-1.02) or CV mortality (3 studies; 7427 participants; HR 0.90; 95%CI 0.76-1.06) for every 1mg/dl increase in SUA level.

Conclusions Results of prospective and retrospective cohort studies were inconsistent.
 Consequently, prospective, multi-center, long term follow-up studies are required to
 confirm the relationship between SUA and mortality in PD patients.

63 Strengths and limitations of this study

This is the first systematic review of observational studies which has explored the
 relationship between SUA level and mortality in PD patients.

• We used critical appraisal of included studies and subgroup analysis to present the

Page 5 of 42

BMJ Open

results, and proposed future research directions based on the results.

68 • Of the included studies, eleven were conducted in China, two in other Asian countries
69 and one in Europe, this limits the generalizability of our results.

70 • Dose-response relationship could not be determined from these data.

71 Introduction

End-stage renal disease (ESRD) is one of the major diseases affecting human health, and causes enormous pressure and burden on medical care and society. One of the effective treatments for ESRD is peritoneal dialysis (PD) which is characterized by enabling stable hemodynamics, protecting residual renal function (RRF), and demonstrates good removal of middle molecular toxins, and is associated with a low risk of infection, and can be delivered at home [1]. Currently, PD is widely used globally. The total number of people receiving PD worldwide in 2013 reached approximately 220,000 [2]. Of concern is that patients with ESRD treated with dialysis still have high mortality [3]. The identification of potential risk factors has great significance if patients' prognosis and quality of life is to be improved.

⁸²Uric acid (UA) is the final product of purine nucleotide metabolism in humans. ⁸³Previous studies have demonstrated that elevated serum uric acid (SUA) is closely ⁸⁴related to the increased risk of hypertension, peripheral arterial disease, cardiovascular ⁸⁵(CV) event and chronic kidney disease (CKD) in the general population [4-7]. Higher ⁸⁶SUA levels also appear to be an independent risk factor for all-cause and CV mortality ⁸⁷in CKD subjects [8,9]. However, there have been conflicting results about the ⁸⁸relationship between SUA level and risk of death among dialysis patients. In the

89	hemodialysis population, hypouricemia significantly increased mortality [10-12].
90	Nevertheless, the role of SUA in all-cause and CV mortality in PD patients has been
91	controversial. An elevated SUA level has been shown to be an independent risk factor
92	for all-cause and CV mortality in men treated with PD [13]. Another study showed that
93	the prognostic value of SUA in all-cause and CV mortality was weak in PD patients
94	[14]. Hyperuricemia has also been found to predict lower risk of all-cause mortality in
95	PD patients with lower relative appendicular skeletal muscle [15]. In short, the effect
96	of SUA on the prognosis of PD patients appears to be inconsistent.
97	Currently, systematic reviews on the relationship between SUA, all-cause and CV
98	mortality in the PD population are lacking. We hypothesized that there may be an
99	independent correlation between elevated SUA level and mortality in participants with
100	PD. Thus, we systematically analyzed available studies to determine whether this
101	hypothesis could be confirmed.
102	Methods
103	The methods in this review were specified in advance. The review was reported
104	according to the "Meta-analysis of Observational Studies in Epidemiology guidelines"
105	(MOOSE) [16].
106	Eligibility criteria
107	Types of studies
108	Cohort and case-control studies were identified.

109 Participants

110 Participants had to receive PD for more than 3 months. There was no restriction on the

BMJ Open

type of PD, including continuous ambulatory PD, intermittent PD, automated PD, 111 continuous cyclic PD and tidal PD. 112 113 **Exposure factor** Hyperuricemia in PD population was the exposure factor in this study. Either 114 categorization according to baseline SUA level or time-average SUA concentration 115 was acceptable. Definition of hyperuricemia and the categorization for the SUA level 116 was based on the definition reported in each included article. 117 118 Outcome The primary outcome was all-cause mortality and death was determined by the hospital 119 medical record or death certificate. 120 The secondary outcome was CV mortality, defined as a "CV events": coronary 121 events (myocardial infarction, unstable angina), cardio myopathy, cardiac arrest, 122 cardiac dysrhythmia, congestive heart failure, ischemic brain injury, cerebrovascular 123 accident and peripheral vascular disease. The cause of death was determined through 124 125 medical history, hospital medical records or death certificates. 126 **Exclusion criteria** (1) Unable to obtain the following information from the original article. Hazard ratio 127 (HR) and its corresponding 95% confidence interval (CI) (or other data required in 128 order perform the calculation) for all-cause or CV mortality for 1mg/dl change in SUA 129 level, or for the highest versus lowest SUA category or the lowest versus highest 130 category; (2) Cohort studies with a total sample size of less than 100 participants; (3) 131 Studies originating from the same cohort sample, or part of a cohort sample that had 132

been previously published. Only the literature which reported the largest sample sizeand the longest follow-up could be included.

135 Search strategy

Two authors (X.X. and H.C.) searched the following Chinese and English databases from their inception to 15th January 2021. Chinese databases included China National Knowledge Infrastructure (CNKI), SinoMed, Chinese Science and Technology Journal Database (VIP), and Wan Fang Database. English databases included PubMed, EMBASE, the Cochrane Library, and Web of Science. Trial registers including Clinical Trials. gov and the World Health Organization International Clinical Trials Registry Platform were also searched. Additionally, related reviews, conference papers, references lists and gray literatures were also searched manually. No language or publication type was imposed, published abstracts were also considered. If the retrieved literature had missing information, it was necessary to contact the author via email to obtain the data to ensure that literature could be included. Taking "PubMed" as an example, the searching strategy was as follows: ("Uric Acid" [Mesh] OR "Uric Acid" [Title/Abstract] OR "serum uric acid"[Title/Abstract]) AND ("Mortality"[Mesh] OR "Mortality"[Title/Abstract]) AND ("Peritoneal Dialysis" [Mesh] OR "Peritoneal Dialysis"[Title/Abstract] OR "PD"[Title/Abstract] OR "continuous ambulatory PD" [Title/Abstract] OR "CAPD" [Title/Abstract] OR "intermittent PD" [Title/Abstract] OR "IPD" [Title/Abstract] OR "automated PD" [Title/Abstract] OR "APD" [Title/Abstract] OR "continuous cyclic PD"[Title/Abstract] OR "CCPD"[Title/Abstract] OR "tidal PD"[Title/Abstract] OR "TPD"[Title/Abstract]). The searching strategies for other

Page 9 of 42

BMJ Open

databases are presented in eTable1 in the Supplement.

