## 1 Abstract

### 2 Introduction:

3 The impact of work-related musculoskeletal disorders (WRMSDs) is  
4 considerable. The assessment of work tasks with physical exposures is crucial  
5 to estimate the work-related health risks of exposed employees. Three Key  
6 Indicator Methods (KIMs) are available for risk assessment regarding manual  
7 lifting, holding and carrying of loads (LHC), manual pulling and pushing of loads  
8 (PP) and manual handling operations (MHO). Three further KIMs for risk  
9 assessment regarding whole-body forces (BF), awkward body postures (ABP),  
10 and body movement (BM) have been developed de novo. In addition, the  
11 development of a new combined method for mixed exposures (ME) is planned.  
12 All methods will be validated regarding face validity, reliability, convergent  
13 validity, criterion validity and further aspects of utility under practical conditions.

### 14 Methods and analysis:

15 As part of the joint project MEGAPHYS, a mixed methods study is being  
16 designed for the validation of KIMs and conducted in companies of different  
17 sizes and branches in Germany. Workplaces are documented and analysed by  
18 observations, applying KIMs, interviews and assessment of environmental  
19 conditions. Furthermore, a survey among the employees at the respective  
20 workplaces takes place with standardised questionnaires, interviews and  
21 physical examinations with special emphasis on musculoskeletal complaints  
22 and symptoms. It is intended to include 1,200 employees at 120 different  
23 workplaces. For the analysis of the quality criteria, the recommendations of the  
24 COSMIN checklist (COnsensus-based Standards for the selection of health  
25 Measurement INstruments) will be taken into account.

### 26 Ethics and dissemination:

27 The study was planned and conducted in accordance with the German medical  
28 professional code and the Helsinki Declaration as well as the German Federal  
29 Data Protection Act. The design of the study was approved by Ethics  
30 Committees. We intend to publish the validated KIMs in 2018. Results will be

1 published in peer-reviewed journals, presented at international meetings and  
2 disseminated to actual users for practical application.  
3

## 4 **Keywords**

5 Risk assessment, Key Indicator Method, Work-related musculoskeletal  
6 disorders, Reliability, Criterion validity, Convergent validity  
7

## 8 **Strengths and limitations of this study**

- 9 • This research project will provide a scientific substantiation and – if  
10 necessary according to the results of the study – modification of  
11 standardised methods to assess physical exposures at workplaces at a  
12 screening level.
- 13 • With the help of these KIMs, the full range of physical exposures  
14 (excluding exposures due to hand / arm and whole-body vibration) could  
15 be assessed by occupational health and safety stakeholders.
- 16 • Knowledge about the correlation between work-related factors and MSDs  
17 will be advanced.
- 18 • The study is limited by the cross-sectional design, which is not suitable  
19 to assess the causal relationship between variables but only  
20 associations.  
21  
22

# 1 Main text

## 2 INTRODUCTION

### 3 General background

4 Work-related musculoskeletal disorders (WRMSDs) have been recognised for  
5 many decades[1, 2]. Disorders often mentioned in the literature include low  
6 back pain and intervertebral disc diseases[3], epicondylitis[4] and carpal tunnel  
7 syndrome[5]. Hard physical work may also lead to high cardiovascular strain  
8 and may increase the mortality risk of ischaemic heart disease in individuals  
9 with a low or moderate fitness level[6].

10 According to the European Council Directive 89 / 391 / EEC of 12 June 1989 on  
11 the introduction of measures to encourage improvements in the safety and  
12 health of workers at work, the employer must perform an assessment of the  
13 risks to safety and health at work, including those to which specific groups of  
14 workers are exposed[7]. One year later, a further European Council Directive  
15 90 / 269 / EEC “manual handling of loads” of 29 May 1990 was published  
16 addressing the minimum health and safety requirements for the manual  
17 handling of loads where there is a risk particularly of back injury to workers[8].  
18 To assess the risk of WRMSDs, a number of assessment methods have been  
19 developed[9].

### 22 Previous development and validation of the KIMs

23 In Germany, the release of the two European Council Directives triggered the  
24 development of “Key Indicator Methods” (KIMs), see Figure 1. The KIMs were  
25 developed for risk assessment at the screening level in the case of physical  
26 exposures. Potential users include occupational safety and health stakeholders  
27 and industrial engineers in companies, ergonomists, occupational health  
28 physicians, employers and employees associations, and insurance companies  
29 or research facilities. Three different KIM worksheets, one for Lifting, Holding,  
30 Carrying loads (KIM-LHC), one for Pulling and Pushing loads (KIM-PP) and one  
31 for Manual Handling Operations (KIM-MHO), are available so far. These  
32 methods were developed by the Federal Institute for Occupational Safety and

1 Health (BAuA) in close collaboration with practitioners, safety representatives,  
2 occupational health physicians, and the “Länderausschuss für Arbeitsschutz  
3 und Sicherheitstechnik” (Federal Committee of the States for Occupational  
4 Safety and Health)[10, 11, 12]. Briefly, work characteristics such as force,  
5 frequency and duration, and general working conditions are assessed by  
6 means of the KIM, and a score is calculated to summarise the work-associated  
7 risk for adverse health outcomes, e.g. musculoskeletal symptoms. To illustrate  
8 the result, the score is transformed into a traffic light scale indicating a low  
9 exposure situation where physical overload is unlikely to occur (= green),  
10 situations with slightly increased (= greenish yellow) and substantially  
11 increased (= yellow) exposure, up to a high exposure situation where physical  
12 overload is likely to occur and a redesign of the workplace is probably  
13 necessary (= red)[13]. The existing methods can be downloaded from the  
14 homepage of BAuA[14]. The three existing KIMs deal with manual handling of  
15 loads and repetitive manual handling operations. Further aspects of physical  
16 exposures, such as awkward body posture, whole-body forces and body  
17 movement have not or not sufficiently been included in this method inventory  
18 yet. To fill this gap, drafts of three supplemental methods were developed.  
19 Further developments are necessary and a revision of the three existing  
20 methods is required, so that all methods are compatible. In addition, the  
21 development of a method for the assessment of mixed physical exposures is  
22 planned.

23

#### 24 **Preliminary work – development of new KIM drafts**

25 The preliminary work during the last decades mentioned above (see Figure 1),  
26 was complemented by an additional search of peer-reviewed articles and grey  
27 literature predominantly in German and English, and methods for the  
28 assessment of working conditions associated with physical exposures were  
29 analysed systematically. The various methods included on the one hand a large  
30 number of work characteristics considered to be related to health outcomes,  
31 and on the other hand a large number of different body regions, symptoms and  
32 diseases which could be affected by these work characteristics. There is only

1 low evidence of a “cause and effect model” or even a “dose response  
2 relationship” with certainty between most physical exposures and MSDs. In the  
3 published studies or methods, the selection of the observed characteristics  
4 varied significantly. Unfortunately, details about the selection of the parameters  
5 were often not indicated in the publications available and many questions  
6 remain, e.g. questions about the deduction or the combination of the  
7 parameters to be assessed for description of work-related risks. In addition,  
8 only a small number of methods assessing biomechanical exposures in  
9 occupational settings have been tested in a systematic manner for validity,  
10 reliability, or other aspects related to their practical use[9].

11 The development of the new KIMs drafts was based on a comprehensive and  
12 critical literature review of the methods mentioned above. This knowledge was  
13 combined with interviews involving scientists, supervisors of state agencies and  
14 professional associations, occupational physicians, occupational health and  
15 safety officers, and managers from companies in various industries about  
16 typical kinds of exposures and exposure-structures of physical exposures.  
17 Finally, the drafts of three new KIMs (whole body forces, awkward postures,  
18 and body movement) were available for validation within the present study.

## 19 20 **METHODS AND ANALYSIS**

### 21 **Aim, design and setting**

22 In this study protocol, the concept for development and validation of the newly  
23 developed and redesigned KIMs is presented. It is part of a joint project  
24 (MEGAPHYS – Mehrstufige Gefährdungsanalyse physischer Belastungen am  
25 Arbeitsplatz [Multilevel risk assessment of physical exposures at work]). The  
26 distribution of the responsibility for the recruitment and documentation of the  
27 workplaces and the realization of the interviews of further partners in the joint  
28 project are described in the “Funding” and “Acknowledgements” sections.  
29 General aims, definition of the six archetypes of physical workload used and  
30 the background of the joint project MEGAPHYS have been described  
31 previously[15].

1 The aim of the study protocol presented here is to provide the concept of how  
2 to validate the revised versions of the three existing KIMs (KIM LHC, KIM PP,  
3 KIM MHO) and the draft versions of the three new KIMs for whole body forces,  
4 awkward postures, and body movement (KIM ABP, KIM BF, KIM BM) in order  
5 to provide validated risk assessment methods for these six types of physical  
6 exposures. Furthermore, a draft of a KIM for the assessment of mixed physical  
7 exposures, including relevant indicators of the six specific KIMs, is also planned  
8 (see Tables 1 and 2). The main objective to be considered is the association  
9 between physical exposures, as assessed by means of the scores of the KIMs,  
10 and the frequency of musculoskeletal symptoms and other outcomes within the  
11 exposed workers in terms of discriminative capacity of the KIMs or the  
12 combined KIM.

13 The validation of KIM uses a cross-sectional design and a mixed-method  
14 approach. For the determination of criterion validity, a cross-sectional study  
15 among 1,200 employees at approx. 120 different workplaces will be carried out.  
16 Workplace analyses will be done by direct observations and assessments using  
17 the KIMs, interviews of employees and managers, workplace measurements  
18 (e.g. noise, climate) and video recordings. These workplace analyses will also  
19 be used for the determination of face validity, reliability, convergent validity,  
20 criterion validity and further aspects of utility.

21 Setting of the study will be workplaces in voluntarily participating companies of  
22 different sizes and branches in Germany.

23

#### 24 **Characteristics of participants**

25 For the analysis of criterion validity, male and female employees, 19 to 65  
26 years of age, at workplaces with different types and levels of physical  
27 exposures are recruited, who have worked at the workplaces considered for at  
28 least three months and are proficient in the German language. For each type of  
29 physical exposure (total of six types: LHC, PP, MHO, BF, ABP, BM) and for  
30 each of four exposure levels as rated by experts beforehand (low, slightly  
31 increased, substantially increased, and high), approximately 40 to 50  
32 employees will be recruited (assuming predominantly uniform exposures in

1 each group). The aim is to cover all employees of the selected workplaces. If  
2 more than 20 employees are engaged in the same workplace, the participants  
3 will be selected randomly. The study population can be calculated as follows: 6  
4 types of physical exposures x 4 exposure levels x 50 subjects per type of  
5 physical exposure and exposure level = 1,200 subjects. Assuming that at each  
6 workplace an average of 10 employees can be recruited, 120 workplaces need  
7 to be observed and documented. It is intended to analyse about 5 workplaces  
8 per type of physical exposure and exposure level. Approx. 10 employees per  
9 workplace will be interviewed by ergonomists, and interviewed and examined  
10 by physicians.

