ABSTRACT

Objective

To explore the views of parents and clinicians regarding the optimal content, format and delivery of safety netting information for acute childhood illness.

Design

Qualitative study including semi-structured focus groups and interviews.

Setting

First contact care settings; and community centres, children's centres and nurseries, in the East Midlands, UK.

Participants

Twenty-seven parents from a travelling community, Asian British community, and white British community. Sixteen clinicians including ten doctors and six nurses from a general practice surgery, an out of hours service, and two emergency departments (paediatric and combined adult and paediatric).

Results

Participants described a need for safety netting to contain information on signs and symptoms of serious and common illnesses, illness management, and where and when to seek help. Resources should be basic, simple to use and contain simple symbols. A key criterion was professional endorsement of resources. Internet-based information was desired which is reliable, consistent and up-to-date. Participants described a need for different types of information: that which could be delivered during consultations, as well as more general information for parents to access before consulting a healthcare professional. Face-to-face education, written materials and digital media were suggested delivery mechanisms. Audio-visual material was the preferred option for families with low literacy. Participants commonly suggested internet-based and phone-based resources, but the travelling community were less comfortable with these approaches.

Conclusions

A multifaceted and tailored approach to safety netting is needed so that effective resources are available for parents with varying information needs, literacy levels and ability to use information technology. We have identified key aspects of content, quality criteria and delivery mechanisms for safety netting information from the perspectives of both clinicians and parents. Resources should be co-produced with parents and clinicians to ensure they are valued and utilised by both groups.

ARTICLE SUMMARY

Article focus

- Safety netting could reduce misdiagnoses and avoidable mortality in children, and safely reduce re-attendances to healthcare
- Safety netting has been recommended in the management of acutely sick children by NICE, SIGN and other national groups, but there are no set guidelines regarding the optimal content, format or delivery
- We qualitatively explored the views of clinicians and parents regarding the optimal content, format and delivery of safety netting, which is vital for the development of effective resources

Key messages

- A multifaceted approach is needed to safety netting, with information accessible to different groups with varying information needs, literacy levels and competence in using information technology
- This paper highlights key aspects of safety netting resources that were proposed by both parents and clinicians, which should form the basis of development of future resources
- Safety netting resources should be co-produced by parents and clinicians to ensure they meet the needs of both groups and are maximally effective

Strengths and limitations

- Both parents and clinicians participated, and the findings could form the basis of truly co-produced resources
- We included diverse groups of parents with different information needs and abilities, and clinicians from a range of first contact care settings, to ensure the views of different groups were included
- Data were collected and analysed by a team of researchers including clinical and non-clinical, some parents and some not, enabling a deeper understanding

INTRODUCTION

Acute childhood illness is a major contributor to children's presentation to primary care, and to child mortality. Child and young person mortality has fallen in Europe, but child death rates from treatable causes including asthma, pneumonia and meningitis are higher in the UK than elsewhere in Europe, highlighting a need to better manage acutely sick children (1, 2). The vast majority of children have minor, self-limiting illnesses requiring little or no medical intervention, and it is increasingly difficult for clinicians to identify the very few children with serious illnesses, which often have non-specific presentations and clinical features mimicking those of common, non-serious illness (3). Despite the prevalence of life-threatening acute childhood illness being at an all-time low, there has been an increase in children's emergency hospital admissions, many of which are for minor illnesses which could have been managed in the community (4, 5). Safety netting information given to parents during consultations advises them about when and where to seek further help (6). As well as aiming to prevent misdiagnoses and avoidable child mortality, there is evidence that safety netting can reduce re-attendances in febrile children (7, 8).

Safety netting was first described by Neighbour over 20 years ago, who proposed it to be a core component of general practice (9). More recently, safety netting has been recommended in the management of acutely sick children by the National Institute for Health and Care Excellence (NICE) (10), Scottish Intercollegiate Guidelines Network (SIGN) (11), other national groups (2, 12), general practitioners (6, 13) and researchers (14); and has been introduced as a NICE quality standard (15). Despite these recommendations, there are no set guidelines regarding the optimal content, format and delivery of safety netting.

Anxiety and uncertainty surround parents' decisions about when to consult (and re-consult) healthcare professionals during acute childhood illness at home (16, 17). Safety netting could potentially help to reduce these, and provide the more explicit and consistent advice that parents seek (7). However, the most effective components and ways of delivering safety netting have yet to be identified (18, 19), and there is evidence that current safety netting advice may be inadequate. For example a study of 220 feverish children making 570 contacts with urgent care services found that 19% of parents did not recall being given any safety netting advice, and documentation of safety netting advice regarding what to look for was absent in nearly half (43%) of patients' records (8).

As part of the Acutely Sick Kids – Safety Netting Interventions for Families (ASK SNIFF) project, this study aimed to explore the opinions of parents and first contact clinicians regarding the optimal content, format and delivery of safety netting information. This is vital for the development of effective safety netting materials to increase parental confidence, understanding and satisfaction, decrease uncertainty and anxiety, as well as increase timely and appropriate presentation to primary care. Including and combining the opinions of both clinicians and parents mirrors a key principle of the Children and Young People's Health Outcome's Forum, that families must have a voice and be engaged in the development of services (2).

METHODS

We used a qualitative, exploratory approach due to the lack of prior knowledge on the topic. Maximum variation sampling was used to recruit parents from a wide range of communities, and

both doctors and nurses working in different first contact care settings, in the East Midlands, UK. Any parents with at least one child under the age of five years old, and any clinicians treating children under five years of age at first contact, who were able to speak English, were eligible to participate. We conducted focus groups and/or interviews in each parent community and at each first contact care workplace.

Recruitment was coordinated by email or in person using the local Primary Care Research Network, the Comprehensive Local Research Network for clinicians, and community facilitators, health ambassadors and day nursery/children’s centres managers for parents. All participants gave written informed consent. The study was approved by the East Midlands – Nottingham 2 NHS Research Ethics Committee (REC reference 12/EM/0076) and the appropriate research and development offices of each local Trust. Two experienced female researchers (SN, a children’s nurse lecturer and HS, a social scientist) facilitated focus groups and interviews between May-December 2012, which were semi-structured and lasted around an hour. Participants were asked a number of questions about provision of safety netting information (see Table 1), and the facilitators used prompts to elicit further details. One facilitator took notes and gave a verbal summary at the end, asking participants to correct misinterpretations and give further comments. Focus groups and interviews were audio recorded, transcribed verbatim, and anonymised.

Table 1: Topic guide for focus groups and interviews

<i>Parents</i>
What information do you want/need to find when your child becomes sick?
Where would you like to find/be given this information?
In what ways, if any, would you like to see access to information improved?
In what ways, if any, do you think the information provided needs to be improved?
<i>Clinicians</i>
What safety netting information do you think parents of sick young children should be given?
How do you think they should be given this information?
In what ways, if any, do you feel the safety netting information available needs to be improved?
In what ways, if any, would you like to see access to information improved?

Data were analysed using a grounded theory approach. Separate coding schemes were devised for parent and clinician data, according to the content of focus groups/interviews, and they were edited as data collection and analysis progressed. The coding schemes were developed by CJ (a non-clinical researcher) and SN (a children’s nurse lecturer), who allocated text to codes accordingly. Emerging themes, and comparisons between parent and clinician data, were discussed and developed amongst the wider research team.

RESULTS

Participants

Participants included 27 parents and 16 clinicians. Parents were from a travelling community (recruited via a community facilitator), an Asian British community (recruited at a local community centre and a children’s centre), and the white British community (recruited from a children’s centre and a private nursery) (see Table 2). Clinicians were included from a general practice surgery, a

District General Hospital (DGH) emergency department (ED) (treating adults and children), a paediatric ED and an out-of-hours service (OOHS) (see Table 3).

Table 2: Characteristics of participating parents

Characteristics of parents		Number of parents
Community	Travelling families	6
	Asian British	11
	White	10
Gender	Female	24
	Male	3
Age	under 20 years	1
	20-29 years	5
	30-39 years	16
	40-49 years	5
Adults in the household	Single parent household	5

Below we present the main themes emerging from the data regarding parents' and clinicians' desires for safety netting, under the categories of content, quality criteria and delivery.

Safety netting content

There was consensus among clinicians working in different settings that paediatric illness is broad, and safety netting advice should focus on signs and symptoms of the most serious and most common childhood illnesses: *"It's the nasty ones that you want to catch and the very common things that people will have never seen before but are OK"* (DGH ED doctor). Some clinicians thought that in addition to specific advice, there is a need for generic advice: *"perhaps there could be... more kind of generic advice about unwell children"* (OOHS GP). This emphasises the potential need for two different resources: a diagnosis-related safety netting resource for use during/post-consultation, and a more general educational resource for use pre-consultation.

Clinicians described the importance of signposting parents to different services according to illness severity, and providing information on illness management. Primary care staff focused on the need to educate parents about when to care for their child at home or visit the pharmacy, whereas ED staff focused more on the need to communicate what signs and symptoms indicate that parents should attend an ED immediately.

Parents described a need for similar information, namely when to worry, and what symptoms are associated with the most common and most serious illnesses (particularly meningitis). After receiving a diagnosis, information is wanted on illness causation, management and trajectory: *"Where I ask every question under the sun. What is it, why did they get that, how many times will they get it again?"* (travelling community mother). When and where to access help was another key component of content: *"Is it phone, such and such, is it take to A&E, you know, is it wait till the morning, see how it is?"* (white British mother).

Safety netting quality criteria

Clinicians and parents alike stated that safety netting resources should be basic, simple to use, with simple messages. Simple symbols and colour indicators were suggested for presenting safety netting information visually, which would be particularly useful for people who are unable to easily understand written information. Suggestions included ticks and crosses, sad and happy faces, traffic lights, red and green: *"a picture with a green smiley face, a meningococcal septicaemia rash with a big upset blue light on top of it type face or something like that"* (DGH ED doctor). Both parents and clinicians felt that information should be provided in simple language, as well as multiple languages; and that it should be symptoms-based because parents would not always know their child's diagnosis when searching for information.

Importantly, it was commented that written information, including internet-based resources, should be easy and quick to access: *"I think it's just being able to access information very quickly..."* (white British mother). However one clinician raised a caveat: *"you've got to be very careful with the information that you are putting out there, because you don't want to drive the paranoia more that there is"* (paediatric ED doctor).