156 Studies selection and data extraction

The titles and the abstracts were initially screened, then the full-text versions were checked according to the inclusion and exclusion criteria. Two authors (X.X. and O.L.) examined the full text to identify the eligible studies independently. Two authors (X.X. and H.C.) extracted data independently and entered information into a data extraction sheet. Disagreements on study selection and data extraction were resolved by consulting corresponding author JP Liu. The following information was extracted from each included study: first author, publication year, age, gender, study design, dialysis duration, sample size, study location, center, length of follow up, categories according to SUA, comparison, adjustments, and adjusted HR (95%CI).

166 Methodological quality assessment

The Newcastle-Ottawa Quality Assessment Scale (NOS) was used to appraise the quality of observational studies [17]. NOS allocates a maximum of 9 points for quality of selection, comparability, and outcome of study population. Two authors (X.X. and X.Y.J.) appraised the quality of included studies independently. Any disagreements were resolved by discussion with corresponding author JP Liu. Overall study quality scores were defined as poor (0–3), fair (4–6), or good (7–9).

173 Statistical analysis

SUA was analyzed not only as a categorical variable, but also as a continuous variable
in the included studies. The statistical analysis for the overall relationship between SUA
level and death risk (all-cause and CV mortality) were based on the random effects

model and on comparisons of the highest versus the lowest category of SUA level, or
by increase of 1mg/dl. HR and 95% CI were used as effect indicators. HR and
corresponding 95% CI of each study were transformed to their natural logarithm (lnHR,
lnlCI and lnUCI), and overall HR and its 95% CI was calculated by exponentiation of
the pooled lnHR, lnlCI and lnUCI.

If data on cases, person-years, and HR and 95% CI for each category were available in the included studies, then a dose-response analysis would be performed to further explore the relationship between SUA and mortality. The potential non-linearity association was examined by modeling SUA levels using restricted cubic splines with three knots at 25, 50, and 75% of the distribution. We assigned the median or middle point of the upper and lower boundaries in each category as the corresponding dose to the related HR for each study. In general, if there is a dose-response relationship between SUA and mortality, and *P* value for non-linear < 0.05, non-linear regression model should be considered. When the P value was close to the critical value of 0.05, both linear and non-linear models needed to be fitted.

The square (I^2) was applied to test the statistical heterogeneity among studies (Higgins and Thompson, 2003) [18]. When $I^2 > 85\%$, we believed that the results could not be pooled. Data not suitable for statistical pooling were synthesized qualitatively. To explore the source of heterogeneity among studies, subgroup analyses were conducted according to study design, study location, publication years, adjustment for sex, adjustment for DM and adjustment for albumin. Additionally, the meta-regression analysis was also performed to detect potential heterogeneity based on the above

variables when about 10 studies were included. Sensitivity analysis was performed
removing one study at a time to explore the robustness of results if data were available.
The possibility of publication bias was detected by funnel plots and Egger's test if there
were about 10 studies. STATA16.0 software (StataCorp, College Station, Texas, 77845
USA) was used for data analysis.

204 Patient and Public Involvement statement

Patients or the public WERE NOT involved in the design, or conduct, or reporting, ordissemination plans of our study.

207 **Results**

208 Search results

Two hundred and forty-two relevant citations were retrieved. After scanning the full 209 210 texts, five articles were excluded. Cohort samples from the same study were excluded [13,15,19], and only the studies with the largest sample size and the longest follow-up 211 time were included [20,21]. In addition, a published abstract was excluded, because the 212 total sample size of the entire cohort was only 60 participants [22]. Another study was 213 excluded due to its pooled effect estimation which was reported as an odds ratio (OR) 214 with 95% CI [23]. Finally, fourteen studies were eligible for this review. Details of the 215 search and selection process are illustrated in Fig.1. 216 **Characteristic of included trials** 217

A total of fourteen studies consisting of 24031 participants were included [14,20,21,24-

219 34]. All were cohort studies, including prospective and retrospective studies. The main

characteristics of included studies are given in Table 1 and Table2.

221	Methodological quality of included studies
221	methodological quality of methodol studies

The overall quality of included studies was good with a mean NOS score of 7.57 (range 7–9). All studies scored greater than or equal to 7 (eTable2 in the Supplement). In terms of "comparability", the most important confounding factors that required adjustment were: estimated glomerular filtration rate (eGFR) or serum creatinine (Scr) or urinary volume (UV) or residual renal function (RRF). The above indicators can reflect the patient's current residual renal function status. In addition, according to the literature and clinical observations, other confounding factors needing adjustment should include gender, age, diabetes history, cardiovascular disease (CVD) history, Kt/v (urea clearance index, representing dialysis adequacy), use of UA-lowering drugs, and serum albumin (representing nutritional status).

Primary outcome

233 Relationship between serum uric acid by categories and all-cause mortality

In order to reduce the heterogeneity of methodology, we discussed the results according
to different study designs. For prospective cohort studies, the summary HR and 95%
CI of all-cause mortality for the highest SUA category compared with the lowest
category came from one study which included 1287 patients [20]. As presented in Fig.2,
the pooled result of the highest SUA category was significantly higher than the lowest
for all-cause mortality (HR 1.79; 95% CI 1.17-2.75).

In retrospective cohort studies, five studies with 4570 patients reported HR and 95% CI of all-cause mortality for the highest versus the lowest SUA category [14,27,28,32,33]. All cause mortality (HR 1.09; 95% CI 0.70-1.70; Fig.2) was not Page 13 of 42

significantly elevated compared with the lowest category of PD patients.

HR and corresponding 95% CI were reported in three retrospective cohort studies
for the lowest versus the highest SUA category [25,26,30]. Among them, the data from
one article [26] was supplemented by the corresponding author via e-mail. The pooled
HR was 1.52 (95%CI 0.79-2.89), with heterogeneity of I²=32.8%. *Relationship between serum uric acid per 1mg/dl increase and all-cause mortality*Only one prospective study with 1287 PD patients reported HR and 95% CI of allcause mortality for every 1mg/dl increase in SUA level [20]. The pooled result showed

that for every 1mg/dl increase in SUA level, risk of all-cause death increased by 16%

252 (HR 1.16; 95%CI 1.03-1.32; Fig.3).

For the retrospective cohort studies, eight studies with 11541 PD patients reported HR and 95% CI of all-cause mortality for every 1mg/dl increase in SUA level [14,21,26-29,32,34]. When the units of SUA concentration in the literature were different, 60μ mol/l was approximately equal to 1mg/dl. In short, each 1mg/dl increase in SUA level did not appear to significantly increase the risk of all-cause mortality in the PD population (HR 0.94; 95% CI 0.88-1.02; Fig.3).