11 The data gathered during observation and documentation of the 120  
12 workplaces will also be used for the determination of convergent validity,  
13 reliability and further aspects of utility. For the determination of interrater-  
14 reliability, 12 users of the KIMs are needed, to represent future users. Typical  
15 users of these kinds of assessment methods ideally are occupational health  
16 and safety stakeholders or industrial engineers in the companies. From these  
17 12 users, six pairs will be formed (one pair per type of physical exposure), each  
18 observing 20 workplaces. This will result in 120 double ratings.

## 20 **Research goals**

21 The research goals (RG) include the examination of different quality criteria of  
22 the KIMs:

- 23 • RG 1: The KIMs are an adequate reflection of the construct to be  
24 measured (face validity).
- 25 • RG 2: At the completion of the KIMs, no relevant deviations occur  
26 between different users assessing the same workplaces (reliability).
- 27 • RG 3: Assessing workplaces using the KIMs and other screening  
28 methods measuring the same type of physical exposure will result in no  
29 relevant differences (convergent validity).
- 30 • RG 4: It is assumed, that employees at workplaces with high physical  
31 exposure show adverse health-related outcomes (e.g. musculoskeletal  
32 symptoms) more frequently than non-exposed workers. It is assumed,

1  
2  
3 1 that high risk scores derived in the assessment of workplaces with the  
4 2 KIMs are associated with a high prevalence of musculoskeletal  
5 3 symptoms and disorders (criterion validity or content validity regarding  
6 4 hypotheses testing).

7  
8  
9 5 The selection of the quality criteria described in the research goals are derived  
10 6 from a systematic evaluation of observational methods assessing  
11 7 biomechanical exposures at work[9]. For the analysis of the quality criteria, the  
12 8 recommendations of the COSMIN checklist (COnsensus-based Standards for  
13 9 the selection of health Measurement INstruments) will be taken into  
14 10 account[16]. The reporting of the results of this observational study will also  
15 11 consider the recommendations of STROBE (Strengthening The Reporting of  
16 12 OBservational studies in Epidemiology)[17].  
17  
18  
19  
20  
21  
22  
23  
24

#### 25 26 14 **Instruments and Methods**

27 15 The instruments and methods for the assessment of exposures and outcomes  
28 16 (i.e. questionnaire, medical diagnostic tool, assessment of working conditions)  
29 17 used in this survey have been used in a similar form in other studies by several  
30 18 authors. Among them, the authors of the present study used them for the  
31 19 assessment of musculoskeletal symptoms in office workers[18] and in a former  
32 20 validation study of the KIM MHO[19, 20].

#### 33 21 1) Assessment of exposures:

34 22 - Ergonomic work procedure analysis and assessment of technical  
35 23 procedures for the documentation of working conditions.

#### 36 24 2) Application of the KIMs:

37 25 - Application of the six KIMs based on the exposure assessment.

#### 38 26 3) Assessment of health outcomes:

39 27 - Standardised questionnaire for a survey among the employees.  
40 28 - Medical diagnostic tool for the physical examination of the employees.  
41  
42

#### 43 30 *Ergonomic work procedure analysis for the assessment of exposures*

44 31 The basis for the evaluation of the workplaces is an ergonomic work procedure  
45 32 analysis with detailed assessment of exposures during the shift. A workplace  
46  
47  
48  
49  
50  
51

57  
58  
59  
60

1 typically consists of a number of different work tasks. Duration and frequency of  
2 all work tasks are documented in a way that the KIMs, as well as further  
3 screening methods chosen for the testing of convergent validity, can be  
4 completed. The ergonomic work procedure analysis covers in principle all  
5 relevant objective characteristics that result from the type of work and the  
6 working conditions. Individual characteristics during work execution, random  
7 disruption of the workflow or unusual conditions will not be considered.  
8 Principal components of the work procedure analysis are:

- 9 1) Metadata of the workplace, such as: name and type of activity, precise  
10 list of work tasks, professional qualification requirements, position of  
11 employees, complexity of the activity, number of employees at the  
12 workplace, gender and age distribution, shift system, typical working  
13 time, predetermination of the work task;
- 14 2) Number and type of work task and for every work task detailed  
15 information, for example: about temporal distribution of this work task  
16 during the shift, determination of type of work (load handling, applying  
17 force, body posture, joint positions); and
- 18 3) Basic description of other relevant exposures, such as: noise level,  
19 lighting, vibration, hazardous materials.

### 21 *Application of the Key Indicator Methods (KIMs)*

22 The application and validation of the KIMs are the central goals of this research  
23 project and will be completed based on the ergonomic work procedure analysis.  
24 The KIMs contain an objective requirement and description of exposures and  
25 identify potential threats to physical overload. The KIMs include job  
26 characteristics and their interaction. The key indicators are classified in different  
27 scales. The scales correspond to conditions in practice and range from a  
28 minimum to maximum, or optimum to poor. The classification of these scales  
29 indicates bottlenecks for each category / indicator. By multiplying the scale  
30 value of the daily duration / frequency of activity with the sum of the other scale  
31 scores, a total value can be calculated. This calculated sum score can be  
32 allocated to an exposure level and one of four risk categories, an approach

1  
2  
3 1 already used in existing KIMs[13]. The four risk categories reflect the increase  
4 2 of the probability of physical overload and correspondingly the increase in  
5 3 frequency of adverse health effect related to the given physical exposure from  
6 4 low (reference group) to high load situations (see above, section “Previous  
7 5 development and validation of the KIMs”).

8 6 An overview of the KIMs, including a brief description of the type of exposure,  
9 7 the key indicators considered and some examples of typical work tasks is  
10 8 provided for the already existing KIMs in Table 1 and for the KIMs under  
11 9 development in Table 2.

For peer review only

1 Table 1: Existing KIMs (to be revised)

Acronym	Focus of this Key Indicator Method (KIM)	Key Indicators to be considered in this KIM	Examples
KIM LHC	Manual Lifting, Holding and Carrying loads $\geq 3$ kg	<ul style="list-style-type: none"> <li>• Daily frequency</li> <li>• Effective load weight</li> <li>• Load handling conditions / location of the load</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this exposure during the shift</li> </ul>	Loading / unloading of bags, sorting packages, loading of equipment without lifting aids, picking
KIM PP	Manual Pushing and Pulling of loads with trucks and monorails	<ul style="list-style-type: none"> <li>• Daily duration and distance</li> <li>• Load weight / transport device</li> <li>• Driveway conditions</li> <li>• Properties of transport device</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this exposure during the shift</li> </ul>	Postal service with cart, picking with containers, waste disposal
KIM MHO	Manual Handling Operations: Work tasks with uniform, repetitive motion and predominantly lower force expenses of the upper extremities during MHO	<ul style="list-style-type: none"> <li>• Daily duration</li> <li>• Type, duration, and frequency of the executing force</li> <li>• Force transfer and gripping conditions</li> <li>• Hand-arm posture during manual work processes</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this exposure during the shift</li> </ul>	Assembly activities (e.g. installation of electrical appliances), sorting, cutting, cashiering, manually controlling, pipetting, microscopy, joining, turning, cutting, moving, wrapping

1 Table 2: New KIMs (to be developed)

Acronym	Focus of this Key Indicator Method (KIM)	Key Indicators to be considered in this KIM	Examples
KIM BF	Whole Body Forces with mostly stationary force application.	<ul style="list-style-type: none"> <li>• Daily duration</li> <li>• Type, duration, and frequency of the executing force</li> <li>• Symmetry of the application of force</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this exposure during the shift</li> </ul>	Working with winches, work with levers, working with pneumatic hammers, working with chainsaws
KIM ABP	Awkward Body Postures including any strenuous postures, which are predestinated by the work process and are long lasting	<ul style="list-style-type: none"> <li>• Duration and temporal distribution of different trunk postures</li> <li>• Duration and temporal distribution of sitting / walking / standing during the day</li> <li>• Duration and temporal distribution of hands above shoulder and far from body</li> <li>• Duration and temporal distribution of kneeling, squatting</li> <li>• Unfavourable working conditions</li> </ul>	Steel fixing (concrete), manual welding, ceiling mounting, work at the microscope, working inside of tanks, microsurgery
KIM BM	Body Movements to a place of work or in a work area, which will be assessed independently of applying force	<ul style="list-style-type: none"> <li>• Body movement and eventually carried load</li> <li>• Location of the load centre</li> <li>• Body movement when driving with transport device</li> <li>• Driveway conditions (if work task includes driving)</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this exposure during the shift</li> </ul>	Climbing tower cranes, control inspections in channels, maintenance on furnaces
KIM ME	Mixed Exposures: combination of the exposures of a shift	<ul style="list-style-type: none"> <li>• Covers the key indicators of the 6 KIMs mentioned above</li> </ul>	Work places with different exposures during the shift

2

### 1 *Standardised questionnaire for the assessment of health outcomes*

2 The employees' questionnaire (conducted in interview) is divided into 4 parts:

- 3 1. Personal details including sociodemographic data (e.g. age, gender,  
4 years on the job, leisure time activities), general information about  
5 current and former occupational activities (e.g. type and amount of  
6 physical exposures, time pressure, shift work, working posture);
- 7 2. Subjective assessments of the exposure in the workplace (questionnaire  
8 of the subjective estimation of exposures – FEBA[21]);
- 9 3. Other psychosocial aspects (e.g. job satisfaction, social support,  
10 commitment; extract from the COpenhagen PSYchOSocial Questionnaire  
11 - COPSOQ[22, 23]); and
- 12 4. Subjective perceived exertion of physical exposures (Borg RPE  
13 scale[24]).