A key quality criterion identified by parents and clinicians was professional endorsement: *"I think if it was NHS backed you'd kind of have a bit more trust"* (white British mother). Publicity was also highlighted: *"it needs to be publicised that patients know to access that site, whereas what's happening now is that they're accessing Google and getting a whole lot of symptoms which, y'know, lots of them are not necessarily useful and, erm, heightens the anxiety"* (GP surgery doctor). These criteria were described particularly in relation to internet-based safety netting resources: currently,

searching the internet generates an 'overload' of information, some of which is not useful, which creates uncertainty and anxiety amongst parents. Access to reliable, consistent, up-to-date internet-based information was commonly requested: *"the problem is I think the information's there, it's not all in one place, it's all over different websites and if the Department of Health was able to somehow streamline the advice nationally and set up a process of okaying national advice for parents... I think that would be the way to do it"* (paediatric ED doctor).

It was suggested that parents need resources which are portable, particularly when caring for a distressed child. Different methods were suggested for achieving this, including providing portable hard copy: *"You've got them clung to you cause they're unwell, you're not going to sit at a computer"* (GP surgery nurse); *"I think they sort of produce sort of credit card sized things they can give out... so perhaps more of those sorts of resources"* (OOHS GP). Alternatively, phone-based internet access could provide quick and easy access to information: *"I would do it on my phone, oh yeah, yeah, yeah, very much so. And that I actually find easier than picking up the phone because if you've got a crying child, trying to pick up the phone and talk to somebody is actually a lot more difficult than having a quick look on the internet to see..."* (white British mother).

Delivery of safety netting

As described above, participants described a need for different types of safety netting resources including those delivered during consultations, and those accessed prior to consultation.

Consultation-based safety netting

Clinicians described how both verbal and written safety netting information could be delivered during consultations, and suggested demonstration of physical signs including tracheal tug, intercostal recession, slow capillary refill time: *"simple things like tracheal recession that are quite easy to demonstrate... just to show them if they come in with that presenting complaint and it's just talking through it isn't it, if you see any of these signs then you need to come straight back then"* (DGH ED nurse).

Another type of safety netting was referring children to other services such as community children's nurses. Some clinicians thought that written safety netting materials should be tailored to the local area accordingly: *"a bit more specific to the area as well, that would be good so it was, you know it takes into account sort of local pathways, what's available locally including things like the community children's nurses"* (OOHS GP). Conversely, one parent also highlighted the need for standardised advice: *"It should be across nationally and so on, so that everyone is getting the same message"* (Asian British mother).

Pre-consultation education

Safety netting resources for use prior to consultation included general preparatory education to be accessed prior to illness occurring; and more specific information for parents to access during acute childhood illness, before they consult a healthcare professional.

Educational methods suggested by clinicians included education by health visitors, and peer education so that parents can learn from the experiences of others – a caveat being that the information is correct: *"actually learning by somebody else's experience what happened and what*

1
2
3 were you told and it's getting that because peer education, if it's correct, 'cause that's another
4 reason why we get to see people, 'cause another relative has sent them in and said you must be seen,
5 because advice has changed..." (GP surgery nurse). Other suggestions were delivery by
6 school/nursery teachers and social workers. Parents also suggested education on childhood illnesses
7 by health visitors, schools/nurseries, as well as libraries, community centres, and GP surgeries (in
8 waiting rooms as well as during consultations). They also suggested community based delivery
9 systems including community champions, community educational programmes (such as short
10 courses in community centres), and community snowballing (whereby healthcare professionals
11 provide initial educational sessions, then peers provide these sessions afterwards).
12
13

14
15 Written materials were suggested for educating parents prior to their child becoming ill: "they used
16 to have a big resuscitation poster that they advised you to put in your child's bedroom... you could
17 have your symptoms checker thing on there because you're more likely to read it at the time you
18 don't need it, than the time you do need it" (DGH ED nurse). Both parents and clinicians mentioned
19 posters, and suggested the information pack for new parents as a way to deliver written information
20 (although parents did comment that they did not use the information provided in this pack beyond
21 the neonatal period). Other parental suggestions for written materials included booklets, leaflets,
22 flash cards, and small quizzes. Both parents and GPs had limited knowledge of the information on
23 childhood illness currently contained in the personal child health record ("red book"), and felt that it
24 was not well-used by parents or GPs; hence building on the information contained there may not be
25 an effective mechanism to educate parents about childhood illness.
26
27

28
29 Parents suggested a wide range of digital media which could be used to deliver information,
30 including internet, phone-based media, DVD, television programmes, and rolling displays on waiting
31 room screens. Many parents recalled media campaigns for stroke, and the glass test for non-
32 blanching rash in meningitis. These campaigns appear to have reached all of the social groups in the
33 sample. Parents felt that media campaigns could be successful for acute childhood illness. The GP
34 surgery focus group acknowledged the success of media campaigns and suggested this could work
35 for educating parents on child illness; although it was acknowledged that media campaigns could
36 create anxiety.
37
38

39
40 Internet-based resources

41
42 Internet-based resources such as a centralised website were commonly mentioned by parents and
43 clinicians alike. One resource parents would like is a well-signposted website with NHS endorsement,
44 which is easy to search and appropriate for mobile phones. Parents were in favour of doctors giving
45 out information about a reliable site at the end of consultations. Clinicians indicated they were
46 happy to do this; but it would need to be simple to use: "you wouldn't want to, yeah, be getting into
47 huge conversations about how you do it... how you access it, so yeah, it would need to be sufficiently
48 simple and accessible" (OOHS GP).
49
50

51
52 Similarly to parents, clinicians in all settings suggested that a phone-based app could be successful in
53 helping parents of sick children assess whether/where to seek help: "World and times are changing,
54 everything is about internet, everything is about apps and I think if you've got something well written
55 and accessible, on the internet with maybe an iPhone app, an android app, that people can download
56 y'know, some sick kids guide or something like that with a bit of a symptom checker and robust, this
57 is what paediatricians, this is what GP's, this is what emergency physicians would advise you to do,
58
59
60

then I think people will take that seriously, and I suspect it would cut down the attendance rate at all different places plus make people a lot more happy" (DGH ED doctor). However, the travelling community highlighted that the current generation of parents are often unfamiliar with information technology: "But the new generation when they get a bit older, in a couple of years from now, cause all the children now they're all permanently at school that would help them but not for all us, not for this generation" (travelling community mother).

Audiovisual material

A benefit of internet-based resources, highlighted by parents and clinicians, is that they could include short video clips showing signs and symptoms, presenting information that is difficult to explain verbally or in diagrams: "some kind of videos of things that you kind of click on to see what it, or pictures to see what it looks like. Because they're saying you're breathing faster, but as I said, that's one thing for one person and you know, it might mean something else to somebody else. And give patients and parents that autonomy to say actually no, I've looked at this, this is what it looks like and therefore my child is breathing fast" (paediatric ED doctor). Parents suggested clips of sounds of specific coughs (croup, whooping cough), respiratory movements (recession) or the appearance of different rashes (chickenpox, meningitis). Conditions that were suggested for video format by clinicians, some of which matched those suggested by parents, were croup, wheeze, increased work of breathing, recession, bronchiolitis, dehydrated child, floppy child, seizures and fainting, tracheal tug, capillary refill time, and rashes. Parents highlighted that these could be viewed, for example, on a mobile phone whilst holding a baby. Audiovisual material was the preferred option for families with low literacy: the Asian British and travelling communities highlighted that some families would not be able to read written language. Limitations of audiovisual material were however recognised: "[Doctor 1] Photos are very difficult because even if you look at the different atlases we have for dermatology... [Doctor 2] and each book looks slightly different [Doctor 3] And it can be falsely reassuring can't it. 'Cause you have meningococcal disease, you can have a blanching rash" (paediatric ED doctors).

DISCUSSION

Principle findings and implications

Co-production

Parents and clinicians described a diverse range of desirable attributes for safety netting advice, as well as techniques for its delivery. This highlights the need for true co-production of safety netting resources by both parents and clinicians, throughout every stage of design and development of resources, to ensure that they meet the range of criteria identified as important by both groups. This mirrors the key principle of the Children and Young People's Health Outcome's Forum regarding family involvement in the development of services (2). Safety netting is a perfect example of where true co-production by clinicians and parents could result in development of effective resources which will be utilized and valued by both groups. There was a great deal of correlation between the themes emerging from the two groups, which highlights the potential for the development of safety netting techniques which are indeed endorsed by both parents and clinicians. Figure 1 shows desirable safety netting attributes that were proposed by both parents and clinicians: resources should be developed that meet these criteria.

Multifaceted approach

Participants recognized that one approach will not be appropriate for all parents, and that a variety of techniques and resources is needed. For example, written materials are not suitable for those with low literacy or English language; and websites are not suitable for those who lack confidence in, or access to, the internet and smart phones. There may be a need for a tailored approach to meet individual needs.

An information leaflet for parents on feverish illness has already been developed by NICE; yet it is not multifaceted or tailored for different groups, which is perhaps the reason why none of the clinicians reported using the leaflet for safety netting. Our study highlights the need for multifaceted, tailored approaches co-produced with parents.

Delivery

Participants were imaginative in their consideration of how safety netting advice could be delivered; ideas included DVDs, television programmes, rolling displays in waiting rooms, posters, booklets, leaflets, flashcards and even quizzes. Media campaigns were thought to have been successful at improving knowledge in other areas of health, and could be applied to childhood illness; however, clinicians warned against creating anxiety. Furthermore, it would be difficult to design and deliver a successful media campaign for such a broad topic as acute childhood illness. Clinicians also warned against falsely reassuring parents; for example emphasizing a non-blanching rash in pictures may prevent children with meningococcal disease being presented before the appearance of this symptom. There is a balance to be met between creating false reassurance and over-anxiety (3).

Types of information

It was commonly suggested by both parents and clinicians that there is a need for different types of information to be delivered at different times:

- 1. Specific information: provided when children are sick (usually during a consultation), specific to the particular illness the child is experiencing
- 2. Symptom related information: accessible by parents pre-consultation when their children are sick, could also be provided during a consultation
- 3. General information: education for parents on childhood illness in general

Regarding specific illness- or symptom-related information, a common proposal was for a well-signposted website on childhood illness, with professional endorsement, that is easy for parents to search, and provides the information they need when their child is sick. It was also frequently suggested that this should be compatible for use on mobile phones so that parents can access it easily whilst caring for their child. The inclusion of pictures and videos would increase accessibility. A variety of symbols were suggested which could be used in such resources including sad and happy faces, and different coloured symbols. Regarding general information, both groups suggested that education could be delivered by health visitors, or by peers in the community; with the important caveat of ensuring that the information delivered is correct.

Strengths and limitations

This study has taken a first step at identifying the optimal content, format and delivery of information resources for parents of acutely sick young children, from the perspectives of parents and clinicians. Including both parents and clinicians strengthened our study because in order to be effective, resources must be endorsed and valued by both groups. Indeed we identified similar needs from both groups, indicating the possibility of developing resources which are co-produced. Furthermore, we included diverse groups of parents with different literacy levels, information needs, and ability to use information technology, ensuring that the views of different groups with diverse needs are understood. A range of doctors and nurses from different settings were also included, allowing us to include the perspectives of the broad group of clinicians who provide safety netting advice in different settings. However whilst the maximum variation sampling provided us with participants with a diverse range of characteristics, the extent to which the findings are generalizable to others in the same or different groups and geographical locations is not known. Data were collected and analysed by a team of researchers with different backgrounds, so their range of perspectives helped to reduce bias and facilitated a deeper understanding.