259 Dose-response relationship between serum uric acid and all-cause mortality

Most of the included studies [14,20,21,25,27,29,30,32-34] only reported the number of outcomes for the entire cohort population. It was not possible to obtain the number of all-cause and CV deaths and person-years for each category. We tried our best to contact authors by email or phone in order to acquire the necessary data for the nonlinearity test, only one author responded and provided relevant data [26]. A dose-

response analysis was not possible.

266 Secondary outcome

267 **Relationship between serum uric acid by categories and cardiovascular mortality**

One prospective cohort study with 1287 patients reported HR and 95% CI of CV mortality for the highest SUA category compared with the lowest [20]. The pooled result of HR comparing the highest versus the lowest category was 2.63 (95% CI 1.62-

271 4.27). (Fig.4).

Three retrospective cohort studies with 3748 patients reported HR and 95% CI of CV mortality for the highest versus the lowest SUA category [14,27,28]. The highest SUA category was no more in terms of elevated CV mortality (HR 1.00; 95% CI 0.44-275 2.31) compared with the lowest category of PD patients. (Fig.4).

276 Relationship between serum uric acid per 1mg/dl increase and cardiovascular mortality

One prospective cohort study with 1287 patients reported HR and 95% CI of CV
mortality for per 1mg/dl increase in SUA level [20]. An increase of each 1mg/dl in
SUA level was associated with a 34% increased risk of CV mortality (HR 1.34; 95%CI
1.16-1.55). (Fig.5).

Three retrospective cohort studies with 7427 patients reported HR and 95% CI of CV mortality per1mg/dl increase in SUA level [14,28,34]. Meta-analysis showed that each 1 mg/dl increase in SUA level did not appear to significantly increase the risk of CV death in PD population (HR 0.90; 95% CI 0.76-1.06). (Fig.5).

- 285 Additional analysis
- 286 Subgroup analysis and meta-regression

Page 15 of 42

BMJ Open

We explored the source of heterogeneity through subgroup analysis and metaregression. Subgroup analysis only included literature which compared the highest
versus the lowest category of SUA level, or explored a change of 1mg/dl increase. The
pooled HR (95% CI) and I² of subgroup analysis of the relationship between SUA and
all-cause and CV mortality are presented in Table 3 and Table 4, respectively.
As mentioned before, whether SUA was a categorical variable or a continuous
variable, the results of the prospective cohort study differed from those of retrospective

studies. Besides, combined with the results of subgroup analysis, when SUA was estimated as a categorical variable, the association of higher SUA level with increased all-cause and CV mortality was significant in studies from mainland China, but not in other countries. SUA as a continuous variable showed that the relationship of higher CV mortality for 1 mg/dl increase in SUA level was significant in studies from mainland China, but not elsewhere. Furthermore, we analyzed the relevant studies published in the past ten years, and results of studies completed during 2011-2016 were different from the results during 2017-2021 period.

In addition, in studies of the relationship between SUA (as a continuous variable)
 and all-cause mortality, study design, study location, publication years, adjusted for sex
 and DM were heterogeneous by meta-regression (Table 3).

305 Test of Publication bias

Funnel plots and Egger's test (t=1.07, p=0.309) indicated there was no obvious publication bias of studies for the relationship between all-cause mortality and SUA level per 1mg/dl increase. The funnel plot is presented in eFigure1 in the Supplement.

Sensitivity analysis

In retrospective cohort studies, results of primary outcome showed there was no significant effect on the pooled HR values of other studies with one study removed at a time. The above indicated the results were robust.

Discussion

Principal findings and comparison with prior reviews

For PD population, previous original studies indicated inconsistent relationship between SUA and mortality. After searching systematically, we found that there were some meta-analyses investigating the correlation between SUA and mortality in different populations [35-38], however, we have not yet found a review only of PD patients. A systematic review published in 2016 showed that elevated SUA level was significantly associated with the risk of death in patients with CKD, including dialysis and non-dialysis subjects [39]. Subgroup analysis in this review demonstrated that hyperuricemia was an independent predictor for mortality in PD population, while, this predictive value was not found in the hemodialysis (HD) population. As only 1 prospective cohort study and 2 retrospective cohort studies were included in the subgroup analysis, results should be interpreted with caution.

In our study, we included a total of 14 cohort studies, of which 2 were prospective studies and 12 were retrospective studies. There was no obvious publication bias of studies according to funnel plots and Egger's test. Researchers can not control the process of data accumulation in retrospective cohort studies, but researchers can directly acquire relevant data on exposure and outcome according to the study design

Page 17 of 42

BMJ Open

in prospective studies, so the risk of bias is small. Thus, instead of pooling results of the two studies, we reported them individually. Only one prospective cohort study suggested that regardless of whether SUA was estimated as a continuous or a categorical variable, elevated SUA level was significantly associated with increased risk of all-cause and CV mortality in PD patients. Whereas, there was no significant associations between them in the retrospective studies. Below we have attempted to discuss the inconsistency of the results from the aspects of participants, exposure, comparability and outcomes.

First of all, the prospective cohort study clearly indicated that participants on PD were consecutively enrolled. It is well known that consecutive recruitment is very important to reduce selection bias. While, in some retrospective studies, the process of enrollment was not detailed. The follow-up of the participants was also a prominent issue, including the duration and adequacy of follow-up and the rate of loss to follow-up. In a prospective study, effective measures can be taken to reduce the loss to follow-up rate to avoid bias. The rate of loss to follow-up in a prospective study by Xia X et al. (2016) was only 3.5% [20], but in some retrospective cohorts, the adequacy and lost follow-up rates were not reported.

Second, hyperuricemia in the PD population was the exposure factor of this study. Both prospective and retrospective cohort studies, the definition of hyperuricemia and the categorization for the SUA level was based on the definition provided in each included article. It should be noted that in retrospective multi-center studies, the measurement methods of SUA may not be uniform across centers. This may lead to

353 measurement bias and have a slight impact on results.

Third, control of the most important and other confounding factors is very important for the comparability between the groups. The most important confounding factors included indicators that can reflect the patient's current residual renal function status. Other confounding factors need to be adjusted and should include gender, age, diabetes history, CVD history, Kt/v, use of UA-lowering drugs, and serum albumin. Most of the studies did not adjust for all potential risk factors. For example, the prospective study of Xia X et al. (2016) lacked adjustment for the confounding factor Kt/v [20]. Therefore, we can not exclude the potential impact of these uncontrolled confounding factors.