### 14 *Medical diagnostic tool for the assessment of health outcomes*

15 The documentation of the medical interviews is based on the Standardised  
16 Nordic questionnaires for the analysis of musculoskeletal symptoms[25, 26]. To  
17 substantiate the statements of the employees about the musculoskeletal  
18 symptoms in the interviews, a physical examination is performed after the  
19 interview. To derive specific tentative medical diagnoses, a list of standard  
20 diagnoses of musculoskeletal disorders was considered. The medical  
21 diagnostic tool used in the present study was derived from a SALTSA study[27]  
22 and supplemented by a multi-stage diagnosis[28] and further examination  
23 techniques[29]. The diagnostic tool consists of a documentation sheet and a  
24 reference sheet. The documentation sheet is divided into three parts. Part A is  
25 a general survey to document painful or symptomatic body regions. Part B  
26 deals with specific examination techniques to be carried out if pain or  
27 symptoms in specific regions were documented in part A. According to these  
28 results and with assistance of a reference sheet, tentative diagnoses can be  
29 assigned using a list of diagnoses in part C.

- 1  
2  
3 1  
4 2 These are:  
5  
6 3 Diseases of the upper extremities  
7  
8 4 • Cervical / cervicocephal syndrome  
9  
10 5 • Cervicobrachial syndrome  
11  
12 6 • Rotator cuff syndrome, adhesive capsulitis of shoulder  
13  
14 7 • Medial and lateral epicondylitis  
15  
16 8 • Flexor / extensor peritendinitis / tendosynovitis of forearm/wrist region  
17  
18 9 • Carpal tunnel syndrome  
19  
20 10 • Osteoarthritis of the joints of the distal upper extremities

21 Disorders of the lower back

- 22 • Low back pain / lumbago  
23  
24 • Lumbar facet syndrome – pseudo-radicular syndrome  
25  
26 • Lumbar radicular syndrome  
27

28 Disease of the lower extremities

- 29  
30 • Hip osteoarthritis  
31  
32 • Knee osteoarthritis (including chondromalacia patellae)  
33  
34 • Meniscus lesion  
35  
36 • Static insufficiency of foot  
37  
38 • Varicosis of the leg veins  
39

40 Further relevant conditions not included in this list are also recorded.  
41  
42

43 **Data Analysis Plan**

44 *Analysis of RG 1 (face validity)*

45 For the determination of face validity, no statistic procedures are used. Face  
46 validity was derived from preliminary work and a feasibility study, which was  
47 done in preparation prior to the main study[30]. As mentioned above, the six  
48 KIMS were developed based on our own activities during the last decades  
49 including an extensive search of peer-reviewed scientific articles and other grey  
50 literature concerned with methods for the assessment of working conditions  
51 associated with physical exposures. In 2015, the feasibility of the six KIMs were  
52  
53  
54  
55  
56  
57  
58  
59  
60

1 field-tested among 114 workplaces in 40 different companies. At every  
2 workplace, the KIMs were completed and discussed with the respective  
3 occupational health and safety stakeholders in the companies, and developed  
4 further iteratively. Over-all, the KIM forms were completed 615 times during this  
5 process. According to these field-tests, the results seemed to be plausible to  
6 the stakeholders involved and all relevant aspects seemed to be  
7 implemented[28]. The results of this feasibility study were integrated in modified  
8 drafts of the KIMs which are basis for the scientific validation described in the  
9 following research goals and chapters.

#### 10 11 *Analysis of RG 2 (reliability)*

12 It will be analysed, whether relevant deviations between different users  
13 assessing the same workplaces occur. The reliability will be determined by  
14 examining the independence of results assessed by different individuals  
15 (occupational health and safety stakeholders). Descriptive statistics (mean,  
16 median, variance, range) will be used to illustrate the distribution of different  
17 workplace assessments of the involved experts. Interrater-reliability for multiple  
18 raters will be analysed using standard video sequences of typical workplaces  
19 for risk assessment, and rating these videos by a group of selected experts  
20 under standardised conditions[31].

#### 21 22 *Analysis of RG 3 (convergent validity)*

23 It will be analysed, whether relevant differences occur during assessment of  
24 workplaces with the KIMs and with other screening methods measuring the  
25 same type of physical exposure. Data basis for the determination of the  
26 convergent validity are descriptions of the 120 workplaces gathered in the  
27 cross-sectional study. During the selection of the workplaces to be included in  
28 the study, an equal distribution of the six types of physical exposures and the  
29 four exposure levels will be taken into account. It is assumed that an average of  
30 five work tasks can be analysed at any workplace. Thus, around 600 work task  
31 descriptions will be available, 100 descriptions per type of physical exposure.  
32 The KIM provides a score of 1 point to about 200 points (theoretically, point  
33 values > 1,000 are possible, however, these values are unlikely to appear

1 under real conditions). If the respective comparison method also produces a  
2 score, correlation analyses will be performed[32]. The correlation coefficient  
3 and the mean value will be taken into account. If the comparison method does  
4 not produce a score (for example, differs only dichotomously between "green"  
5 and "red"), Cohen's kappa[33] is calculated using the exposure levels of the  
6 KIMs. For the six types of physical exposures for the six KIMs, existing  
7 methods were selected for comparison which meet as many of the criteria as  
8 possible below:

- 9 • Description of quality criteria,
- 10 • Large degree of dissemination,
- 11 • Plausible and comprehensible model, and
- 12 • Pass ability with the concept presented here.

13  
14 *Analysis of RG 4 (criterion validity or content validity regarding hypotheses*  
15 *testing)*

16 It will be analysed, whether employees at workplaces with high physical  
17 exposures show adverse health related outcomes (e.g. musculoskeletal  
18 symptoms) more frequently than non-exposed workers considering relevant  
19 confounders such as age, gender, constitution or disposition. It is assumed,  
20 that high scores derived in the assessment of workplaces with the KIMs are  
21 associated with a high frequency of musculoskeletal symptoms in exposed  
22 workers. Accordingly, low scores in the KIMs resulting at workplaces with low  
23 physical exposures are associated with a low frequency of musculoskeletal  
24 symptoms in workers. The considered (main) outcome region(s) for each type  
25 of physical exposure and each KIM vary. The approximate impact of physical  
26 exposures and outcomes is described schematically in Figure 2.

27 Effect estimates for dichotomous outcomes (prevalence of symptoms) are  
28 prevalence ratios with 95 % confidence intervals per type of physical exposure  
29 and exposure level, as determined by the KIMs. Effect estimates for continuous  
30 outcomes (perceived exertion, WAI) are beta-estimators (increment) with 95 %  
31 confidence intervals per type of physical exposure and exposure level, as

1 determined by the KIMs. The lowest exposure level is regarded as the  
2 reference category (internal control group). The increments are estimated using  
3 linear regression models (IBM-SPSS-Statistics procedure Genlin) under  
4 consideration of confounders (at least: age, sex, BMI, and body height).

5 For each type of physical exposure (each KIM), the following models are  
6 calculated:

- 7 • Minimally adjusted models (age, gender),
- 8 • Moderately adjusted models (age, sex, BMI, body height and other  
9 types of physical exposures), and
- 10 • Maximally adjusted models (age, sex, BMI, body height, other types of  
11 physical exposures, other occupational exposures and other  
12 confounders).

13 Primarily, the moderately adjusted models will be interpreted. As far as possible,  
14 based on the regression models, post hoc assessments of prevalences of the  
15 outcomes for each type of physical exposures will be conducted. Subjects are  
16 excluded from the analyses, if missing data in the different body region occur.  
17 Sensitivity analysis are intended regarding e.g. regional distribution of the  
18 workplaces, company characteristics (size, branche etc.) and gender.

### 20 **Sample Size calculation**

21 For power or sample size calculation the EpiManager-Software[34] and  
22 G\*Power[35] were used.

#### 24 *Power for determination of reliability*

25 For the determination of reliability (RG 2), 12 users of the KIMs are needed, to  
26 represent future potential users. From these 12 users six pairs will be formed,  
27 each observing 20 workplaces. This will result in 120 double ratings. As  
28 statistical measures, correlation coefficients are calculated and comparisons of  
29 mean values are carried out. The assessment of conformity is based on the  
30 following categories: values  $\leq 0.3$  = small;  $> 0.3$  to  $< 0.5$  = low;  $0.5$  to  $< 0.7$  =  
31 good,  $\geq 0.7$  = high correlation.

1  
2  
3 1 In order to demonstrate a correlation (correlation coefficient,  $r$ ) of 0.7 (alpha  
4 0.05 and beta 0.8), about 15 double observations would be necessary. For a  
5 2  
6 3 correlation of 0.8, 10 double observations would be necessary. The target of 20  
7 4  
8 4 double observations per type of physical exposure should ensure an adequate  
9 5  
10 5 study power.

11 6 *Power for determination of convergent validity*

12 7 For the determination of convergent validity (RG 3) workplaces will be assessed  
13 8  
14 8 by scientists experienced in ergonomics using the KIMs and further screening  
15 9  
16 9 methods assessing the same type of physical exposures. A correlation  
17 10  
18 10 coefficient between the KIM and an alternative screening method of  $r = 0.5$  or  
19 11  
20 11 higher is considered to be an adequate correlation[32]. To show that two  
21 12  
22 12 methods correlate at least with an  $r$  of 0.5 or higher ( $H_1: r > 0.5$  vs.  $H_0: r = 0$ ),  
23 13  
24 13 56 records are required for each of the 6 KIMs. If only 30 records per process  
25 14  
26 14 could be evaluated, it can be shown that the two methods correlate with an  $r$  of  
27 15  
28 15 about 0.8 or higher ( $H_1: r > 0.8$  vs.  $H_0: r = 0$ ,  $\alpha < 0.05$ ,  $\beta = 0.8$ ). If the  
29 16  
30 16 comparison method does not produce a score but only categories, Cohen's  
31 17  
32 17 kappa[33] is calculated. In this case, 100 data sets are needed to show  
33 18  
34 18 statistically relevant correlations.

35 19

36 20 *Power for determination of criterion validity*

37 21 As described in RG 4, it is assumed, that employees at workplaces with high  
38 22  
39 22 physical exposures show adverse health-related outcomes more frequently  
40 23  
41 23 than non-exposed workers. The outcomes which will be considered in this study  
42 24  
43 24 are (Table 3):

- 44 25 1) Prevalence of musculoskeletal symptoms (7-day and 12-month) in nine  
45 26  
46 26 body regions (Figure 2),  
47 27  
48 27 2) Prevalence of tentative diagnoses, and  
49 28  
50 28 3) Perceived exertion (Borg RPE scale[24]).