Conclusion

A multifaceted and tailored approach to safety netting is needed, in which information is delivered in multiple ways and is accessible to different groups of parents with varying needs, resources and abilities. It is important that resources are co-produced with both parents and clinicians so that they are accessible and understood by parents, as well as endorsed by clinicians. This study has shown that it is possible to identify common priorities amongst both groups regarding resource development.

Research is needed into the effectiveness of different components of safety netting resources and the impact on parent knowledge, understanding, satisfaction, anxiety and re-consultation rates, amongst other outcomes. There is also a need for the development of safety netting quality standards to ensure that all clinicians provide parents with appropriate advice, and so that all parents receive the correct information in an efficient way. This study is a first step towards developing testable safety netting interventions and developing an evidence base around safety netting on which to base quality standards.

Authors' contributions

The study was conceptualized and designed by SN, ML, DR and MT. The data were collected by SN and HS, and analyzed by CJ and SN. CJ drafted the paper; all authors read and approved the final version.

Acknowledgments

We thank the participants for taking part, and all those who coordinated recruitment.

Competing interests

ML was clinical director leading development for the NICE feverish illness guidelines, was a NICE fellow from 2010-2013, and is on the NHS evidence advisory board. The other authors have no competing interests to declare.

Funding

This publication presents independent research funded by the National Institute for Health Research (NIHR) under its Programme Grants for Applied Research funding scheme (RP-PG-0407-10347) and arising from a Career Development Fellowship supported by the NIHR (MT). The views expressed in this publication are those of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health.

ABSTRACT**Objective**

To explore the views of parents and clinicians regarding the optimal content, format and delivery of safety netting information for acute childhood illness.

Design

Qualitative study including semi-structured focus groups and interviews.

Setting

First contact care settings, and community centres, children's centres and nurseries, in the East Midlands, UK.

Participants

Twenty-seven parents from a travelling community, Asian British community, and white British community. Sixteen clinicians including ten doctors and six nurses from a general practice surgery, an out of hours service, and two emergency departments (paediatric and combined adult and paediatric).

Results

Participants described a need for safety netting to contain information on signs and symptoms of serious and common illnesses, illness management, and where and when to seek help. Resources should be basic, simple to use and contain simple symbols. A key criterion was professional endorsement of resources. Internet-based information was desired which is reliable, consistent and up-to-date. Participants described a need for different types of information: that which could be delivered during consultations, as well as more general information for parents to access before consulting a healthcare professional. Face-to-face education, written materials and digital media were suggested delivery mechanisms. Audio-visual material was preferred by families with low literacy. Participants commonly suggested internet-based and phone-based resources, but the travelling community were less comfortable with these approaches.

Conclusions

A multifaceted and tailored approach to safety netting is needed so that effective resources are available for parents with varying information needs, literacy levels and ability to use information technology. We have identified key aspects of content, quality criteria, format and delivery mechanisms for safety netting information from the perspectives of both clinicians and parents. Resources should be co-produced with parents and clinicians to ensure they are valued and utilised by both groups.

ARTICLE SUMMARY

Article focus

- Safety netting could reduce misdiagnoses and avoidable mortality in children, and safely reduce re-attendances to healthcare
- Safety netting has been recommended in the management of acutely sick children by NICE, SIGN and other national groups, but there are no set guidelines regarding the optimal content, format or delivery
- We qualitatively explored the views of clinicians and parents regarding the optimal content, format and delivery of safety netting, which is vital for the development of effective resources

Key messages

- A multifaceted approach is needed to safety netting, with information accessible to different groups with varying information needs, literacy levels and competence in using information technology
- This paper highlights key aspects of safety netting resources that were proposed by both parents and clinicians, which should form the basis of development of future resources
- Safety netting resources should be co-produced by parents and clinicians to ensure they meet the needs of both groups and are maximally effective

Strengths and limitations

- Both parents and clinicians participated, and the findings could form the basis of truly co-produced resources
- We included diverse groups of parents with different information needs and abilities, and clinicians from a range of first contact care settings, to ensure the views of different groups were included; however, the extent to which the findings are generalizable to other groups or populations is not known
- Data were collected and analysed by a team of researchers including clinical and non-clinical, some parents and some not, enabling a deeper understanding

INTRODUCTION

Acute childhood illness is a major contributor to children's presentation to primary care, and to child mortality. Child and young person mortality has fallen in Europe, but child death rates from treatable causes including asthma, pneumonia and meningitis are higher in the UK than elsewhere in Europe, highlighting a need to better manage acutely sick children (1, 2). The vast majority of children have minor, self-limiting illnesses requiring little or no medical intervention, and it is increasingly difficult for clinicians to identify the very few children with serious illnesses, which often have non-specific presentations and clinical features mimicking those of common, non-serious illness (3). Despite the prevalence of life-threatening acute childhood illness being at an all-time low, there has been an increase in children's emergency hospital admissions, many of which are for minor illnesses which could have been managed in the community (4, 5). Safety netting information given to parents during consultations advises them about when and where to seek further help (6). As well as aiming to prevent misdiagnoses and avoidable child mortality, there is evidence that safety netting can reduce re-attendances in febrile children (7, 8).

Safety netting was first described by Neighbour over 20 years ago, who proposed it to be a core component of general practice (9). More recently, safety netting has been recommended in the management of acutely sick children by the National Institute for Health and Care Excellence (NICE) (10), Scottish Intercollegiate Guidelines Network (SIGN) (11), other national groups (2, 12), general practitioners (6, 13) and researchers (14); and has been introduced as a NICE quality standard (15). Despite these recommendations, there are no set guidelines regarding the optimal content, format and delivery of safety netting.

Anxiety and uncertainty surround parents' decisions about when to consult (and re-consult) healthcare professionals during acute childhood illness at home (16, 17). Safety netting could potentially help to reduce these, and provide the more explicit and consistent advice that parents seek (7). However, the most effective components and ways of delivering safety netting have yet to be identified (18, 19), and there is evidence that current safety netting advice may be inadequate. For example a study of 220 feverish children making 570 contacts with urgent care services found that 19% of parents did not recall being given any safety netting advice, and documentation of safety netting advice regarding what to look for was absent in nearly half (43%) of patients' records (8).

As part of the Acutely Sick Kids – Safety Netting Interventions for Families (ASK SNIFF) project, this study aimed to explore the opinions of parents and first contact clinicians regarding the optimal content, quality criteria, format and delivery of safety netting information. This is vital for the development of effective safety netting materials to increase parental confidence, understanding and satisfaction, decrease uncertainty and anxiety, as well as increase timely and appropriate presentation to primary care. Including and combining the opinions of both clinicians and parents mirrors a key principle of the Children and Young People's Health Outcome's Forum, that families must have a voice and be engaged in the development of services (2).

We used a qualitative, exploratory approach due to the lack of prior knowledge on the topic. Maximum variation sampling was used to recruit parents from a wide range of communities, and both doctors and nurses working in different first contact care settings, in the East Midlands, UK. Any parents with at least one child under the age of five years, and any clinicians treating children under five years of age at first contact, who were able to speak English, were eligible to participate. We conducted focus groups and/or interviews in each parent community and at each first contact care workplace.

Recruitment was coordinated by email or in person using the local Primary Care Research Network, the Comprehensive Local Research Network for clinicians, and community facilitators, health ambassadors and day nursery/children’s centre managers for parents. All participants gave written informed consent. The study was approved by the East Midlands – Nottingham 2 NHS Research Ethics Committee (REC reference 12/EM/0076) and the appropriate research and development offices of each local Trust. Two experienced female researchers (SN, a children’s nurse lecturer and HS, a social scientist) facilitated focus groups and interviews between May-December 2012, which were semi-structured and lasted around an hour. Participants were asked a number of questions about provision of safety netting information (see Table 1), and the facilitators used prompts to elicit further details. One facilitator took notes and gave a verbal summary at the end, asking participants to correct misinterpretations and give further comments. Focus groups and interviews were audio recorded, transcribed verbatim, and anonymised.

Table 1: Topic guide for focus groups and interviews

<i>Parents</i>
What information do you want/need to find when your child becomes sick?
Where would you like to find/be given this information?
In what ways, if any, would you like to see access to information improved?
In what ways, if any, do you think the information provided needs to be improved?
<i>Clinicians</i>
What safety netting information do you think parents of sick young children should be given?
How do you think they should be given this information?
In what ways, if any, do you feel the safety netting information available needs to be improved?
In what ways, if any, would you like to see access to information improved?

Data were analysed using the grounded theory method of constant comparison. Three main themes were pre-determined by the research question and topic guide (content, quality criteria, and format/delivery of safety netting). Codes and subthemes within each of these themes were developed according to the content of focus groups/interviews. Separate coding schemes were devised for parent and clinician data, with many of the codes occurring in both the parent and clinician coding schemes. Throughout the process of data collection and analysis, codes were edited, combined and new ones added, and codes were grouped together as subthemes were developed within each theme. The coding schemes were developed together by CJ (a non-clinical researcher) and SN (a children’s nurse lecturer), who allocated text to codes accordingly. CJ coded the clinician data and SN coded the parent data, and each researcher checked the other’s coding. Both researchers were familiar with the content of all focus groups/interviews, and both coding

schemes. Emerging subthemes, and comparisons between parent and clinician data, were discussed and developed amongst the wider research team. The constant comparative method enabled us to identify similarities and differences within the data coded to the same and different subthemes from parents and clinicians.

RESULTS

Participants

Participants included 27 parents and 16 clinicians. Parents were from a travelling community (recruited via a community facilitator), Asian British community (recruited at a local community centre and a children's centre), and white British community (recruited from a children's centre and a private nursery) (see Table 2). Clinicians were included from a general practice surgery, a District General Hospital (DGH) emergency department (ED) (treating adults and children), a paediatric ED and an out-of-hours service (OOHS) (see Table 3).

Below we present the three main themes – content, quality criteria and format/delivery of safety netting – and the subthemes within them. Tables 4, 5 and 6 display each theme respectively and the subthemes within them, with quotes to illustrate aspects of our interpretation of the data within each of the subthemes.