Regarding the outcomes, the definition of all-cause and cardiovascular death was clear. However, the handling of patients transferring to hemodialysis therapy, loss to follow-up, and renal transplantation was different for prospective and retrospective studies. The above information from patients was used as censoring data for survival analysis in the prospective study [20]. Whereas, in some retrospective studies, they were directly excluded from the study [32]. This may affect the results and lead to inconsistencies between the prospective and retrospective studies. Although the risk of bias in the design type of prospective study was relatively small, the interpretation of the results should still be cautious due to the limited quality and quantity of prospective study.

SUA, known for its detrimental effect, is an endothelial toxin and plays a role in
endothelial dysfunction [40]. However, as a powerful free radical scavenger in human

Page 19 of 42

BMJ Open

at the same time, SUA may be expected to offer a number of benefits within the CV system in PD patients [41,42]. Besides, the problem of protein loss and malnutrition is prominent in PD population [43]. "Malnutrition-inflammation complex syndrome (MICS)" is believed to be the main cause of the high rate of CV atherosclerotic disease and increased mortality and hospitalization in HD patients [44,45]. The underlying mechanism of MICS may also be present in PD patients. As a nutritional marker, SUA might be involved in the MICS axis. Therefore, the relationship between SUA and mortality in PD patients is a complex proposition. Taking into account the feature of SUA itself, we hypothesize that both extremely low and high SUA level may increase the risk of death. In our study, we also would like to explore the dose-response relationship between SUA level and mortality in PD population, but in the end the analysis to explore a dose-response relationship was impossible due to insufficient data. Further investigations are warranted to clarify this relationship and explore the range of SUA concentration associated with the lowest mortality in the PD patients.

Moreover, in addition to different study designs, different study location was also one of the main sources of heterogeneity among studies according to the metaregression test. Subgroup analysis results further suggested hyperuricemia was associated with a high risk of CV death in PD population only in mainland China. As a result, the relationship between SUA level and the risk of death in different regions needs to be explored and verified by prospective studies in future.

- **Implications further research**
- 396 Since the results of prospective and retrospective cohort studies were inconsistent, and

> the different regions seemed to lead to different results, prospective, multicenter, long term follow-up studies are required in future. It is important to explore the relationship between SUA level and the risk of death in different regions, as well as to determine the range of SUA concentrations which can reduce mortality and improve prognosis in the PD patients.

> Additionally, since PD patients often suffer from underlying diseases and complex conditions, adjustment is required for confounding factors to explore the relationship between these factors and prognosis. For the PD population, the following confounding factors should be considered to make the evidence more compelling. Such as: traditional independent risk factors of CV events (age, gender, total lipoprotein cholesterol, low or high density lipoprotein cholesterol, hypertension, diabetes, smoking [46]), history of CV, emotion status, residual renal function, the related parameters of PD, the parameters of nutritional status, use of diuretic and lower UA agents etc.

411 Comprehensive information should be reported in detail in the study report so that
412 readers can become more familiar with the details of the study, and can conduct
413 secondary research to avoid wasting research resources.

414 Study limitations

There were several limitations in this review. Systematic reviews of observational studies can provide a higher level of evidence, but they also have methodological limitations. For example, the included original studies may differ in their design, data collection methods, and definitions of exposure, confounding factors and outcomes.

BMJ Open

These differences may have a slight influence on the true effect size. Second, in this review, the included studies were mainly from Asian populations (only one from Europe), and the generalizability of the results was limited. Third, in spite of many important confounding factors that to be adjusted in the studies, residual and unknown confounding factors can not be entirely excluded. Fourth, the duration of follow up in all studies was less than 5 years. It is difficult to determine long-term impact of elevated SUA level on mortality. Finally, some necessary data was not obtained, and the exploration of dose-response relationship could not be conducted, but will need to be determined in future studies.

Conclusions

The results from the prospective and retrospective cohort studies were inconsistent. Only one prospective cohort study showed that elevated SUA level was significantly associated with increased risk of all-cause and CV mortality in PD patients. Nevertheless, the pooled result of retrospective cohort studies did not appear to indicate a prominent association. So it is necessary to use SUA-lowering agents with caution for PD patients in clinics. International prospective, multicenter, long term follow-up studies are needed in the future to investigate the relationship between SUA level and the risk of death, and to explore the range of SUA concentrations associated with the lowest mortality in the PD patients.

Design A systematic review of observational studies. Data sources PubMed, Embase, Web of Science, the Cochrane Library, CNKI, SinoMed, VIP and Wan Fang databases were searched from their inception to January 2021 for cohort and case-control studies reporting SUA and mortality in PD patients. 			

44 hazard ratios (HR) with 95% confidence intervals (CI) in a meta-analysis using STATA

45	16.0. Data not suitable for pooling were synthesized qualitatively.
46	Results Fourteen cohort studies with 24031 patients were included. No case-control
47	studies were identified. For prospective cohort studies, pooled results for the highest
48	SUA category was significantly greater than the lowest for all-cause (1 study; 1287
49	participants; HR 1.79; 95%CI 1.17-2.75) and CV mortality (1 study; 1287 participants;
50	HR 2.63; 1.62-4.27). An increase of 1mg/dl in SUA level was associated with a 16%
51	increased risk of all-cause mortality (1 study; 1287 participants; HR 1.16; 1.03-1.32)
52	and 34% increased CV mortality risk (1 study; 1287 participants; HR 1.34; 1.16-1.55).
53	For retrospective cohort studies, the highest SUA category did not demonstrate an
54	elevated all-cause (5 studies; 4570 participants; HR 1.09; 0.70-1.70) or CV mortality
55	(3 studies; 3748 participants; HR 1.00; 0.44-2.31) compared with the lowest SUA
56	category. Additionally, there was no increase in all-cause (8 studies; 11541 participants;
57	HR 0.94; 0.88-1.02) or CV mortality (3 studies; 7427 participants; HR 0.90; 0.76-1.06)
58	for every 1mg/dl increase in SUA level.
59	Conclusions Results of prospective and retrospective cohort studies were inconsistent.
60	Consequently, prospective, multi-center, long-term follow-up studies are required to
61	confirm the relationship between SUA and mortality in PD patients.

Strengths and limitations of this study

• This is the first systematic review of observational studies which has explored the relationship between SUA level and mortality in PD patients.

- We used critical appraisal of included studies and subgroup analysis to present the
- results, and proposed future research directions based on the results.

67 • Of the included studies, eleven were conducted in China, two in other Asian countries
68 and one in Europe, this limits the generalizability of our results.

69 • Dose-response relationship could not be determined from these data.