51 29

52 30

53 31

54 32

1

2 *Table 3: Expected outcomes according to exposure levels of the KIMs*

Exposure levels of the KIMs	1) Prevalence of musculoskeletal symptoms	2) Prevalence of tentative diagnoses	3) Perceived exertion (Borg RPE scale)
Low	Reference group	Reference group	Very light
Slightly increased	7-day prevalence increased	12-month prevalence hardly increased	Light
<b>Acceptance level</b>			
Substantially increased	7-day prevalence significantly increased (at least double)	12-month prevalence slightly increased	Somewhat hard
<b>Tolerance level</b>			
High	7-day prevalence significantly increased (at least triple)	12-month prevalence substantially increased	Very hard

3

4 *1) Power for the outcome "prevalence of musculoskeletal symptoms"*

5 The minimum size of study population (at least 40 to 50 subjects per exposure  
6 level, targeted in "characteristics of the participants in the study") is based on  
7 the power calculation. The 7-day prevalence of MSDs among males and  
8 females without physical exposures (office workers) was assessed in  
9 preliminary studies[18]. The 7-day prevalence of MSDs for women was  
10 between 30 % (cervical spine) and 5 % (hip, ankles) and for men between 20 %  
11 (cervical spine) and 5 % (ankles) or 2 % (hip). The 12-month prevalence of  
12 MSDs in men and women without physical exposures was significantly higher,  
13 from 50 % to 65 % (cervical spine) to 10 % (hip, ankle). Assuming an alpha  
14 error of 5 % and a beta error of 80 %, in a group size of 40 persons exposed  
15 and 40 persons not exposed, and assuming a prevalence of 5 % in the  
16 reference group, a prevalence ratio of 6.5 is significantly increased. If the  
17 prevalence of MSDs in the reference group is 20 %, prevalence differences are  
18 detectable by a factor of 2.5. Prevalence differences of this amount between  
19 non-exposed (exposure level: low) and highly exposed employees (exposure  
20 level: high) were observed in the preliminary study mentioned above. It is  
21 therefore expected that variations in prevalence of factors of at least 2 to 6 will  
22 be detectable, when comparing the two highest exposure categories by KIM  
23 with the lowest exposure level (reference group).

### 2) *Power for the outcome “prevalence of tentative diagnoses”*

Due to the expected relatively low incidence of diagnoses in the working population, no statistically significant increase in the prevalence of tentative diagnoses is expected. However, an increasing trend with increasing physical exposure from exposure level “low” to exposure level “high” is expected.

### 3) *Power for the outcome “perceived exertion (Borg RPE scale)”*

The highest limitations in power calculation according to criterion variability result from dichotomous variables as described in the section above (power for the outcome “prevalence of musculoskeletal symptoms”). Therefore, the power of the study according to continuous variables (such as perceived exertion) is high due to the fact that 1,200 subjects will be included in this study. Considering the large number of subjects, small differences of continuous variables between risk category groups are detectable.

### **Quality control and assurance**

The use of standardised and – if available and appropriate – already validated and/or evaluated screening methods as comparison or reference methods ensures high quality of work. All questionnaires will be completed during a face-to-face interview. The work-related physical examination will be performed by trained external physicians. A standardised procedure for physical examination is guaranteed by the specific standardised training of the physicians. Remembering earlier symptoms in a retrospective period could involve a recall bias. In order to minimize the bias and to get a more detailed overview, we ask for the past 7-days prevalence and the 12-month prevalence of symptoms. In addition, a physical examination is carried out. The observation of these three outcomes together might reduce the recall bias.

## 1 **What this study adds**

2 In this study, new KIMs for practical risk assessment of physical exposures are  
3 developed and these new KIMs, as well as the already existing KIMs, will be  
4 validated. The KIMs are a modular tool kit of practical screening methods for  
5 assessing the risk factors associated with work-related musculoskeletal  
6 disorders. In addition, the study will increase the knowledge concerning the  
7 correlation between specific MSDs and characteristics of physical exposures.  
8 With this knowledge, a better classification of occupational hazards with regard  
9 to MSDs will be available in future. This may lead to more specific prevention  
10 strategies.

## 11 **ETHICS AND DISSEMINATION**

### 12 **Ethics approval and consent to participate**

13 The study was planned and conducted in accordance with the German medical  
14 professional code and the Helsinki Declaration of 2013[36] as well as the  
15 German Federal Data Protection Act[37].

16 The design of the study was examined by the Ethics Committee of the  
17 Technical University Darmstadt. The protocol achieved a positive vote  
18 (approval no. EK15/2015 2015-09-22 as supplement to EK2/2013 2013-07-04)  
19 and the Ethics Committee of the Medical Faculty of the University of Tübingen  
20 (004/2016BO2). The study was started after the Ethics Committees gave their  
21 written and unrestricted approval.

22 Employees participate in the study voluntarily. They can end their participation  
23 at any time without reason and without negative consequences, e.g. for their  
24 job. Written informed consent for participation is obtained before the survey.  
25 Employees receive written and verbal information about the main features of  
26 the study as well as about potential benefits for their health and their  
27 contribution to the common public welfare. If they accept the conditions of the  
28 study and their participation, they document their consent with their signature. A  
29 copy of this statement is intended to be kept by the employee for later  
30 reference or cancellation of participation. All original documents are treated  
31

1 according to German Federal Data Protection Act. A comprehensive data  
2 protection concept was approved by the Data Protection Officer of the BAuA.  
3

#### 4 **Timeframe of the study and dissemination of results**

5 The study team started the planning of this project in 2012. The data collection  
6 for the cross-sectional study then started in spring of 2016 and will end in  
7 summer 2017. Description and analysis of the data will be done in 2017. It is  
8 intended to present the approved or revised KIMs to the public in 2018. Results  
9 will be published in peer-reviewed journals, presented at international meetings  
10 and disseminated to actual users for practical application. Potential users  
11 include occupational safety and health stakeholders and industrial engineers in  
12 companies, ergonomists, occupational health physicians, employers and  
13 employees associations, and insurance companies or research facilities.  
14

#### 15 **Acknowledgements**

16 The definitions of six archetypes of physical exposures as well as the  
17 underlying theoretical concept of risk assessment were developed within a  
18 consensual process involving all MEGAPHYS partners. All authors of this  
19 manuscript are MEGAPHYS partners of BAuA. Further MEGAPHYS partners  
20 are the Institute for Occupational Safety and Health of the German Social  
21 Accident Insurance (IFA), the Institute of Ergonomics at the Darmstadt  
22 University of Technology (IAD) and the Leibniz Research Centre for Working  
23 Environment and Human Factors (IfADo). IFA is responsible for the recruitment  
24 of 50 % of the workplaces and contributes to the documentation of all 120  
25 workplaces. IAD is responsible for the documentation of 50 % of the workplaces  
26 and the execution of 50 % of the described interviews. The physical  
27 examinations of the employees are performed by trained physicians of the Kern  
28 Medical Engineering GmbH (KME), Frankfurt, in cooperation with Prof. Rieger,  
29 head of the Institute of Occupational and Social Medicine and Health Services  
30 Research, University Hospital of Tuebingen. The authors thank Paul Kahle for  
31 the English language check.  
32

## 1 **Competing interests**

2 The authors declare that they have no competing interests.

3

## 4 **Funding**

5 The (further) development and validation of the KIMs is part of a joint project  
6 (MEGAPHYS – Mehrstufige Gefährdungsanalyse physischer Belastungen am  
7 Arbeitsplatz [Multilevel risk assessment of physical exposures at work]) funded  
8 by the Federal Institute for Occupational Safety and Health (BAuA) and the  
9 German Social Accident Insurance (DGUV). Project reference numbers are  
10 F2333 (BAuA) and FF-FP0358 (DGUV).

11

## 12 **Authors' contributions**

13 All authors were involved in the conception and design of the study, and the  
14 preparation of this manuscript. US developed the first drafts of the KIMs and  
15 initiated this study. AK and FL concretised the salient content points of this  
16 protocol, such as selection of validation criteria and power calculation. AK had  
17 the lead management in preparation of the study protocol. US, AK, PS, HG, AS,  
18 BH, MS and FB form the development team of the new KIMs. All Authors were  
19 closely involved in the planning and development of the study design and  
20 preparing the study protocol. All authors read and approved the final  
21 manuscript.

**STROBE 2007 (v4) checklist of items to be included in reports of observational studies in epidemiology\***  
**Checklist for cohort, case-control, and cross-sectional studies (combined)**

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2-3
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-6
Objectives	3	State specific objectives, including any pre-specified hypotheses	8
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	6-7
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6-8, 22-23
Participants	6	<del>(a) Cohort study—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow up</del> <del>Case-control study—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls</del> <del>Cross-sectional study—Give the eligibility criteria, and the sources and methods of selection of participants</del>	7
		(b) Cohort study—For matched studies, give matching criteria and number of exposed and unexposed Case-control study—For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	9-15
Bias	9	Describe any efforts to address potential sources of bias	21
Study size	10	Explain how the study size was arrived at	not applicable yet
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	15-21
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	15-21
		(b) Describe any methods used to examine subgroups and interactions	15-21
		(c) Explain how missing data were addressed	18
		(d) Cohort study—If applicable, explain how loss to follow up was addressed Case-control study—If applicable, explain how matching of cases and controls was addressed	not applicable

For peer review only - <http://bmjopen.bmj.com/site/about/guidelines.xhtml>

		<i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	
		(e) Describe any sensitivity analyses	not applicable yet
<b>Results</b>			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	not applicable yet
		(b) Give reasons for non-participation at each stage	not applicable yet
		(c) Consider use of a flow diagram	not applicable yet
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	not applicable yet
		<del>(c) Cohort study—Summarise follow up time (eg, average and total amount)</del>	
Outcome data	15*	<del>Cohort study—Report numbers of outcome events or summary measures over time</del>	
		<del>Case control study—Report numbers in each exposure category, or summary measures of exposure</del>	
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	15-21
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	not applicable yet
		(b) Report category boundaries when continuous variables were categorized	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	
<b>Discussion</b>			not applicable yet
Key results	18	Summarise key results with reference to study objectives	
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	
<b>Other information</b>			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	24

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at [www.strobe-statement.org](http://www.strobe-statement.org).

## 1 Abstract

### 2 Introduction:

3 The impact of work-related musculoskeletal disorders (WRMSDs) is  
4 considerable. The assessment of work tasks with physical workloads is crucial  
5 to estimate the work-related health risks of exposed employees. Three Key  
6 Indicator Methods (KIMs) are available for risk assessment regarding manual  
7 lifting, holding and carrying of loads (LHC), manual pulling and pushing of loads  
8 (PP) and manual handling operations (MHO). Three further KIMs for risk  
9 assessment regarding whole-body forces (BF), awkward body postures (ABP),  
10 and body movement (BM) have been developed de novo. In addition, the  
11 development of a newly drafted combined method for mixed exposures (ME) is  
12 planned. All methods will be validated regarding face validity, reliability,  
13 convergent validity, criterion validity and further aspects of utility under practical  
14 conditions.