Safety netting content

There was consensus among clinicians working in the different settings that paediatric illness is broad, and safety netting advice should focus on signs and symptoms of the most serious and most common childhood illnesses: *“It’s the nasty ones that you want to catch and the very common things that people will have never seen before but are OK”* (DGH ED doctor). Some clinicians thought that in addition to specific advice given during consultations, there is a need for generic advice or education: *“perhaps there could be... more kind of generic advice about unwell children”* (OOHS GP); *“instant access [to information] doesn’t really help because you need to build up your knowledge long before the child becomes ill”* (regular ED doctor). This emphasises the potential need for two different resources: a diagnosis or illness-related safety netting resource for use during/post-consultation, and a more general educational resource for use pre-consultation.

Clinicians described the importance of signposting parents to different services according to illness severity, and providing information on illness management. Primary care staff focused on the need to educate parents about when to care for their child at home or visit the pharmacy, whereas ED staff focused more on the need to communicate what signs and symptoms indicate that parents should attend an ED immediately.

Parents’ needs for information matched those of clinicians,, namely what symptoms are associated with the most common and most serious illnesses (particularly meningitis), and when/where to access help. After receiving a diagnosis, information is wanted on illness causation, management and trajectory: *“Where I ask every question under the sun. What is it, why did they get that, how many times will they get it again?”* (travelling community mother).

Table 4: Subthemes and illustrative quotes within the Safety Netting Content theme

Subtheme	Illustrative quote
Most serious and most common childhood illnesses	<i>I don’t think it’s going to be possible to inform everybody about every kind of conditions that are out there, but there may be some that we can consider the common ones and more serious ones, you know</i> Asian British father

Signposting to different services	<i>Is it phone, such and such, is it take to A&E, you know, is it wait till the morning, see how it is?</i>	White British mother
-----------------------------------	---	----------------------

205 Safety netting quality criteria

206 Clinicians and parents alike stated that safety netting resources should be basic, simple to use, with
 207 simple messages. Simple symbols and colour indicators were suggested for presenting safety netting
 208 information visually, which would be particularly useful for people who are unable to easily
 209 understand written information. Suggestions included ticks and crosses, sad and happy faces, traffic
 210 lights, red and green: *"a picture with a green smiley face, a meningococcal septicaemia rash with a
 211 big upset blue light on top of it type face or something like that"* (DGH ED doctor). Both parents and
 212 clinicians felt that information should be provided in simple language, as well as multiple languages;
 213 and that it should be symptoms-based because parents would not always know their child's
 214 diagnosis when searching for information.

215 Importantly, it was commented that written information, including internet-based resources, should
 216 be easy and quick to access. However one clinician raised a caveat: *"you've got to be very careful
 217 with the information that you are putting out there, because you don't want to drive the paranoia
 218 more that there is"* (paediatric ED doctor).

219 A key quality criterion identified by both parents and clinicians was professional endorsement: *"I
 220 think if it was NHS backed you'd kind of have a bit more trust"* (white British mother). Publicity was
 221 also highlighted: *"it needs to be publicised that patients know to access that site, whereas what's
 222 happening now is that they're accessing Google and getting a whole lot of symptoms which, y'know,
 223 lots of them are not necessarily useful and, erm, heightens the anxiety"* (GP surgery doctor). These
 224 criteria were described particularly in relation to internet-based safety netting resources: currently,
 225 searching the internet generates an 'overload' of information, some of which is not useful, which
 226 creates uncertainty and anxiety amongst parents. Access to reliable, consistent, up-to-date internet-
 227 based information was commonly requested: *"the problem is I think the information's there, it's not
 228 all in one place, it's all over different websites and if the Department of Health was able to somehow
 229 streamline the advice nationally and set up a process of okaying national advice for parents... I think
 230 that would be the way to do it"* (paediatric ED doctor).

231 It was suggested that parents need resources which are portable, particularly when caring for a
 232 distressed child. Different methods were suggested for achieving this, including providing portable
 233 hard copy: *"You've got them clung to you cause they're unwell, you're not going to sit at a computer"*
 234 (GP surgery nurse); *"I think they sort of produce sort of credit card sized things they can give out... so
 235 perhaps more of those sorts of resources"* (OOHS GP). Alternatively, phone-based internet access
 236 could provide quick and easy access to information: *"I would do it on my phone, oh yeah, yeah, yeah,
 237 very much so. And that I actually find easier than picking up the phone because if you've got a crying
 238 child, trying to pick up the phone and talk to somebody is actually a lot more difficult than having a
 239 quick look on the internet to see..."* (white British mother).

240 Table 5: Subthemes and illustrative quotes within the Safety Netting Quality Criteria theme

Subtheme	Illustrative quote
----------	--------------------

Basic	<i>It needs to be absolute almost so simple basic</i>	GP surgery doctor
Simple symbols, colours	<i>Simple visual things like a tick and a cross. Lots of people know that a cross is not a good thing or it's a danger. Anything in red, anything green is good... or a sad face or a happy face</i>	Asian British mother
Multiple languages	<i>The information that comes out actually needs to be in multiple languages as well</i>	Regular ED doctor
Symptoms-based	<i>of course a lot of the time you don't know the diagnosis so, yeah, so it's important it isn't sort of restricted to a diagnosis really I think.</i>	OOHS GP
Professional endorsement	<i>Obviously it has to be audited and have involvement with the government.</i>	Asian British mother
Publicised	<i>half of it would be the media in letting the parents know that is out there, because half of these things you don't know that they exist and you don't know what to trust.</i>	white British mother
Easy and quick to access	<i>I think it's just being able to access information very quickly</i>	white British mother
Portable	<i>Nothing that adds to your weight of your bag</i>	white British mother
	<i>I always tend to keep a lot of stuff like that in her bag so I always know where it is and if I'm with her, her bag's always around anyway, so I would prefer that.</i>	white British mother

Format and delivery of safety netting

As described above, participants described a need for different types of safety netting resources including those delivered during consultations, and those accessed prior to consultation. They also acknowledged that information should be provided in multiple formats: *"It can be on different forms of media, Internet. Obviously, Internet may not be accessible to many people and if it is accessible, they may not be able to go to the right information, right section so having it in different formats will be quite helpful."* (Asian British father).

Consultation-based safety netting

Clinicians described how both verbal and written safety netting information could be delivered during consultations, and suggested demonstration of physical signs including tracheal tug, intercostal recession, and slow capillary refill time. Provision of written materials during consultations could be useful for parents: *"Well half the time when you're taking your child to the doctors they're not very well, are they, so they're clingy, you've had to probably strip them off... so they're crying and they're trying to tell you all this information and getting them back dressed again really quickly... There is pressure to get out quickly, I think, so I think you do forget what the doctor has said."* (white British mother).

Another type of safety netting was referring children to other services such as community children's nurses. Some clinicians thought that written safety netting materials should be tailored to the local area accordingly: *"a bit more specific to the area as well, that would be good so it was, you know it takes into account sort of local pathways, what's available locally including things like the*

community children's nurses" (OOHS GP). Conversely, one parent highlighted the need for standardised advice: *"It should be across nationally and so on, so that everyone is getting the same message"* (Asian British mother).

Pre-consultation education

Safety netting resources for use prior to consultation included general preparatory educational information to be accessed prior to illness occurring; and more specific information for parents to access during acute childhood illness, before they consult a healthcare professional.

Educational methods suggested by clinicians included education by health visitors, and peer education so that parents can learn from the experiences of others – a caveat being that the information is correct: *"actually learning by somebody else's experience what happened and what were you told and it's getting that because peer education, if it's correct, 'cause that's another reason why we get to see people, 'cause another relative has sent them in and said you must be seen, because advice has changed..."* (GP surgery nurse). Other suggestions were delivery by school/nursery teachers and social workers. Parents had similar suggestions to clinicians, namely education on childhood illnesses by health visitors and schools/nurseries; as well as novel suggestions including libraries, community centres, and GP surgeries (in waiting rooms as well as during consultations). They also suggested community based delivery systems including community champions, community educational programmes (such as short courses in community centres), and community snowballing (whereby healthcare professionals provide initial educational sessions, then peers provide these sessions afterwards).

Written materials were suggested for educating parents prior to their child becoming ill.. Both parents and clinicians mentioned posters, and suggested the information pack for new parents as a way to deliver written information (although parents did comment that they did not use the information provided in this pack beyond the neonatal period). Other parental suggestions for written materials included booklets, leaflets, flash cards, and small quizzes. Both parents and GPs had limited knowledge of the information on childhood illness currently contained in the personal child health record ("red book"), and felt that it was not well-used by parents or GPs; hence building on the information contained there, or introducing new books, may not be an effective mechanism to educate parents about childhood illness: *"I think I possibly looked at it when I was a new mum with you know, so much enthusiasm, and then about a week in I was like... I'm far too tired to do this, there's no way I'm reading through that book"* (white British mother).

Parents suggested a wide range of digital media which could be used to deliver information, including internet, phone-based media, DVD, television programmes, and rolling displays on waiting room screens. Many parents recalled media campaigns for stroke, and the glass test for non-blanching rash in meningitis. These campaigns appear to have reached all of the social groups in the sample. Parents felt that media campaigns could be successful for acute childhood illness. The GP surgery focus group acknowledged the success of media campaigns and suggested this could work for educating parents on child illness; although it was acknowledged that media campaigns could create anxiety.

Internet-based resources such as a centralised website were commonly mentioned by parents and clinicians alike. One resource parents would like is a well-signposted website with NHS endorsement, which is easy to search and appropriate for mobile phones. Parents were in favour of doctors giving out information about a reliable site at the end of consultations. Clinicians indicated they were happy to do this; but it would need to be simple to use: *“you wouldn’t want to, yeah, be getting into huge conversations about how you do it... how you access it, so yeah, it would need to be sufficiently simple and accessible”* (OOHS GP).

Similarly to parents, clinicians in all settings suggested that a phone-based app could be successful in helping parents of sick children assess whether/where to seek help: *“World and times are changing, everything is about internet, everything is about apps and I think if you’ve got something well written and accessible, on the internet with maybe an iPhone app, an android app, that people can download y’know, some sick kids guide or something like that with a bit of a symptom checker and robust, this is what paediatricians, this is what GP’s, this is what emergency physicians would advise you to do, then I think people will take that seriously, and I suspect it would cut down the attendance rate at all different places plus make people a lot more happy”* (DGH ED doctor). However, the travelling community highlighted that the current generation of parents are often unfamiliar with information technology: *“But the new generation when they get a bit older, in a couple of years from now, cause all the children now they’re all permanently at school that would help them but not for all us, not for this generation”* (travelling community mother).