70 Introduction

End-stage renal disease (ESRD) is one of the major diseases affecting human health, 71 and causes enormous pressure and burden on medical care and society. One of the 72 effective treatments for ESRD is peritoneal dialysis (PD) which is characterized by 73 enabling stable hemodynamics, protecting residual renal function (RRF), and 74 75 demonstrates good removal of middle molecular toxins, and is associated with a low risk of infection, and can be delivered at home [1]. Currently, PD is widely used 76 globally. The total number of people receiving PD worldwide in 2013 reached 77 78 approximately 220,000 [2]. Of concern is that patients with ESRD treated with dialysis still have high mortality [3]. The identification of potential risk factors has great 79 significance if patients' prognosis and quality of life is to be improved. 80

Uric acid (UA) is the final product of purine nucleotide metabolism in humans. 81 Previous studies have demonstrated that elevated serum uric acid (SUA) is closely 82 related to the increased risk of hypertension, peripheral arterial disease, cardiovascular 83 (CV) event and chronic kidney disease (CKD) in the general population [4-7]. Higher 84 SUA levels also appear to be an independent risk factor for all-cause and CV mortality 85 in CKD subjects [8,9]. However, there have been conflicting results about the 86 87 relationship between SUA level and risk of death among dialysis patients. In the hemodialysis population, hypouricemia significantly increased mortality [10-12]. 88

60	

89	Nevertheless, the role of SUA in all-cause and CV mortality in PD patients has been
90	controversial. An elevated SUA level has been shown to be an independent risk factor
91	for all-cause and CV mortality in men treated with PD [13]. Another study showed that
92	the prognostic value of SUA in all-cause and CV mortality was weak in PD patients
93	[14]. Hyperuricemia has also been found to predict lower risk of all-cause mortality in
94	PD patients with lower relative appendicular skeletal muscle [15]. In short, the effect
95	of SUA on the prognosis of PD patients appears to be inconsistent.
96	Currently, systematic reviews on the relationship between SUA, all-cause and CV
97	mortality in the PD population are lacking. We hypothesized that there may be an
98	independent correlation between elevated SUA level and mortality in participants with
99	PD. Thus, we systematically analyzed available studies to determine whether this
100	hypothesis could be confirmed.
100 101	hypothesis could be confirmed. Methods
101	Methods
101 102	Methods The methods in this review were specified in advance. The review was reported according to the "Meta-analysis of Observational Studies in Epidemiology guidelines"

2		
3 4 5	111	continuous cyclic PD and tidal PD.
5 6 7 8	112	Exposure factor
9 10	113	Hyperuricemia in PD population was the exposure factor in this study. Either
11 12 13	114	categorization according to baseline SUA level or time-average SUA concentration
14 15	115	was acceptable. Definition of hyperuricemia and the categorization for the SUA level
16 17 18	116	was based on the definition reported in each included article.
19 20	117	Outcome
21 22 23	118	The primary outcome was all-cause mortality and death was determined by the hospital
24 25 26	119	medical record or death certificate.
27 28	120	The secondary outcome was CV mortality, defined as a "CV events": coronary
29 30 31	121	events (myocardial infarction, unstable angina), cardio myopathy, cardiac arrest,
32 33	122	cardiac dysrhythmia, congestive heart failure, ischemic brain injury, cerebrovascular
34 35 36	123	accident and peripheral vascular disease. The cause of death was determined through
37 38 39	124	medical history, hospital medical records or death certificates.
40 41	125	Exclusion criteria
42 43 44	126	(1) Unable to obtain the following information from the original article. Hazard ratio
45 46	127	(HR) and its corresponding 95% confidence interval (CI) (or other data required in
47 48 49	128	order perform the calculation) for all-cause or CV mortality for 1mg/dl change in SUA
50 51	129	level, or for the highest versus lowest SUA category or the lowest versus highest
52 53 54 55	130	category; (2) Cohort studies with a total sample size of less than 100 participants; (3)
55 56 57	131	Studies originating from the same cohort sample, or part of a cohort sample that had
58 59 50	132	been previously published. Only the literature which reported the largest sample size

and the longest follow-up could be included.

Search strategy

Two authors (X.X. and H.C.) searched the following Chinese and English databases from their inception to 15th January 2021. Chinese databases included China National Knowledge Infrastructure (CNKI), SinoMed, Chinese Science and Technology Journal Database (VIP), and Wan Fang Database. English databases included PubMed, EMBASE, the Cochrane Library, and Web of Science. Trial registers including Clinical Trials. gov and the World Health Organization International Clinical Trials Registry Platform were also searched. Additionally, related reviews, conference papers, references lists and gray literatures were also searched manually. No language or publication type was imposed, published abstracts were also considered. If the retrieved literature had missing information, it was necessary to contact the author via email to obtain the data to ensure that literature could be included. Taking "PubMed" as an example, the searching strategy was as follows: ("Uric Acid" [Mesh] OR "Uric Acid" [Title/Abstract] OR "serum uric acid"[Title/Abstract]) AND ("Mortality"[Mesh] OR "Mortality"[Title/Abstract]) AND ("Peritoneal Dialysis"[Mesh] OR "Peritoneal Dialysis"[Title/Abstract] OR "PD"[Title/Abstract] OR "continuous ambulatory PD" [Title/Abstract] OR "CAPD" [Title/Abstract] OR "intermittent PD" [Title/Abstract] OR "IPD" [Title/Abstract] OR "automated PD" [Title/Abstract] OR "APD" [Title/Abstract] OR "continuous cyclic PD"[Title/Abstract] OR "CCPD"[Title/Abstract] OR "tidal PD"[Title/Abstract] OR "TPD"[Title/Abstract]). The searching strategies for other databases are presented in eTable1 in the Supplement.

Page 9 of 42

Studies selection and data extraction

BMJ Open

156	The titles and the abstracts were initially screened, then the full-text versions were
157	checked according to the inclusion and exclusion criteria. Two authors (X.X. and Q.L.)
158	examined the full text to identify the eligible studies independently. Two authors (X.X.
159	and H.C.) extracted data independently and entered information into a data extraction
160	sheet. Disagreements on study selection and data extraction were resolved by
161	consulting corresponding author JP Liu. The following information was extracted from
162	each included study: first author, publication year, age, gender, study design, dialysis
163	duration, sample size, study location, center, length of follow up, categories according
164	to SUA, comparison, adjustments, and adjusted HR (95%CI).

165 Methodological quality assessment

The Newcastle-Ottawa Quality Assessment Scale (NOS) was used to appraise the quality of observational studies [17]. NOS allocates a maximum of 9 points for quality of selection, comparability, and outcome of study population. Two authors (X.X. and X.Y.J.) appraised the quality of included studies independently. Any disagreements were resolved by discussion with corresponding author JP Liu. Overall study quality scores were defined as poor (0–3), fair (4–6), or good (7–9).