### 15 Methods and analysis:

16 As part of the joint project MEGAPHYS (Multilevel risk assessment of physical  
17 workloads), a mixed-methods study is being designed for the validation of KIMs  
18 and conducted in companies of different sizes and branches in Germany.  
19 Workplaces are documented and analysed by observations, applying KIMs,  
20 interviews and assessment of environmental conditions. Furthermore, a survey  
21 among the employees at the respective workplaces takes place with  
22 standardised questionnaires, interviews and physical examinations. It is  
23 intended to include 1,200 employees at 120 different workplaces. For analysis  
24 of the quality criteria, recommendations of the COSMIN checklist (COnsensus-  
25 based Standards for the selection of health Measurement INstruments) will be  
26 taken into account.

### 27 Ethics and dissemination:

28 The study was planned and conducted in accordance with the German Medical  
29 Professional Code and the Helsinki Declaration as well as the German Federal  
30 Data Protection Act. The design of the study was approved by Ethics  
31 Committees. We intend to publish the validated KIMs in 2018. Results will be

1 published in peer-reviewed journals, presented at international meetings and  
2 disseminated to actual users for practical application.  
3

## 4 **Keywords**

5 Risk assessment, Key Indicator Method, Work-related musculoskeletal  
6 disorders, OCRA, NIOSH Lifting Equation, Strain Index  
7

## 8 **Strengths and limitations of this study**

- 9 • This research project will provide a scientific substantiation and – if  
10 necessary according to the results of the study – modification of  
11 standardised methods to assess physical workloads at a screening level.
- 12 • With the help of these KIMs, the full range of physical workloads  
13 (excluding exposures due to hand-transmitted and whole-body vibration)  
14 could be assessed by occupational health and safety stakeholders.
- 15 • Knowledge about the correlation between work-related factors and MSDs  
16 will be advanced.
- 17 • The study is limited by the cross-sectional design, which is not suitable  
18 to assess the causal relationship between variables but only  
19 associations.  
20  
21

# 1 Main text

## 2 INTRODUCTION

### 3 General background

4 Work-related musculoskeletal disorders (WRMSDs) have been recognised for  
5 many decades[1, 2]. Disorders often mentioned in the literature include low  
6 back pain and intervertebral disc diseases[3], epicondylitis[4] and carpal tunnel  
7 syndrome[5]. Hard physical work may also lead to high cardiovascular strain  
8 and may increase the mortality risk of ischaemic heart disease in individuals  
9 with a low or moderate fitness level[6].

10 According to the European Council Directive 89 / 391 / EEC of 12 June 1989 on  
11 the introduction of measures to encourage improvements in the safety and  
12 health of workers at work, the employer must perform an assessment of the  
13 risks to safety and health at work, including those to which specific groups of  
14 workers are exposed[7]. One year later, a further European Council Directive  
15 90 / 269 / EEC “manual handling of loads” of 29 May 1990 was published  
16 addressing the minimum health and safety requirements for the manual  
17 handling of loads where there is a risk particularly of back injury to workers[8].

18 To assess the risk of WRMSDs, a number of assessment methods have been  
19 developed[9].

20 The risk assessment of physical workloads is a basic necessity to derive  
21 purposeful prevention measures. Beside the legal requirements mentioned  
22 above, ergonomic interventions usually have financial merits. Within a  
23 systematic review, from a company perspective strong evidence was found in  
24 support of the financial merits of ergonomic interventions in the manufacturing  
25 and warehousing sector, moderate evidence in the administrative support and  
26 health care sectors, and limited evidence in the transportation sector [10].

### 27 Previous development and validation of the KIMs

28 In Germany, the release of the two European Council Directives triggered the  
29 development of “Key Indicator Methods” (KIMs), see Figure 1. The KIMs were  
30 developed for risk assessment at the screening level in the case of physical  
31  
32

1 workloads. Potential users include occupational safety and health stakeholders  
2 and industrial engineers in companies as well as ergonomists, occupational  
3 health physicians, employers and employees associations, and insurance  
4 companies or research facilities. Three different KIM worksheets, one for  
5 Lifting, Holding, Carrying loads (KIM-LHC), one for Pulling and Pushing loads  
6 (KIM-PP) and one for Manual Handling Operations (KIM-MHO), are available so  
7 far. These methods were developed by the Federal Institute for Occupational  
8 Safety and Health (BAuA) in close collaboration with practitioners, safety  
9 representatives, occupational health physicians, and the “Länderausschuss für  
10 Arbeitsschutz und Sicherheitstechnik” (Federal Committee of the States for  
11 Occupational Safety and Health)[11, 12, 13]. Briefly, work characteristics such  
12 as force, frequency and duration, and general working conditions are assessed  
13 by means of the KIM, and a score is calculated to summarise the work-  
14 associated risk for adverse health outcomes, e.g. musculoskeletal symptoms.  
15 To illustrate the result, the score is transformed into a traffic light scale  
16 indicating a low exposure situation where physical overload is unlikely to occur  
17 (= green), situations with slightly increased (= greenish yellow) and  
18 substantially increased (= yellow) exposure, up to a high exposure situation  
19 where physical overload is likely to occur and a redesign of the workplace is  
20 probably necessary (= red)[14]. The current existing methods can be  
21 downloaded from the homepage of BAuA[15]. The three existing KIMs deal with  
22 manual handling of loads and repetitive manual handling operations. Further  
23 aspects of physical workloads, such as awkward body posture, whole-body  
24 forces and body movement have not or not sufficiently been included in this  
25 method inventory yet. In order to fill this gap, drafts of three supplemental  
26 methods were developed. Further developments are necessary and a revision  
27 of the three existing methods is required, so that all six methods are  
28 compatible. In addition, the development of a method for the assessment of  
29 mixed physical workloads is planned.

30

## 1 Preliminary work – development of new KIM drafts

2 The preliminary work during the last decades mentioned above (see Figure 1),  
3 was complemented by an additional search of peer-reviewed articles and grey  
4 literature predominantly in German and English. Various other methods for the  
5 assessment of working conditions associated with physical workloads were  
6 analysed systematically. The various methods included on the one hand a large  
7 number of work characteristics considered to be related to health outcomes,  
8 and on the other hand a large number of different body regions, symptoms and  
9 diseases which could be affected by these work characteristics. There is only  
10 low evidence of a “cause and effect model” or even a “dose response  
11 relationship” with certainty between most physical workloads and MSDs. In the  
12 published studies or methods, the selection of the observed characteristics  
13 varied significantly. Unfortunately, details about the selection of the parameters  
14 were often not indicated in the publications available and many questions  
15 remain, e.g. questions about the deduction or the combination of the  
16 parameters to be assessed for description of work-related risks. In addition,  
17 only a small number of methods assessing biomechanical exposures in  
18 occupational settings have been tested in a systematic manner for validity,  
19 reliability, or other aspects related to their practical use[9].

20 The development of the new KIM-drafts was based on a comprehensive and  
21 critical literature review of the methods mentioned above. This knowledge was  
22 combined with interviews about typical kinds of exposures and exposure-  
23 structures of physical workloads, involving scientists, supervisors of state  
24 agencies and professional associations, occupational physicians, occupational  
25 health and safety officers, and managers from companies in various industries..  
26 Finally, the drafts of three new KIMs (whole body forces, awkward postures,  
27 and body movement) were available for validation within the present study.

28

## 29 METHODS AND ANALYSIS

### 30 Aim, design and setting

31 In this study protocol, the concept for development and validation of the newly  
32 developed and redesigned KIMs is presented. It is part of a joint project

1 (MEGAPHYS – Mehrstufige Gefährdungsanalyse physischer Belastungen am  
2 Arbeitsplatz [Multilevel risk assessment of physical workloads]). The distribution  
3 of the responsibility for the recruitment and documentation of the workplaces  
4 and the realisation of the interviews of further partners in the joint project are  
5 described in the “Funding” and “Acknowledgements” sections. General aims,  
6 definition of the six types of physical workloads used and the background of the  
7 joint project MEGAPHYS have been described previously[16].

8 The aim of the study protocol presented here is to provide the concept of how  
9 to validate the revised versions of the three existing KIMs (KIM LHC, KIM PP,  
10 KIM MHO) and the draft versions of the three new KIMs for whole body forces,  
11 awkward postures, and body movement (KIM ABP, KIM BF, KIM BM) in order  
12 to provide validated risk assessment methods for these six types of physical  
13 workloads. Furthermore, a draft of an additional KIM for the assessment of  
14 mixed physical workloads, including relevant indicators of the six specific KIMs,  
15 is also planned (see Tables 1 and 2). The “combined KIM” will be developed  
16 during the study based on the Key Indicators of the six KIMs. Different  
17 mathematical models will be tested and enhanced iteratively. Since this method  
18 is not fixed at the beginning of the validation study, we will only be able to  
19 disseminate a draft of a combined method and not a fully validated method at  
20 the end of this project.

21 A number of methods for the risk assessment of physical workload already  
22 exist[9]. These methods are of very different extents and qualities, from simple  
23 checklists to comprehensive methods with extensive testing of different quality  
24 criteria (e.g. tested in several cross-sectional studies and longitudinal studies).  
25 A disadvantage of these methods is that they are often only “single solutions”.  
26 That means, they focus on one type of physical workload (e.g. load handling)  
27 and the different methods have different risk scales. If someone wants to  
28 assess several different types of physical workload at a workplace, he or she  
29 must use different methods and obtain different results (e.g. a risk index at  
30 NIOSH Lifting Equation[17], or risk categories at Rapid Entire Body  
31 Assessment – REBA[18]). The reason for this project is to have one system  
32 with a uniform risk concept and cover all the main types of physical workloads.  
33 The division into the six different types of physical workloads presented here

1 has mainly pragmatic reasons: These are distinguishable types of physical workloads which can be identified and assessed by the practical user.

2 The main objective to be considered is the association between physical workloads, as assessed by means of the scores of the KIMs, and the frequency of musculoskeletal symptoms and other outcomes within the exposed workers in terms of discriminative capacity of the six KIMs or the newly drafted combined KIM.