Audiovisual material

A benefit of internet-based resources, highlighted by parents and clinicians, is that they could include short video clips showing signs and symptoms, presenting information that is difficult to explain verbally or in diagrams. Parents suggested clips of sounds of specific coughs (croup, whooping cough), respiratory movements (recession) or the appearance of different rashes (chickenpox, meningitis). Conditions that were suggested for video format by clinicians, some of which matched those suggested by parents, were croup, wheeze, increased work of breathing, recession, bronchiolitis, dehydrated child, floppy child, seizures and fainting, tracheal tug, capillary refill time, and rashes. Parents highlighted that these could be viewed, for example, on a mobile phone whilst holding a baby. Audiovisual material was the preferred option for families with low literacy: the Asian British and travelling communities highlighted that some families would not be able to read written language. Limitations of audiovisual material were however recognised: *“[Doctor 1] Photos are very difficult because even if you look at the different atlases we have for dermatology... [Doctor 2] and each book looks slightly different [Doctor 3] And it can be falsely reassuring can’t it. ‘Cause you have meningococcal disease, you can have a blanching rash”* (paediatric ED doctors).

340 **Table 6: Subthemes and illustrative quotes within the Format and Delivery of Safety Netting theme**

Subtheme		Illustrative quote	
Consultation-based	Signs and symptoms to look for	<i>simple things like tracheal recession that are quite easy to demonstrate... just to show them if they come in with that presenting complaint and it's just talking through it isn't it, if you see any of these signs then you need to come straight back then</i>	DGH ED nurse
	Information sheets	<i>My doctor did give like an information leaflet... and I did read through it, because like on the Internet, you can get into so many areas and then you know you think, you need to feed your son, but when you've got a sheet at least you can find time to do that</i>	Asian British mother
Pre-consultation education	Health visitors	<i>I think the information almost needs to come before your child's ill at health visitor level</i>	Regular ED nurse
	Peer education	<i>I think peer education with young parents would be good because the thing is... they're only actually learning when they actually come into you</i>	GP surgery nurse
	School, nursery, social workers	<i>Certainly social workers might be a valuable way of actually getting information like this into these families... and teachers</i>	Regular ED doctor
	Books	<i>it's easy to flick through a book when your breastfeeding or bottle feeding or whatever</i>	white British mother
		<i>I didn't read the books, it was too much information. You don't want to be bombarded really I don't think</i>	white British mother
	Posters	<i>they used to have a big resuscitation poster that they advised you to put in your children's bedroom... You could have your symptom checker thing on there because you're more likely to read it at the time you don't need it, than the time you do need it</i>	Regular ED nurse
	Information pack for new parents	<i>Because you read everything in that [information] pack because it's your first baby, so every leaflet is important in that [information] pack</i>	Regular ED nurse
	Adverts	<i>Like how many parents come forward and say, "Oh we found out our child had meningitis because we did the glass roll test." I actually think media like that is one of the most powerful way of sort of getting to large groups is to have like it on telly.</i>	white British mother
		<i>A lot of us can't read or write... (parent 1). So I think they do pick up a lot, travellers do rely on the adverts and that a lot more. They take more notice of them kind of things (parent 2).</i>	Travelling community mothers
	Centralised website	<i>if you've got an ill child and you're wanting to find out what it could possibly be, you don't want to spend hours looking for that information, you actually want to be able to go on a site</i>	white British mother

Internet-based resources		<i>If you've got a sick child at home and they're mauning at you, you haven't got the time to go on the internet... you've got a child hanging off your leg going, "Mummy I feel poorly, mummy I want this, mummy I want that," or you know, screaming or, I don't think it's that practical that often you don't have the chance to go on the internet.</i>	white British mother
	Mobile-phone accessible website	<i>yes the phone it's easily accessible and especially when you've got a baby. Rather than putting on the computer....I think the phone is a very good source because you keep it all the time with you. That's a very good thing, yeah.</i>	white British mother
Audiovisual material	Pictures	<i>A picture says a thousand words but it helps. Pictures definitely help.</i>	Regular ED doctor
	Videos	<i>mixed in with some kind of videos of things that you kind of click on to see what it, or pictures to see what it looks like. Because they're saying your breathing faster, but as I said, that's one thing for one person and you know, it might mean something else to somebody else... And give patients and parents that autonomy to say actually no, I've looked at this, this is what it looks like and therefore my child is breathing fast</i>	Paediatric ED doctor

It is important to note that in addition to discussing information resources, parents and clinicians alike highlighted that for worried parents, nothing will replace face-to-face reassurance from a healthcare professional: *"only physical contact with somebody who you trust and feel can answer your question will ever give you the reassurance with regards to a child that you're looking for... ultimately you really just want to speak to someone and show them your child, you want to speak to someone who you feel is experienced and knowledgeable about what you are talking about and can help you with your child"* (white British mother); *"verbal advice can reassure you, I don't think any website or any information can reassure you"* (Regular ED doctor). This message came across particularly strongly from the Asian British community.

DISCUSSION

Principle findings and implications

Co-production

Parents and clinicians described a diverse range of desirable attributes for safety netting advice, as well as techniques for its delivery. This highlights the need for true co-production of safety netting resources by both parents and clinicians, throughout every stage of design and development of resources, to ensure that they meet the range of criteria identified as important by both groups. This mirrors the key principle of the Children and Young People's Health Outcome's Forum regarding family involvement in the development of services (2). Safety netting is a perfect example of where

true co-production by clinicians and parents could result in development of effective resources which will be utilized and valued by both groups.

There were some important differences between groups, for example whilst clinicians in all settings, and many parents, favoured the idea of internet- and phone-based resources, the travelling community highlighted that this would not be appropriate for the current generation of parents; and the Asian British and travelling communities highlighted that some families would not be able to read written English, thus particularly preferring audiovisual materials. However, generally parents and clinicians from different communities/settings suggested a very similar range of content, quality criteria, format and delivery methods for safety netting advice, whilst acknowledging that multiple techniques and resources are needed. (Note, however, that the number of participants from each community/setting was small which limited our ability to draw comparisons.) Previous research in the UK has also found commonality of parental information needs across different socio-economic groups regarding childhood illness (20). The good degree of agreement between the subthemes emerging from the two groups highlights the potential for the development of safety netting techniques which are indeed endorsed by both parents and clinicians. Figure 1 shows desirable safety netting attributes that were proposed by both parents and clinicians: resources should be developed that meet these criteria.

Multifaceted approach

Participants recognized that one approach will not be appropriate for all parents, and that a variety of techniques and resources is needed. For example, written materials are not suitable for those with low literacy or English language; and websites are not suitable for those who lack confidence in, or access to, the internet and smart phones. There may be a need for a tailored approach to meet individual needs.

An information leaflet for parents on feverish illness has already been developed by NICE (21); yet it is not multifaceted or tailored for different groups, which is perhaps the reason why none of the clinicians reported using the leaflet for safety netting. Our study highlights the need for multifaceted, tailored approaches co-produced with parents. The information leaflet meets some of the key criteria presented in Figure 1 (including signs and symptoms to look for, information on illness management, professional endorsement), but it could perhaps be improved by including other key criteria including simple symbols, pictures, videos.

Delivery

Participants were imaginative in their consideration of how safety netting advice could be delivered; ideas included DVDs, television programmes, rolling displays in waiting rooms, posters, booklets, leaflets, flashcards and even quizzes. Media campaigns were thought to have been successful at improving knowledge in other areas of health, and could be applied to childhood illness; however, clinicians warned against creating anxiety. Furthermore, it would be difficult to design and deliver a successful media campaign for such a broad topic as acute childhood illness. Clinicians also warned against falsely reassuring parents; for example emphasizing a non-blanching rash in pictures may

399 prevent children with meningococcal disease being presented before the appearance of this
400 symptom. There is a balance to be met between creating false reassurance and over-anxiety (3).

401 Types of information

402 It was commonly suggested by both parents and clinicians that there is a need for different types of
403 information to be delivered at different times:

- 404 1. Specific information: provided when children are sick (usually during a consultation), specific
405 to the particular illness the child is experiencing
- 406 2. Symptom related information: accessible by parents pre-consultation when their children
407 are sick, could also be provided during a consultation
- 408 3. General information: education for parents on childhood illness in general

409 Regarding specific illness- or symptom-related information, a common proposal was for a well-
410 signposted website on childhood illness, with professional endorsement, that is easy for parents to
411 search, and provides the information they need when their child is sick. Previous research has
412 similarly revealed parental need for consistent advice from a trusted source, and a preference for
413 NHS-branded websites compared to other internet resources (20). Our participants also frequently
414 suggested that this should be compatible for use on mobile phones so that parents can access it
415 easily whilst caring for their child. The inclusion of pictures and videos would increase accessibility. A
416 variety of symbols were suggested which could be used in such resources including sad and happy
417 faces, and different coloured symbols.

418 Parental need for high-quality internet-based resources is not surprising given the evidence that
419 parents are increasingly using the internet to access health information. In two independent surveys,
420 52% of parents had sought health information for their children on the internet (22, 23); however
421 the quality and accuracy of internet advice is variable (24).

422 Regarding general information, both groups suggested that education could be delivered by health
423 visitors, or by peers in the community; with the important caveat of ensuring that the information
424 delivered is correct. We have recently completed a systematic review of the effectiveness of
425 interventions providing information on when to seek medical help for parents of acutely sick
426 children (Neill et al., personal communication). Characteristics of interventions likely to be more
427 effective included comprehensive information, information on how to assess the severity of their
428 child's illness as well as home management advice, and reinforcement from healthcare
429 professionals. These match the key criteria summarized in Figure 1. Interventions which were co-
430 designed with parents were also more effective, again reinforcing the importance of this approach.

431 **Strengths and limitations**

432 This study has taken a first step at identifying the optimal content, format and delivery of
433 information resources for parents of acutely sick young children, from the perspectives of parents
434 and clinicians. Including both parents and clinicians strengthened our study because in order to be
435 effective, resources must be endorsed and valued by both groups. Indeed we identified similar
436 needs from both groups, indicating the possibility of developing resources which are co-produced.
437 Furthermore, we included diverse groups of parents with different literacy levels, information needs,

and ability to use information technology, ensuring that the views of different groups with diverse needs are understood. A range of doctors and nurses from different settings were also included, allowing us to include the perspectives of the broad group of clinicians who provide safety netting advice in different settings. However whilst the maximum variation sampling provided us with participants with a diverse range of characteristics, the qualitative approach means that the extent to which the findings are generalizable to others in the same or different groups and geographical locations is not known. Data were collected and analysed by a team of researchers with different backgrounds, so their range of perspectives helped to reduce bias and facilitated a deeper understanding.

Conclusion

A multifaceted and tailored approach to safety netting is needed, in which information is delivered in multiple ways and is accessible to different groups of parents with varying needs, resources and abilities. It is important that resources are co-produced with both parents and clinicians so that they are accessible to and understood by parents, as well as endorsed by clinicians. This study has shown that it is possible to identify common priorities amongst both groups regarding resource development.