172 Statistical analysis

SUA was analyzed not only as a categorical variable, but also as a continuous variable
in the included studies. The statistical analysis for the overall relationship between SUA
level and death risk (all-cause and CV mortality) were based on the random effects
model and on comparisons of the highest versus the lowest category of SUA level, or

by increase of 1mg/dl. HR and 95% CI were used as effect indicators. HR and
corresponding 95% CI of each study were transformed to their natural logarithm (lnHR,
lnlCI and lnUCI), and overall HR and its 95% CI was calculated by exponentiation of
the pooled lnHR, lnlCI and lnUCI.

If data on cases, person-years, and HR and 95% CI for each category were available in the included studies, then a dose-response analysis would be performed to further explore the relationship between SUA and mortality. The potential non-linearity association was examined by modeling SUA levels using restricted cubic splines with three knots at 25, 50, and 75% of the distribution. We assigned the median or middle point of the upper and lower boundaries in each category as the corresponding dose to the related HR for each study. In general, if there is a dose-response relationship between SUA and mortality, and P value for non-linear < 0.05, non-linear regression model should be considered. When the P value was close to the critical value of 0.05, both linear and non-linear models needed to be fitted.

The square (1^2) was applied to test the statistical heterogeneity among studies (Higgins and Thompson, 2003) [18]. When $I^2 > 85\%$, we believed that the results could not be pooled. Data not suitable for statistical pooling were synthesized qualitatively. To explore the source of heterogeneity among studies, subgroup analyses were conducted according to study design, study location, publication years, adjustment for sex, adjustment for DM and adjustment for albumin. Additionally, the meta-regression analysis was also performed to detect potential heterogeneity based on the above variables when about 10 studies were included. Sensitivity analysis was performed

removing one study at a time to explore the robustness of results if data were available. 199 The possibility of publication bias was detected by funnel plots and Egger's test if there 200 were about 10 studies. STATA16.0 software (StataCorp, College Station, Texas, 77845 201 USA) was used for data analysis. 202 **Patient and Public Involvement statement** 203 Patients or the public WERE NOT involved in the design, or conduct, or reporting, or 204 dissemination plans of our study. 205 Results 206 207 **Search results** Two hundred and forty-two relevant citations were retrieved. After scanning the full 208 texts, five articles were excluded. Cohort samples from the same study were excluded 209 210 [13,15,19], and only the studies with the largest sample size and the longest follow-up time were included [20,21]. In addition, a published abstract was excluded, because the 211 total sample size of the entire cohort was only 60 participants [22]. Another study was 212 213 excluded due to its pooled effect estimation which was reported as an odds ratio (OR) with 95% CI [23]. Finally, fourteen studies were eligible for this review. Details of the 214 search and selection process are illustrated in Fig.1. 215 **Characteristic of included trials** 216

- A total of fourteen studies consisting of 24031 participants were included [14,20,21,24-
- 218 34]. All were cohort studies, including prospective and retrospective studies. The main
- characteristics of included studies are given in Table 1 and Table2.
- 220 Methodological quality of included studies

The overall quality of included studies was good with a mean NOS score of 7.57 (range 7–9). All studies scored greater than or equal to 7 (eTable2 in the Supplement). In terms of "comparability", the most important confounding factors that required adjustment were: estimated glomerular filtration rate (eGFR) or serum creatinine (Scr) or urinary volume (UV) or residual renal function (RRF). The above indicators can reflect the patient's current residual renal function status. In addition, according to the literature and clinical observations, other confounding factors needing adjustment should include gender, age, diabetes history, cardiovascular disease (CVD) history, Kt/v (urea clearance index, representing dialysis adequacy), use of UA-lowering drugs, and serum albumin (representing nutritional status).

Primary outcome

232 Relationship between serum uric acid by categories and all-cause mortality

In order to reduce the heterogeneity of methodology, we discussed the results according
to different study designs. For prospective cohort studies, the summary HR and 95%
CI of all-cause mortality for the highest SUA category compared with the lowest
category came from one study which included 1287 patients [20]. As presented in Fig.2,
the pooled result of the highest SUA category was significantly higher than the lowest
for all-cause mortality (HR 1.79; 95% CI 1.17-2.75).

In retrospective cohort studies, five studies with 4570 patients reported HR and 95% CI of all-cause mortality for the highest versus the lowest SUA category [14,27,28,32,33]. All cause mortality (HR 1.09; 95% CI 0.70-1.70; Fig.2) was not significantly elevated compared with the lowest category of PD patients. Page 13 of 42

HR and corresponding 95% CI were reported in three retrospective cohort studies
for the lowest versus the highest SUA category [25,26,30]. Among them, the data from
one article [26] was supplemented by the corresponding author via e-mail. The pooled
HR was 1.52 (95%CI 0.79-2.89), with heterogeneity of I²=32.8%.

247 Relationship between serum uric acid per 1mg/dl increase and all-cause mortality

Only one prospective study with 1287 PD patients reported HR and 95% CI of allcause mortality for every 1mg/dl increase in SUA level [20]. The pooled result showed
that for every 1mg/dl increase in SUA level, risk of all-cause death increased by 16%
(HR 1.16; 95%CI 1.03-1.32; Fig.3).

For the retrospective cohort studies, eight studies with 11541 PD patients reported HR and 95% CI of all-cause mortality for every 1mg/dl increase in SUA level [14,21,26-29,32,34]. When the units of SUA concentration in the literature were different, 60μ mol/l was approximately equal to 1mg/dl. In short, each 1mg/dl increase in SUA level did not appear to significantly increase the risk of all-cause mortality in the PD population (HR 0.94; 95% CI 0.88-1.02; Fig.3).

258 Dose-response relationship between serum uric acid and all-cause mortality

Most of the included studies [14,20,21,25,27,29,30,32-34] only reported the number of outcomes for the entire cohort population. It was not possible to obtain the number of all-cause and CV deaths and person-years for each category. We tried our best to contact authors by email or phone in order to acquire the necessary data for the nonlinearity test, only one author responded and provided relevant data [26]. A doseresponse analysis was not possible.

265 Secondary outcome

266 **Relationship between serum uric acid by categories and cardiovascular mortality**

One prospective cohort study with 1287 patients reported HR and 95% CI of CV mortality for the highest SUA category compared with the lowest [20]. The pooled result of HR comparing the highest versus the lowest category was 2.63 (95% CI 1.62-4.27). (Fig.4).