3 The validation of KIM uses a cross-sectional design and a mixed-method approach. For the determination of criterion validity, a cross-sectional study among 1,200 employees at approx. 120 different workplaces will be carried out. Workplace analyses will be done by direct observations and assessments using the KIMs, interviews of employees and managers, workplace measurements (e.g. noise, climate) and video recordings. Exposures are analysed and documented by members of the study team. The workplace analyses will also be used for the determination of face validity, reliability, convergent validity, criterion validity and further aspects of utility.

4 Setting of the study will be workplaces in voluntarily participating companies of different sizes and branches (including e.g. industry, handicraft, health care) in Germany.

### 21 **Characteristics of participants**

22 For the analysis of criterion validity, male and female employees, 19 to 65 years of age, at workplaces with different types and levels of physical workloads will be recruited, who have worked at the workplaces considered for at least three months and are proficient in the German language. For each type of physical workload (total of six types: LHC, PP, MHO, BF, ABP, BM) and for each of four exposure levels as rated by experts beforehand (low, slightly increased, substantially increased, and high), approximately 40 to 50 employees will be recruited (assuming predominantly uniform exposures in each group). The aim is to cover all employees of the selected workplaces. Employees participate in the study voluntarily. The employer makes participation in the study possible for the employees within the working time.

1  
2  
3 1 Only if more than 20 volunteers are engaged in the same workplace, the  
4 2 participants will be selected randomly. The study population can be calculated  
5 3 as follows: 6 types of physical workloads x 4 exposure levels x 50 subjects per  
6 4 type of physical workload and exposure level = 1,200 subjects. Assuming, that  
7 5 at each workplace an average of 10 employees can be recruited, 120  
8 6 workplaces need to be observed and documented. It is intended to analyse  
9 7 about 5 workplaces per type of physical workload and exposure level.  
10 8 Approximately 10 employees per workplace will be interviewed by ergonomists,  
11 9 and interviewed and examined by physicians.

12 10 The data gathered during observation and documentation of the 120  
13 11 workplaces will also be used for the determination of convergent validity,  
14 12 reliability and further aspects of utility. For the determination of interrater-  
15 13 reliability, 12 users of the KIMs are needed, to represent future users. Typical  
16 14 users of these kinds of assessment methods ideally are occupational health  
17 15 and safety stakeholders or industrial engineers in the companies. From these  
18 16 12 users, six pairs will be formed (one pair per type of physical workload), each  
19 17 observing 20 workplaces. This will result in 120 double ratings. No specific  
20 18 skills will be required for this tests, but the users will get a standardised  
21 19 introduction in the methods. The content of this introduction will be used later  
22 20 as framework for a guideline which will be disseminated with the method.  
23 21

## 22 **Working hypotheses**

23 The working hypotheses (WH) include the examination of different quality  
24 criteria of the KIMs:

- 25 • WH 1: The KIMs are an adequate reflection of the construct to be  
26 measured (face validity).
- 27 • WH 2: At the completion of the KIMs, no relevant deviations occur  
28 between different users assessing the same workplaces (reliability).
- 29 • WH 3: Assessing workplaces using the KIMs and other screening  
30 methods measuring the same type of physical workload will result in no  
31 relevant differences (convergent validity).

- 60
- WH 4: It is assumed, that employees at workplaces with high physical workloads show adverse health-related outcomes (e.g. musculoskeletal symptoms) more frequently than non-exposed workers. It is assumed, that high risk scores derived in the assessment of workplaces with the KIMs are associated with a high prevalence of musculoskeletal symptoms and disorders (criterion validity or content validity regarding hypotheses testing).

The selection of the quality criteria described in the working hypotheses are derived from a systematic evaluation of observational methods assessing biomechanical exposures at work[9]. For the analysis of the quality criteria, the recommendations of the COSMIN checklist (COnsensus-based Standards for the selection of health Measurement INstruments) will be taken into account[19]. The reporting of the results of this observational study will also consider the recommendations of STROBE (Strengthening The Reporting of OBservational studies in Epidemiology)[20].

## **Instruments and Methods**

The instruments and methods for the assessment of exposures and outcomes (i.e. questionnaire, medical diagnostic tool, assessment of working conditions) used in this survey have been used in a similar form in other studies by several authors. The authors of the present study used them for the assessment of musculoskeletal symptoms in office workers[21] and in a former validation study of the KIM MHO[22, 23].

### **1) Assessment of exposures:**

- Ergonomic work procedure analysis and assessment of technical procedures for the documentation of working conditions.

### **2) Application of the KIMs:**

- Application of the six KIMs based on the exposure assessment.

### **3) Assessment of health outcomes:**

- Standardised questionnaire for a survey among the employees.
- Medical diagnostic tool for the physical examination of the employees.

### *Ergonomic work procedure analysis for the assessment of exposures*

The basis for the evaluation of the workplaces is an ergonomic work procedure analysis with detailed assessment of exposures during the shift. An a priori defined set of items of a complex workplace analysis was developed. Results are recorded in a large modular document for a detailed description of the work tasks and the workplace. A workplace typically consists of a number of different work tasks. Duration and frequency of all work tasks are documented in a way that the KIMs, as well as further screening methods chosen for the testing of convergent validity, can be completed. The ergonomic work procedure analysis covers in principle all relevant objective characteristics that result from the type of work and the working conditions. Individual characteristics during work execution, random disruption of the workflow or unusual conditions will not be considered. Principal components of the work procedure analysis are:

- 1) Metadata of the workplace, such as: name and type of activity, precise list of work tasks, professional qualification requirements, position of employees, complexity of the activity, number of employees at the workplace, gender and age distribution, shift system, typical working time, predetermination of the work task;
- 2) Number and type of work task and for every work task detailed information, for example: about temporal distribution of this work task during the shift, determination of type of work (e.g. load handling, applying force, body posture, joint positions); and
- 3) Basic description of other relevant exposures, such as: noise level, lighting, vibration, hazardous materials.

### *Application of the Key Indicator Methods (KIMs)*

The application and validation of the KIMs are the central goals of this research project and will be completed based on the ergonomic work procedure analysis. The KIMs contain an objective requirement and description of exposures and identify potential threats to physical overload. The KIMs include job characteristics and their interaction. The key indicators are classified in different scales. The scales correspond to conditions in practice and range from a

1 minimum to maximum, or optimum to poor. The classification of these scales  
2 indicates bottlenecks for each category and key indicator. By multiplying the  
3 scale value of the daily duration and frequency of activity with the sum of the  
4 other scale scores, a total value can be calculated. This calculated sum score  
5 can be allocated to an exposure level and one of four risk categories, an  
6 approach already used in existing KIMs[14]. The four risk categories reflect the  
7 increase in the probability of physical overload and correspondingly the  
8 increase in frequency of adverse health effects related to the given physical  
9 workload from low (reference group) to high load situations (see above, section  
10 “Previous development and validation of the KIMs”).

11 An overview of the KIMs, including a brief description of the types of physical  
12 workloads, the key indicators considered and some examples of typical work  
13 tasks is provided for the already existing KIMs in Table 1 and for the KIMs  
14 under development in Table 2. The revisions of the already existing KIMs  
15 include small changes (e.g. wording) to harmonise the six KIMs and major  
16 changes, such as the modification of the time rating and the implementation of  
17 new aspects (e.g. load handling conditions and location of the load during  
18 LHC).

19

1 Table 1: Existing KIMs (to be revised)

Acronym	Focus of this Key Indicator Method (KIM)	Key Indicators to be considered in this KIM in the revised version	Examples
KIM LHC	Manual Lifting, Holding and Carrying loads $\geq 3$ kg	<ul style="list-style-type: none"> <li>• Daily frequency</li> <li>• Effective load weight*</li> <li>• Load handling conditions / location of the load**</li> <li>• Body posture</li> <li>• Unfavourable working conditions*</li> <li>• Work organisation / distribution of this type of physical workload during the shift**</li> </ul>	Loading / unloading of bags, sorting packages, loading of equipment without lifting aids, picking
KIM PP	Manual Pushing and Pulling of loads with trucks and monorails	<ul style="list-style-type: none"> <li>• Daily duration and distance*</li> <li>• Load weight / transport device*</li> <li>• Driveway conditions**</li> <li>• Properties of transport device**</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this type of physical workload during the shift*</li> </ul>	Postal service with cart, picking with containers, waste disposal
KIM MHO	Manual Handling Operations: Work tasks with uniform, repetitive motion and predominantly lower force expenses of the upper extremities during MHO	<ul style="list-style-type: none"> <li>• Daily duration*</li> <li>• Type, duration, and frequency of the executing force*</li> <li>• Force transfer and gripping conditions</li> <li>• Hand-arm posture during manual work processes</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this type of physical workload during the shift</li> </ul>	Assembly activities (e.g. installation of electrical appliances), sorting, cutting, cashiering, manually controlling, pipetting, microscopy, joining, turning, cutting, moving, wrapping
<p>* Compared to the existing KIM, this Key Indicator is modified considerably in the revised version</p> <p>** Compared to the existing KIM, this Key Indicator is added in the revised version</p>			

2

1 Table 2: New KIMs (to be developed)

Acronym	Focus of this Key Indicator Method (KIM)	Key Indicators to be considered in this KIM	Examples
KIM BF	Whole Body Forces with mostly stationary force application.	<ul style="list-style-type: none"> <li>• Daily duration</li> <li>• Type, duration, and frequency of the executing force</li> <li>• Symmetry of the application of force</li> <li>• Body posture</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this type of physical workload during the shift</li> </ul>	Working with winches, work with levers, working with pneumatic hammers, working with chainsaws
KIM ABP	Awkward Body Postures including any strenuous postures, which are predestinated by the work process and are long lasting	<ul style="list-style-type: none"> <li>• Duration and temporal distribution of different trunk postures</li> <li>• Duration and temporal distribution of sitting / walking / standing during the day</li> <li>• Duration and temporal distribution of hands above shoulder and far from body</li> <li>• Duration and temporal distribution of kneeling, squatting</li> <li>• Unfavourable working conditions</li> </ul>	Steel fixing (concrete), manual welding, ceiling mounting, work at the microscope, working inside of tanks, microsurgery
KIM BM	Body Movements to a place of work or in a work area, which will be assessed independently of applying force	<ul style="list-style-type: none"> <li>• Body movement and eventually carried load</li> <li>• Location of the load centre</li> <li>• Body movement when driving with transport device</li> <li>• Driveway conditions (if work task includes driving)</li> <li>• Unfavourable working conditions</li> <li>• Work organisation / distribution of this type of physical workload during the shift</li> </ul>	Climbing tower cranes, control inspections in channels, maintenance on furnaces
KIM ME	Mixed Exposures: combination of the exposures of a shift	<ul style="list-style-type: none"> <li>• Covers the key indicators of the 6 KIMs mentioned above</li> </ul>	Work places with different exposures during the shift

2

### 1 *Standardised questionnaire for the assessment of health outcomes*

2 The employees' questionnaire (conducted in interview) is divided into 4 parts:

- 3 1. Personal details including sociodemographic data (e.g. age, gender,  
4 years on the job, leisure time activities), general information about  
5 current and former occupational activities (e.g. type and amount of  
6 physical workload, time pressure, shift work, working posture);
- 7 2. Subjective assessments of the exposure in the workplace (questionnaire  
8 of the subjective estimation of exposures – FEBA[24]);
- 9 3. Other psychosocial aspects (e.g. job satisfaction, social support,  
10 commitment; extract from the COpenhagen PSYchOSocial Questionnaire  
11 - COPSOQ[25, 26]); and
- 12 4. Subjective perceived exertion of physical workload (Borg RPE scale[27]).