Research is needed into the effectiveness of different components of safety netting resources and the impact on parent knowledge, understanding, satisfaction, anxiety and re-consultation rates, amongst other outcomes. There is also a need for the development of safety netting quality standards to ensure that all clinicians provide parents with appropriate advice, and so that all parents receive the correct information in an efficient way. This study is a first step towards developing testable safety netting interventions and developing an evidence base around safety netting on which to base quality standards.

Authors’ contributions

The study was conceptualized and designed by SN, ML, DR and MT. The data were collected by SN and HS, and analyzed by CJ and SN. CJ drafted the paper; all authors read and approved the final version.

Acknowledgments

We thank the participants for taking part, and all those who coordinated recruitment.

Competing interests

ML was clinical director leading development for the NICE feverish illness guidelines, was a NICE fellow from 2010-2013, and is on the NHS evidence advisory board. The other authors have no competing interests to declare.

Funding

This publication presents independent research funded by the National Institute for Health Research (NIHR) under its Programme Grants for Applied Research funding scheme (RP-PG-0407-10347) and arising from a Career Development Fellowship supported by the NIHR (MT). The views expressed in this publication are those of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health.

ABSTRACT

Objective

To explore the views of parents and clinicians regarding the optimal content, format and delivery of safety netting information for acute childhood illness.

Design

Qualitative study including semi-structured focus groups and interviews.

Setting

First contact care settings, and community centres, children’s centres and nurseries, in the East Midlands, UK.

Participants

Twenty-seven parents from a travelling community, Asian British community, and white British community. Sixteen clinicians including ten doctors and six nurses from a general practice surgery, an out of hours service, and two emergency departments (paediatric and combined adult and paediatric).

Results

Participants described a need for safety netting to contain information on signs and symptoms of serious and common illnesses, illness management, and where and when to seek help. Resources should be basic, simple to use and contain simple symbols. A key criterion was professional endorsement of resources. Internet-based information was desired which is reliable, consistent and up-to-date. Participants described a need for different types of information: that which could be delivered during consultations, as well as more general information for parents to access before consulting a healthcare professional. Face-to-face education, written materials and digital media were suggested delivery mechanisms. Audio-visual material was the preferred by option for families with low literacy. Participants commonly suggested internet-based and phone-based resources, but the travelling community were less comfortable with these approaches.

Conclusions

A multifaceted and tailored approach to safety netting is needed so that effective resources are available for parents with varying information needs, literacy levels and ability to use information technology. We have identified key aspects of content, quality criteria, format and delivery mechanisms for safety netting information from the perspectives of both clinicians and parents. Resources should be co-produced with parents and clinicians to ensure they are valued and utilised by both groups.

ARTICLE SUMMARY

Article focus

- Safety netting could reduce misdiagnoses and avoidable mortality in children, and safely reduce re-attendances to healthcare
- Safety netting has been recommended in the management of acutely sick children by NICE, SIGN and other national groups, but there are no set guidelines regarding the optimal content, format or delivery
- We qualitatively explored the views of clinicians and parents regarding the optimal content, format and delivery of safety netting, which is vital for the development of effective resources

Key messages

- A multifaceted approach is needed to safety netting, with information accessible to different groups with varying information needs, literacy levels and competence in using information technology
- This paper highlights key aspects of safety netting resources that were proposed by both parents and clinicians, which should form the basis of development of future resources
- Safety netting resources should be co-produced by parents and clinicians to ensure they meet the needs of both groups and are maximally effective

Strengths and limitations

- Both parents and clinicians participated, and the findings could form the basis of truly co-produced resources
- We included diverse groups of parents with different information needs and abilities, and clinicians from a range of first contact care settings, to ensure the views of different groups were included; however, the extent to which the findings are generalizable to other groups or populations is not known
- Data were collected and analysed by a team of researchers including clinical and non-clinical, some parents and some not, enabling a deeper understanding

INTRODUCTION

Acute childhood illness is a major contributor to children’s presentation to primary care, and to child mortality. Child and young person mortality has fallen in Europe, but child death rates from treatable causes including asthma, pneumonia and meningitis are higher in the UK than elsewhere in Europe, highlighting a need to better manage acutely sick children (1, 2). The vast majority of children have minor, self-limiting illnesses requiring little or no medical intervention, and it is increasingly difficult for clinicians to identify the very few children with serious illnesses, which often have non-specific presentations and clinical features mimicking those of common, non-serious illness (3). Despite the prevalence of life-threatening acute childhood illness being at an all-time low, there has been an increase in children’s emergency hospital admissions, many of which are for minor illnesses which could have been managed in the community (4, 5). Safety netting information given to parents during consultations advises them about when and where to seek further help (6). As well as aiming to prevent misdiagnoses and avoidable child mortality, there is evidence that safety netting can reduce re-attendances in febrile children (7, 8).

Safety netting was first described by Neighbour over 20 years ago, who proposed it to be a core component of general practice (9). More recently, safety netting has been recommended in the management of acutely sick children by the National Institute for Health and Care Excellence (NICE) (10), Scottish Intercollegiate Guidelines Network (SIGN) (11), other national groups (2, 12), general practitioners (6, 13) and researchers (14); and has been introduced as a NICE quality standard (15). Despite these recommendations, there are no set guidelines regarding the optimal content, format and delivery of safety netting.

Anxiety and uncertainty surround parents’ decisions about when to consult (and re-consult) healthcare professionals during acute childhood illness at home (16, 17). Safety netting could potentially help to reduce these, and provide the more explicit and consistent advice that parents seek (7). However, the most effective components and ways of delivering safety netting have yet to be identified (18, 19), and there is evidence that current safety netting advice may be inadequate. For example a study of 220 feverish children making 570 contacts with urgent care services found that 19% of parents did not recall being given any safety netting advice, and documentation of safety netting advice regarding what to look for was absent in nearly half (43%) of patients’ records (8).

As part of the Acutely Sick Kids – Safety Netting Interventions for Families (ASK SNIFF) project, this study aimed to explore the opinions of parents and first contact clinicians regarding the optimal content, quality criteria, format and delivery of safety netting information. This is vital for the development of effective safety netting materials to increase parental confidence, understanding and satisfaction, decrease uncertainty and anxiety, as well as increase timely and appropriate presentation to primary care. Including and combining the opinions of both clinicians and parents mirrors a key principle of the Children and Young People’s Health Outcome’s Forum, that families must have a voice and be engaged in the development of services (2).

METHODS

We used a qualitative, exploratory approach due to the lack of prior knowledge on the topic. Maximum variation sampling was used to recruit parents from a wide range of communities, and both doctors and nurses working in different first contact care settings, in the East Midlands, UK. Any parents with at least one child under the age of five years ~~old~~, and any clinicians treating children under five years of age at first contact, who were able to speak English, were eligible to participate. We conducted focus groups and/or interviews in each parent community and at each first contact care workplace.

Recruitment was coordinated by email or in person using the local Primary Care Research Network, the Comprehensive Local Research Network for clinicians, and community facilitators, health ambassadors and day nursery/children's centres ~~managers~~ for parents. All participants gave written informed consent. The study was approved by the East Midlands – Nottingham 2 NHS Research Ethics Committee (REC reference 12/EM/0076) and the appropriate research and development offices of each local Trust. Two experienced female researchers (SN, a children's nurse lecturer and HS, a social scientist) facilitated focus groups and interviews between May-December 2012, which were semi-structured and lasted around an hour. Participants were asked a number of questions about provision of safety netting information (see Table 1), and the facilitators used prompts to elicit further details. One facilitator took notes and gave a verbal summary at the end, asking participants to correct misinterpretations and give further comments. Focus groups and interviews were audio recorded, transcribed verbatim, and anonymised.

Table 1: Topic guide for focus groups and interviews

<i>Parents</i>
What information do you want/need to find when your child becomes sick?
Where would you like to find/be given this information?
In what ways, if any, would you like to see access to information improved?
In what ways, if any, do you think the information provided needs to be improved?
<i>Clinicians</i>
What safety netting information do you think parents of sick young children should be given?
How do you think they should be given this information?
In what ways, if any, do you feel the safety netting information available needs to be improved?
In what ways, if any, would you like to see access to information improved?

Data were analysed using ~~the~~ grounded theory ~~approach~~ method of constant comparison. Three main themes were pre-determined by the research question and topic guide (content, quality criteria, and format/delivery of safety netting). Codes and subthemes within each of these themes were developed according to the content of focus groups/interviews. Separate coding schemes were devised for parent and clinician data, according to the content of focus groups/interviews with many of the codes occurring in both the parent and clinician coding schemes, and they were edited as Throughout the process of data collection and analysis progressed, codes were edited, combined and new ones added, and codes were grouped together as subthemes were developed within each theme. The coding schemes were developed together by CJ (a non-clinical researcher) and SN (a children's nurse lecturer), who allocated text to codes accordingly. CJ coded the clinician data and SN coded the parent data, and each researcher checked the other's coding. Both researchers were

familiar with the content of all focus groups/interviews, and both coding schemes. Emerging subthemes, and comparisons between parent and clinician data, were discussed and developed amongst the wider research team. The constant comparative method enabled us to identify similarities and differences within the data coded to the same and different subthemes from parents and clinicians.

RESULTS

Participants

Participants included 27 parents and 16 clinicians. Parents were from a travelling community (recruited via a community facilitator), an Asian British community (recruited at a local community centre and a children’s centre), and the white British community (recruited from a children’s centre and a private nursery) (see Table 2). Clinicians were included from a general practice surgery, a District General Hospital (DGH) emergency department (ED) (treating adults and children), a paediatric ED and an out-of-hours service (OOHS) (see Table 3).

Table 2: Characteristics of participating parents

Characteristics of parents		Number of parents
Community	Travelling families	6
	Asian British	11
	White British	10
Gender	Female	24
	Male	3
Age	under 20 years	1
	20-29 years	5
	30-39 years	16
	40-49 years	5
Adults in the household	Single parent household	5
	Two parent household	18
	More than two adult household	4
Number of children*	1 child	6
	2 children	8
	3 children	5
	4 or more children	6

*Data on number of children are missing for two parents

	50+ years	2

Below we present the three main themes – content, quality criteria and format/delivery of safety netting – and the subthemes within them ~~main themes emerging from the data regarding parents' and clinicians' desires for safety netting, under the categories of content, quality criteria and delivery. Tables 4, 5 and 6 display each theme respectively and the subthemes within them, with quotes to illustrate aspects of our interpretation of the data within each of the subthemes.~~

Safety netting content

There was consensus among clinicians working in the different settings that paediatric illness is broad, and safety netting advice should focus on signs and symptoms of the most serious and most common childhood illnesses: *"It's the nasty ones that you want to catch and the very common things that people will have never seen before but are OK"* (DGH ED doctor). Some clinicians thought that in addition to specific advice given during consultations, there is a need for generic advice or education: *"perhaps there could be... more kind of generic advice about unwell children"* (OOHS GP); *"instant access [to information] doesn't really help because you need to build up your knowledge long before the child becomes ill"* (regular ED doctor). This emphasises the potential need for two different resources: a diagnosis or illness-related safety netting resource for use during/post-consultation, and a more general educational resource for use pre-consultation.