Three retrospective cohort studies with 3748 patients reported HR and 95% CI of CV mortality for the highest versus the lowest SUA category [14,27,28]. The highest SUA category was no more in terms of elevated CV mortality (HR 1.00; 95% CI 0.44-274 2.31) compared with the lowest category of PD patients. (Fig.4).

275 Relationship between serum uric acid per 1mg/dl increase and cardiovascular mortality

One prospective cohort study with 1287 patients reported HR and 95% CI of CV mortality for per 1mg/dl increase in SUA level [20]. An increase of each 1mg/dl in SUA level was associated with a 34% increased risk of CV mortality (HR 1.34; 95%CI 1.16-1.55). (Fig.5).

Three retrospective cohort studies with 7427 patients reported HR and 95% CI of CV mortality per1mg/dl increase in SUA level [14,28,34]. Meta-analysis showed that each 1 mg/dl increase in SUA level did not appear to significantly increase the risk of CV death in PD population (HR 0.90; 95% CI 0.76-1.06). (Fig.5).

- 284 Additional analysis
- 285 Subgroup analysis and meta-regression
 - 286 We explored the source of heterogeneity through subgroup analysis and meta-

Page 15 of 42

BMJ Open

regression. Subgroup analysis only included literature which compared the highest versus the lowest category of SUA level, or explored a change of 1mg/dl increase. The pooled HR (95% CI) and I² of subgroup analysis of the relationship between SUA and all-cause and CV mortality are presented in Table 3 and Table 4, respectively. As mentioned before, whether SUA was a categorical variable or a continuous variable, the results of the prospective cohort study differed from those of retrospective studies. Besides, combined with the results of subgroup analysis, when SUA was estimated as a categorical variable, the association of higher SUA level with increased all-cause and CV mortality was significant in studies from mainland China, but not in other countries. SUA as a continuous variable showed that the relationship of higher CV mortality for 1 mg/dl increase in SUA level was significant in studies from mainland China, but not elsewhere. Furthermore, we analyzed the relevant studies published in the past ten years, and results of studies completed during 2011-2016 were different from the results during 2017-2021 period. In addition, in studies of the relationship between SUA (as a continuous variable) and all-cause mortality, study design, study location, publication years, adjusted for sex and DM were heterogeneous by meta-regression (Table 3).

Funnel plots and Egger's test (t=1.07, p=0.309) indicated there was no obvious publication bias of studies for the relationship between all-cause mortality and SUA level per 1mg/dl increase. The funnel plot is presented in eFigure1 in the Supplement. **Sensitivity analysis**

Test of Publication bias

In retrospective cohort studies, results of primary outcome showed there was no
significant effect on the pooled HR values of other studies with one study removed at
a time. The above indicated the results were robust.

312 Discussion

313 Principal findings and comparison with prior reviews

For PD population, previous original studies indicated inconsistent relationship between SUA and mortality. After searching systematically, we found that there were some meta-analyses investigating the correlation between SUA and mortality in different populations [35-38], however, we have not yet found a review only of PD patients. A systematic review published in 2016 showed that elevated SUA level was significantly associated with the risk of death in patients with CKD, including dialysis and non-dialysis subjects [39]. Subgroup analysis in this review demonstrated that hyperuricemia was an independent predictor for mortality in PD population, while, this predictive value was not found in the hemodialysis (HD) population. As only 1 prospective cohort study and 2 retrospective cohort studies were included in the subgroup analysis, results should be interpreted with caution.

In our study, we included a total of 14 cohort studies, of which 2 were prospective studies and 12 were retrospective studies. There was no obvious publication bias of studies according to funnel plots and Egger's test. Researchers can not control the process of data accumulation in retrospective cohort studies, but researchers can directly acquire relevant data on exposure and outcome according to the study design in prospective studies, so the risk of bias is small. Thus, instead of pooling results of Page 17 of 42

BMJ Open

the two studies, we reported them individually. Only one prospective cohort study suggested that regardless of whether SUA was estimated as a continuous or a categorical variable, elevated SUA level was significantly associated with increased risk of all-cause and CV mortality in PD patients. Whereas, there was no significant associations between them in the retrospective studies. Below we have attempted to discuss the inconsistency of the results from the aspects of participants, exposure, comparability and outcomes.

First of all, the prospective cohort study clearly indicated that participants on PD were consecutively enrolled. It is well known that consecutive recruitment is very important to reduce selection bias. While, in some retrospective studies, the process of enrollment was not detailed. The follow-up of the participants was also a prominent issue, including the duration and adequacy of follow-up and the rate of loss to follow-up. In a prospective study, effective measures can be taken to reduce the loss to follow-up rate to avoid bias. The rate of loss to follow-up in a prospective study by Xia X et al. (2016) was only 3.5% [20], but in some retrospective cohorts, the adequacy and lost follow-up rates were not reported.

Second, hyperuricemia in the PD population was the exposure factor of this study. Both prospective and retrospective cohort studies, the definition of hyperuricemia and the categorization for the SUA level was based on the definition provided in each included article. It should be noted that in retrospective multi-center studies, the measurement methods of SUA may not be uniform across centers. This may lead to measurement bias and have a slight impact on results.

Third, control of the most important and other confounding factors is very important for the comparability between the groups. The most important confounding factors included indicators that can reflect the patient's current residual renal function status. Other confounding factors need to be adjusted and should include gender, age, diabetes history, CVD history, Kt/v, use of UA-lowering drugs, and serum albumin. Most of the studies did not adjust for all potential risk factors. For example, the prospective study of Xia X et al. (2016) lacked adjustment for the confounding factor Kt/v [20]. Therefore, we can not exclude the potential impact of these uncontrolled confounding factors. Regarding the outcomes, the definition of all-cause and cardiovascular death was clear. However, the handling of patients transferring to hemodialysis therapy, loss to follow-up, and renal transplantation was different for prospective and retrospective studies. The above information from patients was used as censoring data for survival analysis in the prospective study [20]. Whereas, in some retrospective studies, they were directly excluded from the study [32]. This may affect the results and lead to inconsistencies between the prospective and retrospective studies. Although the risk of bias in the design type of prospective study was relatively small, the interpretation of the results should still be cautious due to the limited quality and quantity of prospective study.