### 13 *Medical diagnostic tool for the assessment of health outcomes*

14 The documentation of the medical interviews is based on the Standardised  
15 Nordic questionnaires for the analysis of musculoskeletal symptoms[28, 29]. To  
16 substantiate the statements of the employees about the musculoskeletal  
17 symptoms in the interviews, a physical examination is performed after the  
18 interview. In order to derive specific tentative medical diagnoses, a list of  
19 standard diagnoses of musculoskeletal disorders is considered. The medical  
20 diagnostic tool used in the present study was derived from a SALTSA study[30]  
21 and supplemented by a multi-stage diagnosis[31] and further examination  
22 techniques[32]. The diagnostic tool consists of a documentation sheet and a  
23 reference sheet. The documentation sheet is divided into three parts. Part A is  
24 a general survey to document painful or symptomatic body regions. Part B  
25 deals with specific examination techniques to be carried out if pain or  
26 symptoms in specific regions were documented in part A. According to these  
27 results and with assistance of a reference sheet, tentative diagnoses can be  
28 assigned using a list of diagnoses in part C.

1  
2  
3 1 These are:

4 2 Diseases of the upper extremities

- 5  
6 3 • Cervical / cervicocephal syndrome  
7  
8 4 • Cervicobrachial syndrome  
9  
10 5 • Rotator cuff syndrome, adhesive capsulitis of shoulder  
11  
12 6 • Medial and lateral epicondylitis  
13  
14 7 • Flexor / extensor peritendinitis / tendosynovitis of forearm/wrist region  
15  
16 8 • Carpal tunnel syndrome  
17  
18 9 • Osteoarthritis of the joints of the distal upper extremities

19 10 Disorders of the lower back

- 20  
21 11 • Low back pain / lumbago  
22  
23 12 • Lumbar facet syndrome – pseudo-radicular syndrome  
24  
25 13 • Lumbar radicular syndrome

26 14 Disease of the lower extremities

- 27  
28 15 • Hip osteoarthritis  
29  
30 16 • Knee osteoarthritis (including chondromalacia patellae)  
31  
32 17 • Meniscus lesion  
33  
34 18 • Static insufficiency of foot  
35  
36 19 • Varicosis of the leg veins

37 20 Further relevant conditions not included in this list are also recorded.  
38  
39 21

## 40 41 22 **Data Analysis Plan**

42 23 *Analysis of WH 1 (face validity)*

43  
44  
45 24 Face validity was derived from preliminary work and a feasibility study, which  
46  
47 25 was done in preparation prior to the main study[33]. For the determination of  
48  
49 26 face validity, no statistic procedures are used. As mentioned above, the six  
50  
51 27 KIMs were developed based on our own experiences and research during the  
52  
53 28 last decades, including an extensive search of peer-reviewed scientific articles  
54  
55 29 and other grey literature concerned with methods for the assessment of working  
56  
57 30 conditions associated with physical workloads. In 2015, the feasibility of the six  
58  
59 31 KIMs were field-tested at 114 workplaces in 40 different companies. At each  
60

1 workplace, the KIMs were completed and discussed with the respective  
2 occupational health and safety stakeholders in the companies, and developed  
3 further iteratively. Over-all, the KIM forms were completed 615 times during this  
4 process. According to these field-tests, the results seemed to be plausible to  
5 the stakeholders involved and all relevant aspects seemed to be  
6 implemented[33]. The results of this feasibility study were integrated in modified  
7 drafts of the KIMs which are basis for the scientific validation described in the  
8 following research goals and chapters.

### 9 10 *Analysis of WH 2 (reliability)*

11 It will be analysed, whether relevant deviations between different users  
12 assessing the same workplaces occur. The reliability will be determined by  
13 examining the independence of results assessed by different individuals  
14 (occupational health and safety stakeholders). Descriptive statistics (mean,  
15 median, variance, range) will be used to illustrate the distribution of different  
16 workplace assessments of the involved experts. Interrater-reliability for multiple  
17 raters will be analysed using standard video sequences of typical workplaces  
18 for risk assessment, and rating these videos by a group of selected experts  
19 under standardised conditions[34].

### 20 21 *Analysis of WH 3 (convergent validity)*

22 It will be analysed, whether relevant differences occur during assessment of  
23 workplaces with the KIMs and with other screening methods measuring the  
24 same type of physical workload. Data basis for the determination of the  
25 convergent validity are descriptions of the 120 workplaces gathered in the  
26 cross-sectional study. During the selection of the workplaces to be included in  
27 the study, an equal distribution of the six types of physical workloads and the  
28 four exposure levels will be taken into account. It is assumed that an average of  
29 five work tasks can be analysed at any workplace. Thus, around 600 work task  
30 descriptions will be available, 100 descriptions per type of physical workload.  
31 Each KIM provides a score of 1 point to about 200 points (theoretically, point  
32 values > 1,000 are possible, however, these values are unlikely to appear  
33 under real conditions). If the respective comparison method also produces a

1 score, correlation analyses will be performed[35]. The correlation coefficient  
2 and the mean value will be taken into account. If the comparison method does  
3 not produce a score (for example, differs only dichotomously between "green"  
4 and "red), Cohen's kappa[36] is calculated using the exposure levels of the  
5 KIMs. For the six KIMs expressing six types of physical workloads, other  
6 existing methods were selected for comparison which meet as many of the  
7 criteria as possible below:

- 8 • Description of quality criteria,
- 9 • Large degree of dissemination,
- 10 • Plausible and comprehensible model, and
- 11 • Matching ability with the concept presented here.

12 At the time of the adoption of this study protocol, among others the following  
13 methods are suggested for the examination of convergent validity: Rapid Entire  
14 Body Assessment – REBA[18], Assessment technique for postural loading on  
15 the upper body – LUBA[37], Assessment of Exposure to Occupational  
16 Repetitive Actions of the Upper Limbs – OCRA[38], Threshold Limit Value for  
17 Mono-Tasks Handwork Hand Activity Level – HAL[39], Strain-Index[40], NIOSH  
18 Lifting Equation[17], Group-Evaluation-Tables[41], Garg-Procedure[42],  
19 Procedure for the assessment of workloads – BAB[43] and the former versions  
20 of the KIMs[11,12,13], as these fit more or less with one or more of the six  
21 types of physical workload (LHC, PP, MHO, BF, ABP or BM) and therefore to  
22 one or more of the six newly developed and redesigned KIMs.

#### 23 *Analysis of WH 4 (criterion validity or content validity regarding hypotheses* 24 *testing)*

25 It will be analysed, whether employees at workplaces with high physical  
26 workloads show adverse health-related outcomes (e.g. musculoskeletal  
27 symptoms) more frequently than non-exposed workers considering relevant  
28 confounders such as age, gender, constitution or disposition. It is assumed,  
29 that high scores derived in the assessment of workplaces with the KIMs are  
30 associated with a high frequency of musculoskeletal symptoms in exposed  
31

1 workers. Accordingly, low scores in the KIMs resulting at workplaces with low  
2 physical workloads are associated with a low frequency of musculoskeletal  
3 symptoms in workers. For each type of physical workload and each KIM the  
4 (main) outcome region(s) considered vary. The approximate impact of physical  
5 workloads and outcomes is described schematically in Figure 2.

6 Effect estimates for dichotomous outcomes (prevalence of symptoms) are  
7 prevalence ratios with 95 % confidence intervals per type of physical workload  
8 and exposure level, as determined by the KIMs. Effect estimates for continuous  
9 outcomes (e.g perceived exertion) are beta-estimators (increment) with 95 %  
10 confidence intervals per type of physical workload and exposure level, as  
11 determined by the KIMs. The lowest exposure level is regarded as the  
12 reference category (internal control group). The increments are estimated using  
13 linear regression models (IBM-SPSS-Statistics procedure Genlin) under  
14 consideration of confounders (at least: age, sex, BMI, and body height). For  
15 each type of physical workload (each KIM), the following models are calculated:

- 16 • Minimally adjusted models (age, gender),
- 17 • Moderately adjusted models (age, sex, BMI, body height and other  
18 types of physical exposures), and
- 19 • Maximally adjusted models (age, sex, BMI, body height, other types of  
20 physical workloads, other occupational exposures and other  
21 confounders, see Table 3).

22 Primarily, the moderately adjusted models will be interpreted. As far as possible,  
23 based on the regression models, post hoc assessments of prevalences of the  
24 outcomes for each type of physical workload will be conducted. Subjects are  
25 excluded from the analyses, if missing data in the different body regions occur.  
26 Sensitivity analyses are intended regarding regional distribution of the  
27 workplaces, company characteristics (size, branche etc.) and gender. For an  
28 overview of the outcomes, exposures, predictors and potential confounders,  
29 see Table 3. The analysis of effect modifiers is not included in this study.