Clinicians described the importance of signposting parents to different services according to illness severity, and providing information on illness management. Primary care staff focused on the need to educate parents about when to care for their child at home or visit the pharmacy, whereas ED staff focused more on the need to communicate what signs and symptoms indicate that parents should attend an ED immediately.

Parents' needs for information matched those of clinicians, described a need for similar information, namely when to worry, and what symptoms are associated with the most common and most serious illnesses (particularly meningitis), and when/where to access help. After receiving a diagnosis, information is wanted on illness causation, management and trajectory: *"Where I ask every question under the sun. What is it, why did they get that, how many times will they get it again?"* (travelling community mother). ~~When and where to access help was another key component of content: "Is it phone, such and such, is it take to A&E, you know, is it wait till the morning, see how it is?" (white British mother).~~

<u>Most serious and most common childhood illnesses</u>	<u>I don't think it's going to be possible to inform everybody about every kind of conditions that are out there, but there may be some that we can consider the common ones and more serious ones, you know</u>	<u>Asian British father</u>
<u>Signposting to different services</u>	<u>Is it phone, such and such, is it take to A&E, you know, is it wait till the morning, see how it is?</u>	<u>White British mother</u>

Safety netting quality criteria

Clinicians and parents alike stated that safety netting resources should be basic, simple to use, with simple messages. Simple symbols and colour indicators were suggested for presenting safety netting information visually, which would be particularly useful for people who are unable to easily understand written information. Suggestions included ticks and crosses, sad and happy faces, traffic lights, red and green: “a picture with a green smiley face, a meningococcal septicaemia rash with a big upset blue light on top of it type face or something like that” (DGH ED doctor). Both parents and clinicians felt that information should be provided in simple language, as well as multiple languages; and that it should be symptoms-based because parents would not always know their child’s diagnosis when searching for information.

Importantly, it was commented that written information, including internet-based resources, should be easy and quick to access: “I think it’s just being able to access information very quickly...” (white British mother). However one clinician raised a caveat: “you’ve got to be very careful with the information that you are putting out there, because you don’t want to drive the paranoia more that there is” (paediatric ED doctor).

A key quality criterion identified by both parents and clinicians was professional endorsement: “I think if it was NHS backed you’d kind of have a bit more trust” (white British mother). Publicity was also highlighted: “it needs to be publicised that patients know to access that site, whereas what’s happening now is that they’re accessing Google and getting a whole lot of symptoms which, y’know, lots of them are not necessarily useful and, erm, heightens the anxiety” (GP surgery doctor). These criteria were described particularly in relation to internet-based safety netting resources: currently, searching the internet generates an ‘overload’ of information, some of which is not useful, which creates uncertainty and anxiety amongst parents. Access to reliable, consistent, up-to-date internet-based information was commonly requested: “the problem is I think the information’s there, it’s not all in one place, it’s all over different websites and if the Department of Health was able to somehow streamline the advice nationally and set up a process of okaying national advice for parents... I think that would be the way to do it” (paediatric ED doctor).

It was suggested that parents need resources which are portable, particularly when caring for a distressed child. Different methods were suggested for achieving this, including providing portable hard copy: “You’ve got them clung to you cause they’re unwell, you’re not going to sit at a computer” (GP surgery nurse); “I think they sort of produce sort of credit card sized things they can give out... so perhaps more of those sorts of resources” (OOHS GP). Alternatively, phone-based internet access could provide quick and easy access to information: “I would do it on my phone, oh yeah, yeah, yeah,

very much so. And that I actually find easier than picking up the phone because if you've got a crying child, trying to pick up the phone and talk to somebody is actually a lot more difficult than having a quick look on the internet to see..." (white British mother).

Table 5: Subthemes and illustrative quotes within the Safety Netting Quality Criteria theme

Subtheme	Illustrative quote	
Basic	<i>It needs to be absolute almost so simple basic</i>	GP surgery doctor
Simple symbols, colours	<i>Simple visual things like a tick and a cross. Lots of people know that a cross is not a good thing or it's a danger. Anything in red, anything green is good... or a sad face or a happy face</i>	Asian British mother
Multiple languages	<i>The information that comes out actually needs to be in multiple languages as well</i>	Regular ED doctor
Symptoms-based	<i>of course a lot of the time you don't know the diagnosis so, yeah, so it's important it isn't sort of restricted to a diagnosis really I think.</i>	OOHS GP
Professional endorsement	<i>Obviously it has to be audited and have involvement with the government.</i>	Asian British mother
Publicised	<i>half of it would be the media in letting the parents know that is out there, because half of these things you don't know that they exist and you don't know what to trust.</i>	white British mother
Easy and quick to access	<i>I think it's just being able to access information very quickly</i>	white British mother
Portable	<i>Nothing that adds to your weight of your bag</i>	white British mother
	<i>I always tend to keep a lot of stuff like that in her bag so I always know where it is and if I'm with her, her bag's always around anyway, so I would prefer that.</i>	white British mother

Format and delivery of safety netting

As described above, participants described a need for different types of safety netting resources including those delivered during consultations, and those accessed prior to consultation. They also acknowledged that information should be provided in multiple formats: "It can be on different forms of media, Internet. Obviously, Internet may not be accessible to many people and if it is accessible, they may not be able to go to the right information, right section so having it in different formats will be quite helpful." (Asian British father).

Consultation-based safety netting

Clinicians described how both verbal and written safety netting information could be delivered during consultations, and suggested demonstration of physical signs including tracheal tug, intercostal recession, and slow capillary refill time: "simple things like tracheal recession that are quite easy to demonstrate... just to show them if they come in with that presenting complaint and it's just talking through it isn't it, if you see any of these signs then you need to come straight back then"

~~(DGH ED nurse). Provision of written materials during consultations could be useful for parents:~~
~~"Well half the time when you're taking your child to the doctors they're not very well, are they, so they're clingy, you've had to probably strip them off... so they're crying and they're trying to tell you all this information and getting them back dressed again really quickly... There is pressure to get out quickly, I think, so I think you do forget what the doctor has said."~~ (white British mother).

Another type of safety netting was referring children to other services such as community children's nurses. Some clinicians thought that written safety netting materials should be tailored to the local area accordingly: *"a bit more specific to the area as well, that would be good so it was, you know it takes into account sort of local pathways, what's available locally including things like the community children's nurses"* (OOHS GP). Conversely, one parent ~~also~~ highlighted the need for standardised advice: *"It should be across nationally and so on, so that everyone is getting the same message"* (Asian British mother).

Pre-consultation education

Safety netting resources for use prior to consultation included general preparatory educational ~~al~~ information to be accessed prior to illness occurring; and more specific information for parents to access during acute childhood illness, before they consult a healthcare professional.

Educational methods suggested by clinicians included education by health visitors, and peer education so that parents can learn from the experiences of others – a caveat being that the information is correct: *"actually learning by somebody else's experience what happened and what were you told and it's getting that because peer education, if it's correct, 'cause that's another reason why we get to see people, 'cause another relative has sent them in and said you must be seen, because advice has changed..."* (GP surgery nurse). Other suggestions were delivery by school/nursery teachers and social workers. Parents ~~had similar suggestions to clinicians, namely also suggested~~ education on childhood illnesses by health visitors ~~and~~ schools/nurseries; ~~as well as novel suggestions including, as well as~~ libraries, community centres, and GP surgeries (in waiting rooms as well as during consultations). They also suggested community based delivery systems including community champions, community educational programmes (such as short courses in community centres), and community snowballing (whereby healthcare professionals provide initial educational sessions, then peers provide these sessions afterwards).

Written materials were suggested for educating parents prior to their child becoming ill: ~~:"they used to have a big resuscitation poster that they advised you to put in your child's bedroom... you could have your symptoms checker thing on there because you're more likely to read it at the time you don't need it, than the time you do need it"~~ (DGH ED nurse). Both parents and clinicians mentioned posters, and suggested the information pack for new parents as a way to deliver written information (although parents did comment that they did not use the information provided in this pack beyond the neonatal period). Other parental suggestions for written materials included booklets, leaflets, flash cards, and small quizzes. Both parents and GPs had limited knowledge of the information on childhood illness currently contained in the personal child health record ("red book"), and felt that it was not well-used by parents or GPs; hence building on the information contained there, ~~or introducing new books,~~ may not be an effective mechanism to educate parents about childhood illness: *"I think I possibly looked at it when I was a new mum with you know, so much enthusiasm,*

and then about a week in I was like... I'm far too tired to do this, there's no way I'm reading through that book" (white British mother).

Parents suggested a wide range of digital media which could be used to deliver information, including internet, phone-based media, DVD, television programmes, and rolling displays on waiting room screens. Many parents recalled media campaigns for stroke, and the glass test for non-blanching rash in meningitis. These campaigns appear to have reached all of the social groups in the sample. Parents felt that media campaigns could be successful for acute childhood illness. The GP surgery focus group acknowledged the success of media campaigns and suggested this could work for educating parents on child illness; although it was acknowledged that media campaigns could create anxiety.

Internet-based resources

Internet-based resources such as a centralised website were commonly mentioned by parents and clinicians alike. One resource parents would like is a well-signposted website with NHS endorsement, which is easy to search and appropriate for mobile phones. Parents were in favour of doctors giving out information about a reliable site at the end of consultations. Clinicians indicated they were happy to do this; but it would need to be simple to use: *"you wouldn't want to, yeah, be getting into huge conversations about how you do it... how you access it, so yeah, it would need to be sufficiently simple and accessible"* (OOHS GP).

Similarly to parents, clinicians in all settings suggested that a phone-based app could be successful in helping parents of sick children assess whether/where to seek help: *"World and times are changing, everything is about internet, everything is about apps and I think if you've got something well written and accessible, on the internet with maybe an iPhone app, an android app, that people can download y'know, some sick kids guide or something like that with a bit of a symptom checker and robust, this is what paediatricians, this is what GP's, this is what emergency physicians would advise you to do, then I think people will take that seriously, and I suspect it would cut down the attendance rate at all different places plus make people a lot more happy"* (DGH ED doctor). However, the travelling community highlighted that the current generation of parents are often unfamiliar with information technology: *"But the new generation when they get a bit older, in a couple of years from now, cause all the children now they're all permanently at school that would help them but not for all us, not for this generation"* (travelling community mother).