SUA, known for its detrimental effect, is an endothelial toxin and plays a role in
endothelial dysfunction [40]. However, as a powerful free radical scavenger in human
at the same time, SUA may be expected to offer a number of benefits within the CV

Page 19 of 42

BMJ Open

system in PD patients [41,42]. Besides, the problem of protein loss and malnutrition is prominent in PD population [43]. "Malnutrition-inflammation complex syndrome (MICS)" is believed to be the main cause of the high rate of CV atherosclerotic disease and increased mortality and hospitalization in HD patients [44,45]. The underlying mechanism of MICS may also be present in PD patients. As a nutritional marker, SUA might be involved in the MICS axis. Therefore, the relationship between SUA and mortality in PD patients is a complex proposition. Taking into account the feature of SUA itself, we hypothesize that both extremely low and high SUA level may increase the risk of death. In our study, we also would like to explore the dose-response relationship between SUA level and mortality in PD population, but in the end the analysis to explore a dose-response relationship was impossible due to insufficient data. Further investigations are warranted to clarify this relationship and explore the range of SUA concentration associated with the lowest mortality in the PD patients. Moreover, in addition to different study designs, different study location was also one of the main sources of heterogeneity among studies according to the metaregression test. Subgroup analysis results further suggested hyperuricemia was

associated with a high risk of CV death in PD population only in mainland China. As a result, the relationship between SUA level and the risk of death in different regions needs to be explored and verified by prospective studies in future.

Implications further research

Since the results of prospective and retrospective cohort studies were inconsistent, and the different regions seemed to lead to different results, prospective, multicenter, long

term follow-up studies are required in future. It is important to explore the relationship
between SUA level and the risk of death in different regions, as well as to determine
the range of SUA concentrations which can reduce mortality and improve prognosis in
the PD patients.

Additionally, since PD patients often suffer from underlying diseases and complex conditions, adjustment is required for confounding factors to explore the relationship between these factors and prognosis. For the PD population, the following confounding factors should be considered to make the evidence more compelling. Such as: traditional independent risk factors of CV events (age, gender, total lipoprotein cholesterol, low or high density lipoprotein cholesterol, hypertension, diabetes, smoking [46]), history of CV, emotion status, residual renal function, the related parameters of PD, the parameters of nutritional status, use of diuretic and lower UA agents etc.

Comprehensive information should be reported in detail in the study report so that
readers can become more familiar with the details of the study, and can conduct
secondary research to avoid wasting research resources.

413 Study limitations

There were several limitations in this review. Systematic reviews of observational studies can provide a higher level of evidence, but they also have methodological limitations. For example, the included original studies may differ in their design, data collection methods, and definitions of exposure, confounding factors and outcomes. These differences may have a slight influence on the true effect size. Second, in this

BMJ Open

review, the included studies were mainly from Asian populations (only one from Europe), and the generalizability of the results was limited. Third, in spite of many important confounding factors that to be adjusted in the studies, residual and unknown confounding factors can not be entirely excluded. Fourth, the duration of follow up in all studies was less than 5 years. It is difficult to determine long-term impact of elevated SUA level on mortality. Finally, some necessary data was not obtained, and the exploration of dose-response relationship could not be conducted, but will need to be determined in future studies.

Conclusions

The results from the prospective and retrospective cohort studies were inconsistent. Only one prospective cohort study showed that elevated SUA level was significantly associated with increased risk of all-cause and CV mortality in PD patients. Nevertheless, the pooled result of retrospective cohort studies did not appear to indicate a prominent association. So it is necessary to use SUA-lowering agents with caution for PD patients in clinics. International prospective, multicenter, long term follow-up studies are needed in the future to investigate the relationship between SUA level and the risk of death, and to explore the range of SUA concentrations associated with the

436 lowest mortality in the PD patients.

6	565	
7	566	Dear editors,
8 9	567	
9 10		
10	568	Our study was to systematically evaluate the relationship between serum uric acid,
12		
13	560	all-cause and cardiovascular mortality in peritoneal dialysis patients based on the
14	569	an-cause and cardiovascular monanty in peritonear diarysis patients based on the
15		
16	570	observational studies that have been published. As the nature of the study, ethics
17		
18	571	approval is not applicable for this study.
19	571	approval is not applicable for this study.

 MOOSE Checklist—A Proposed Reporting Checklist for Authors, Editors, and Reporting Checklist for Authors, Editors, and Reporting Meta-analyses

 of Observational Studies

5	27,
6 Checklist Item	Answer g
7 Reporting of background should include	18
Problem definition	Page 5, Line 7-98
10 Hypothesis statement	Page 5, Line 98-100
1 Description of study outcome(s)	Page 5, Line 99-100; Page 6, Line 119-125
Type of exposure or intervention used	Page 5, Line ²⁹⁹⁻¹⁰⁰ ; Page 6, Line 113-117
Type of study designs used	Page 5, Line 108
15 Study population	Page 5, Line 38-100; Page5-6, Line 109-112
¹⁶ Reporting of search strategy should include	ade
17 18 Qualifications of searchers (eg, librarians and investigators)	Page 7, Line 136
Search strategy, including time period included in the synthesis and keywords	Page 7, Line 137-139, Page 7-8, Line 146-155
20 Effort to include all available studies, including contact with authors	Page 7, Line 144-146
Databases and registries searched	Page 7, Line 40-143
22 Search software used, name and version, including special features used (eg, explosion)	Page 7-8, Line 146-155
Use of hand searching (eg, reference lists of obtained articles)	Page 7, Line 142-143
List of citations located and those excluded, including justification	Page 6-7, Line 127-134; Page 10, Line 209-216
Method of addressing articles published in languages other than English	Page 7, Line 143-144
27 28 Method of handling abstracts and unpublished studies	Page 7, Line 943-144
Description of any contact with authors	Page 7, Line
³⁰ Reporting of methods should include	
³ Description of relevance or appropriateness of studies assembled for assessing the hypothesis	Page 8, Line 157-165
to be tested	024
Rationale for the selection and coding of data (eg, sound clinical principles or convenience)	Page 8, Line 162-165
³⁵ Documentation of how data were classified and coded (eg, multiple raters, blinding, and	Page 8, Lineត្ថ167-172
³⁶ interrater reliability)	יל ד
Assessment of confounding (eg, comparability of cases and controls in studies where appropriate)	Page 8, Line 168-169; Page 11, Line 223-231
Assessment of study quality, including blinding of quality assessors; stratification or regression	Page 8-10, Lane 174-203
40 on possible predictors of study results	ьу
Assessment of heterogeneity	Page 9-10, Ligne 197-199
43 Description of statistical methods (eg, complete description of fixed or random effects models,	Page 8-10, 🛓 e 174-203
justification of whether the chosen models account for predictors of study results,	
45 dose-response models, or cumulative meta-analysis)-intsufficient detail conservated idelines	s.*html