Audiovisual material

A benefit of internet-based resources, highlighted by parents and clinicians, is that they could include short video clips showing signs and symptoms, presenting information that is difficult to explain verbally or in diagrams: *~~"some kind of videos of things that you kind of click on to see what it, or pictures to see what it looks like. Because they're saying you're breathing faster, but as I said, that's one thing for one person and you know, it might mean something else to somebody else. And give patients and parents that autonomy to say actually no, I've looked at this, this is what it looks like and therefore my child is breathing fast"~~* (paediatric ED doctor). Parents suggested clips of sounds of specific coughs (croup, whooping cough), respiratory movements (recession) or the appearance of different rashes (chickenpox, meningitis). Conditions that were suggested for video

format by clinicians, some of which matched those suggested by parents, were croup, wheeze, increased work of breathing, recession, bronchiolitis, dehydrated child, floppy child, seizures and fainting, tracheal tug, capillary refill time, and rashes. Parents highlighted that these could be viewed, for example, on a mobile phone whilst holding a baby. Audiovisual material was the preferred option for families with low literacy: the Asian British and travelling communities highlighted that some families would not be able to read written language. Limitations of audiovisual material were however recognised: “[Doctor 1] Photos are very difficult because even if you look at the different atlases we have for dermatology... [Doctor 2] and each book looks slightly different [Doctor 3] And it can be falsely reassuring can’t it. ‘Cause you have meningococcal disease, you can have a blanching rash” (paediatric ED doctors).

Table 6: Subthemes and illustrative quotes within the Format and Delivery of Safety Netting theme

Subtheme		Illustrative quote	
Consultation-based	Signs and symptoms to look for	<i>simple things like tracheal recession that are quite easy to demonstrate... just to show them if they come in with that presenting complaint and it's just talking through it isn't it, if you see any of these signs then you need to come straight back then</i>	DGH ED nurse
	Information sheets	<i>My doctor did give like an information leaflet... and I did read through it, because like on the Internet, you can get into so many areas and then you know you think, you need to feed your son, but when you've got a sheet at least you can find time to do that</i>	Asian British mother
Pre-consultation education	Health visitors	<i>I think the information almost needs to come before your child's ill at health visitor level</i>	Regular ED nurse
	Peer education	<i>I think peer education with young parents would be good because the thing is... they're only actually learning when they actually come into you</i>	GP surgery nurse
	School, nursery, social workers	<i>Certainly social workers might be a valuable way of actually getting information like this into these families... and teachers</i>	Regular ED doctor
	Books	<i>it's easy to flick through a book when your breastfeeding or bottle feeding or whatever</i>	white British mother
		<i>I didn't read the books, it was too much information. You don't want to be bombarded really I don't think</i>	white British mother
	Posters	<i>they used to have a big resuscitation poster that they advised you to put in your children's bedroom... You could have your symptom checker thing on there because you're more likely to read it at the time you don't need it, than the time you do need it</i>	Regular ED nurse
	Information pack for new parents	<i>Because you read everything in that [information] pack because it's your first baby, so every leaflet is important in that [information] pack</i>	Regular ED nurse

It is important to note that in addition to discussing information resources, parents and clinicians alike highlighted that for worried parents, nothing will replace face-to-face reassurance from a healthcare professional: "only physical contact with somebody who you trust and feel can answer your question will ever give you the reassurance with regards to a child that you're looking for... ultimately you really just want to speak to someone and show them your child, you want to speak to someone who you feel is experienced and knowledgeable about what you are talking about and can help you with your child" (white British mother); "verbal advice can reassure you, I don't think any website or any information can reassure you" (Regular ED doctor). This message came across particularly strongly from the Asian British community.

DISCUSSION

Principle findings and implications

Co-production

Parents and clinicians described a diverse range of desirable attributes for safety netting advice, as well as techniques for its delivery. This highlights the need for true co-production of safety netting resources by both parents and clinicians, throughout every stage of design and development of resources, to ensure that they meet the range of criteria identified as important by both groups. This mirrors the key principle of the Children and Young People’s Health Outcome’s Forum regarding family involvement in the development of services (2). Safety netting is a perfect example of where true co-production by clinicians and parents could result in development of effective resources which will be utilized and valued by both groups.

-There were some important differences between groups, for example whilst clinicians in all settings, and many parents, favoured the idea of internet- and phone-based resources, the travelling community highlighted that this would not be appropriate for the current generation of parents; and the Asian British and travelling communities highlighted that some families would not be able to read written English, thus particularly preferring audiovisual materials. However, generally parents and clinicians from different communities/settings suggested a very similar range of content, quality criteria, format and delivery methods for safety netting advice, whilst acknowledging that multiple techniques and resources are needed. (Note, however, that the number of participants from each community/setting was small which limited our ability to draw comparisons.) Previous research in the UK has also found commonality of parental information needs across different socio-economic groups regarding childhood illness (20). There good degree was a great deal of correlation agreement between the subthemes emerging from the two groups, which highlights the potential for the development of safety netting techniques which are indeed endorsed by both parents and clinicians. Figure 1 shows desirable safety netting attributes that were proposed by both parents and clinicians: resources should be developed that meet these criteria.

Multifaceted approach

Participants recognized that one approach will not be appropriate for all parents, and that a variety of techniques and resources is needed. For example, written materials are not suitable for those with low literacy or English language; and websites are not suitable for those who lack confidence in, or access to, the internet and smart phones. There may be a need for a tailored approach to meet individual needs.

An information leaflet for parents on feverish illness has already been developed by NICE (21); yet it is not multifaceted or tailored for different groups, which is perhaps the reason why none of the clinicians reported using the leaflet for safety netting. Our study highlights the need for multifaceted, tailored approaches co-produced with parents. The information leaflet meets some of the key criteria presented in Figure 1 (including signs and symptoms to look for, information on

illness management, professional endorsement), but it could perhaps be improved by including other key criteria including simple symbols, pictures, videos.

Delivery

Participants were imaginative in their consideration of how safety netting advice could be delivered; ideas included DVDs, television programmes, rolling displays in waiting rooms, posters, booklets, leaflets, flashcards and even quizzes. Media campaigns were thought to have been successful at improving knowledge in other areas of health, and could be applied to childhood illness; however, clinicians warned against creating anxiety. Furthermore, it would be difficult to design and deliver a successful media campaign for such a broad topic as acute childhood illness. Clinicians also warned against falsely reassuring parents; for example emphasizing a non-blanching rash in pictures may prevent children with meningococcal disease being presented before the appearance of this symptom. There is a balance to be met between creating false reassurance and over-anxiety (3).

Types of information

It was commonly suggested by both parents and clinicians that there is a need for different types of information to be delivered at different times:

1. Specific information: provided when children are sick (usually during a consultation), specific to the particular illness the child is experiencing
2. Symptom related information: accessible by parents pre-consultation when their children are sick, could also be provided during a consultation
3. General information: education for parents on childhood illness in general

Regarding specific illness- or symptom-related information, a common proposal was for a well-signposted website on childhood illness, with professional endorsement, that is easy for parents to search, and provides the information they need when their child is sick. Previous research has similarly revealed parental need for consistent advice from a trusted source, and a preference for NHS-branded websites compared to other internet resources (20). ~~It was~~ Our participants also frequently suggested that this should be compatible for use on mobile phones so that parents can access it easily whilst caring for their child. The inclusion of pictures and videos would increase accessibility. A variety of symbols were suggested which could be used in such resources including sad and happy faces, and different coloured symbols.

Parental need for high-quality internet-based resources is not surprising given the evidence that parents are increasingly using the internet to access health information. In two independent surveys, 52% of parents had sought health information for their children on the internet (22, 23); however the quality and accuracy of internet advice is variable (24).

-Regarding general information, both groups suggested that education could be delivered by health visitors, or by peers in the community; with the important caveat of ensuring that the information delivered is correct.

We have recently completed a systematic review of the effectiveness of interventions providing information on when to seek medical help for parents of acutely sick children (Neill et al., personal

communication). Characteristics of interventions likely to be more effective included comprehensive information, information on how to assess the severity of their child’s illness as well as home management advice, and reinforcement from healthcare professionals. These match the key criteria summarized in Figure 1. Interventions which were co-designed with parents were also more effective, again reinforcing the importance of this approach.

Strengths and limitations

This study has taken a first step at identifying the optimal content, format and delivery of information resources for parents of acutely sick young children, from the perspectives of parents and clinicians. Including both parents and clinicians strengthened our study because in order to be effective, resources must be endorsed and valued by both groups. Indeed we identified similar needs from both groups, indicating the possibility of developing resources which are co-produced. Furthermore, we included diverse groups of parents with different literacy levels, information needs, and ability to use information technology, ensuring that the views of different groups with diverse needs are understood. A range of doctors and nurses from different settings were also included, allowing us to include the perspectives of the broad group of clinicians who provide safety netting advice in different settings. However whilst the maximum variation sampling provided us with participants with a diverse range of characteristics, the qualitative approach means that the extent to which the findings are generalizable to others in the same or different groups and geographical locations is not known. Data were collected and analysed by a team of researchers with different backgrounds, so their range of perspectives helped to reduce bias and facilitated a deeper understanding.

Conclusion

A multifaceted and tailored approach to safety netting is needed, in which information is delivered in multiple ways and is accessible to different groups of parents with varying needs, resources and abilities. It is important that resources are co-produced with both parents and clinicians so that they are accessible to and understood by parents, as well as endorsed by clinicians. This study has shown that it is possible to identify common priorities amongst both groups regarding resource development.

Research is needed into the effectiveness of different components of safety netting resources and the impact on parent knowledge, understanding, satisfaction, anxiety and re-consultation rates, amongst other outcomes. There is also a need for the development of safety netting quality standards to ensure that all clinicians provide parents with appropriate advice, and so that all parents receive the correct information in an efficient way. This study is a first step towards developing testable safety netting interventions and developing an evidence base around safety netting on which to base quality standards.

475 **Authors' contributions**

476 The study was conceptualized and designed by SN, ML, DR and MT. The data were collected by SN
477 and HS, and analyzed by CJ and SN. CJ drafted the paper; all authors read and approved the final
478 version.

480 **Acknowledgments**

481 We thank the participants for taking part, and all those who coordinated recruitment.

483 **Competing interests**

484 ML was clinical director leading development for the NICE feverish illness guidelines, was a NICE
485 fellow from 2010-2013, and is on the NHS evidence advisory board. The other authors have no
486 competing interests to declare.

488 **Funding**

489 This publication presents independent research funded by the National Institute for Health Research
490 (NIHR) under its Programme Grants for Applied Research funding scheme (RP-PG-0407-10347) and
491 arising from a Career Development Fellowship supported by the NIHR (MT). The views expressed in
492 this publication are those of the author(s) and not necessarily those of the NHS, the NIHR or the
493 Department of Health.