1 *Table 3: Description of outcomes, exposures, predictors and potential confounders*

Outcomes	Exposures	Predictors	Potential confounders
<p>1) Prevalence of musculoskeletal symptoms (7-day and 12-month prevalence) in the following body regions:</p> <ul style="list-style-type: none"> <li>• Neck</li> <li>• Shoulder</li> <li>• Elbow / Lower arm</li> <li>• Hand / Wrist</li> <li>• Upper Back</li> <li>• Lower Back</li> <li>• Hip / Thigh</li> <li>• Knee</li> <li>• Ankle joint / Feet</li> </ul> <p>2) Tentative medical diagnoses</p> <p>3) Exposure reaction of the cardiovascular system described by perceived exertion (Borg RPE scale)</p>	<p>Six types of physical workload:</p> <ul style="list-style-type: none"> <li>• Manual lifting, holding and carrying of loads (LHC)</li> <li>• Manual pulling and pushing of loads (PP)</li> <li>• Manual handling operations (MHO)</li> <li>• Whole body forces (BF)</li> <li>• Awkward body postures (ABP)</li> <li>• Body movement (BM)</li> </ul>	<p>Predictors are the exposure levels of the KIMs:</p> <ul style="list-style-type: none"> <li>• Level 1 (reference category): low exposure, physical overload is unlikely to occur</li> <li>• Level 2: slightly increased exposure, physical overload possible for particular groups of employees</li> <li>• Level 3: substantially increased exposure, physical overload possible</li> <li>• Level 4: high exposure, physical overload is likely to occur</li> </ul>	<ul style="list-style-type: none"> <li>• Sex (split variable)</li> <li>• Age</li> <li>• Body-Mass-Index (BMI)</li> <li>• Body height</li> <li>• Other types of physical workload*</li> <li>• Other occupational exposures (e.g. noise, vibrations)</li> <li>• Job satisfaction</li> <li>• Quantitative demands</li> <li>• Cognitive demands</li> <li>• Workplace insecurity</li> <li>• Influence at work</li> <li>• Social support</li> <li>• Social relations</li> </ul>
<p>* If e.g. tested for the exposure LHC, the other exposures, which might occur during the shift (PP, MHO, BF, ABP, BM) are considered as confounders. For a rough overview, see Figure 2.</p>			

## 1 **Sample Size calculation**

2 For power or sample size calculation the EpiManager-Software[44] and  
3 G\*Power[45] were used.

### 4 5 *Power for determination of reliability*

6 For the determination of reliability (WH 2), 12 users of the KIMs are needed, in  
7 order to represent future potential users. From these 12 users six pairs will be  
8 formed, each observing 20 workplaces. This will result in 120 double ratings. As  
9 statistical measures, correlation coefficients are calculated and comparisons of  
10 mean values are carried out. The assessment of conformity is based on the  
11 following categories: values  $\leq 0.3$  = small;  $> 0.3$  to  $< 0.5$  = low;  $0.5$  to  $< 0.7$  =  
12 good;  $\geq 0.7$  = high correlation.

13 In order to demonstrate a correlation (correlation coefficient,  $r$ ) of 0.7 (alpha  
14 0.05 and beta 0.8), about 15 double observations would be necessary. For a  
15 correlation of 0.8, 10 double observations would be necessary. The target of 20  
16 double observations per type of physical workload should ensure an adequate  
17 study power.

### 18 19 *Power for determination of convergent validity*

20 For the determination of convergent validity (WH 3) workplaces will be  
21 assessed by scientists experienced in ergonomics using the KIMs and further  
22 screening methods assessing the same type of physical workload. A correlation  
23 coefficient between the KIM and an alternative screening method of  $r = 0.5$  or  
24 higher is considered to be an adequate correlation[35]. To show that two  
25 methods correlate at least with an  $r$  of 0.5 or higher ( $H_1: r > 0.5$  vs.  $H_0: r = 0$ ),  
26 56 sets of recorded data are required for each of the six KIMs. If only 30 sets of  
27 recorded data per process could be evaluated, it can be shown that the two  
28 methods correlate with an  $r$  of about 0.8 or higher ( $H_1: r > 0.8$  vs.  $H_0: r = 0$ ,  
29 alpha  $< 0.05$ , beta 0.8). If the comparison method does not produce a score but  
30 only categories, Cohen's kappa[36] is calculated. In this case, 100 data sets  
31 are needed to show statistically relevant correlations.

32

1 *Power for determination of criterion validity*

2 As described in WH 4, it is assumed, that employees at workplaces with high  
3 physical workloads show adverse health-related outcomes more frequently than  
4 non-exposed workers. The outcomes to be considered in this study are (Table  
5 4):

- 6 1) Prevalence of musculoskeletal symptoms (7-day and 12-month) in nine  
7 body regions (Figure 2),
- 8 2) Prevalence of tentative diagnoses, and
- 9 3) Perceived exertion (Borg RPE scale[27]).

10  
11 *Table 4: Expected outcomes according to exposure levels of the KIMs*

Exposure levels of the KIMs	1) Prevalence of musculoskeletal symptoms	2) Prevalence of tentative diagnoses	3) Perceived exertion (Borg RPE scale)
Low	Reference group	Reference group	Very light
Slightly increased	7-day prevalence increased	12-month prevalence hardly increased	Light
<b>Acceptance level</b>			
Substantially increased	7-day prevalence significantly increased (at least double)	12-month prevalence slightly increased	Somewhat hard
<b>Tolerance level</b>			
High	7-day prevalence significantly increased (at least triple)	12-month prevalence substantially increased	Very hard

12

13 *1) Power for the outcome "prevalence of musculoskeletal symptoms"*

14 The minimum size of study population (at least 40 to 50 subjects per exposure  
15 level, targeted in "characteristics of the participants in the study") is based on  
16 the power calculation. The 7-day prevalence of MSDs among males and  
17 females without physical workloads (office workers) was assessed in  
18 preliminary studies[21]. The 7-day prevalence of MSDs for women was  
19 between 30 % (cervical spine) and 5 % (hip, ankles) and for men between 20 %  
20 (cervical spine) and 5 % (ankles) or 2 % (hip). The 12-month prevalence of  
21 MSDs in men and women without physical workloads was significantly higher,  
22 from 50 % to 65 % (cervical spine) to 10 % (hip, ankle). Assuming an alpha  
23 error of 5 % and a beta error of 80 %, in a group size of 40 persons exposed

1 and 40 persons not exposed, and assuming a prevalence of 5 % in the  
2 reference group, a prevalence ratio of 6.5 is significantly increased. If the  
3 prevalence of MSDs in the reference group is 20 %, prevalence differences are  
4 detectable by a factor of 2.5. Prevalence differences of this amount between  
5 non-exposed (exposure level: low) and highly exposed employees (exposure  
6 level: high) were observed in the preliminary study mentioned above. It is  
7 therefore expected that variations in prevalence of factors of at least 2 to 6 will  
8 be detectable, when comparing the two highest exposure categories by KIM  
9 with the lowest exposure level (reference group).

### 10 11 2) *Power for the outcome “prevalence of tentative diagnoses”*

12 Due to the expected relatively low incidence of diagnoses in the working  
13 population, no statistically significant increase in the prevalence of tentative  
14 diagnoses is expected. However, an increasing trend with increasing physical  
15 workloads from exposure level “low” to exposure level “high” is expected.

### 16 17 3) *Power for the outcome “perceived exertion (Borg RPE scale)”*

18 The highest limitations in power calculation according to criterion variability  
19 result from dichotomous variables as described in the section above (power for  
20 the outcome “prevalence of musculoskeletal symptoms”). Therefore, the power  
21 of the study according to continuous variables (such as perceived exertion) is  
22 high due to the fact that 1,200 subjects will be included in this study.  
23 Considering the large number of subjects, small differences of continuous  
24 variables between risk category groups are detectable.

### 25 26 **Quality control and assurance**

27 The use of standardised and – if available and appropriate – already validated  
28 and/or evaluated screening methods as comparison or reference methods  
29 ensures high quality of work. All questionnaires will be completed during a face-  
30 to-face interview. The work-related physical examination will be performed by  
31 trained external physicians. A standardised procedure for physical examination  
32 is guaranteed by the specific standardised training of the physicians.

1 Remembering earlier symptoms in a retrospective period could involve a recall  
2 bias. In order to minimize the bias and to get a more detailed overview, we ask  
3 for the past 7-days prevalence and the 12-month prevalence of symptoms. In  
4 addition, a physical examination is carried out. The observation of these three  
5 outcomes together might reduce the recall bias. According to the selection  
6 criteria, only workers are included who are actually working at the workplaces.  
7 Workers with sickness absence cannot be considered in the recruitment. This  
8 could imply a healthy worker effect. The total number of workers at a workplace  
9 is requested of the companies and the number of sick leave days in the last 12  
10 months is enquired of the volunteers. The information is considered in sub-  
11 analyses to get an impression of the extent of this issue.

### 13 **What this study adds**

14 In this study, new KIMs for practical risk assessment of physical workloads are  
15 developed and these new KIMs, as well as the already existing KIMs, will be  
16 validated. The KIMs are a modular tool kit of practical screening methods for  
17 assessing the risk factors associated with work-related musculoskeletal  
18 disorders. In addition, the study will increase the knowledge concerning the  
19 correlation between specific MSDs and characteristics of physical workloads.  
20 With this knowledge, a better classification of occupational hazards with regard  
21 to MSDs will be available in future. This may lead to more specific prevention  
22 strategies.

## 24 **ETHICS AND DISSEMINATION**

### 25 **Ethics approval and consent to participate**

26 The study was planned and conducted in accordance with the German Medical  
27 Professional Code and the Helsinki Declaration of 2013[46], as well as the  
28 German Federal Data Protection Act[47].

29 The design of the study was examined by the Ethics Committee of the  
30 Technical University Darmstadt. The protocol achieved a positive vote  
31 (approval no. EK15/2015 2015-09-22 as supplement to EK2/2013 2013-07-04)  
32 and the Ethics Committee of the Medical Faculty of the University of Tübingen

1 (004/2016BO2). The study was started after the Ethics Committees gave their  
2 written and unrestricted approval.

3 Employees participate in the study voluntarily. They can end their participation  
4 at any time without reason and without negative consequences, e.g. for their  
5 job. Written informed consent for participation is obtained before the survey.  
6 Employees receive written and verbal information about the main features of  
7 the study as well as about potential benefits for their health and their  
8 contribution to the common public welfare. If they accept the conditions of the  
9 study and their participation, they document their consent with their signature. A  
10 copy of this statement is intended to be kept by the employee for later  
11 reference or cancellation of participation. All original documents are treated  
12 according to the German Federal Data Protection Act. A comprehensive data  
13 protection concept was approved by the Data Protection Officer of the BAuA.  
14

### 15 **Timeframe of the study and dissemination of results**

16 The study team started the planning of this project in 2012. The data collection  
17 for the cross-sectional study then started in spring of 2016 and will end in  
18 summer 2017. Description and analysis of the data will be done in 2017. It is  
19 intended to present the approved or revised KIMs to the public in 2018. Results  
20 will be published in peer-reviewed journals, presented at international meetings  
21 and disseminated to actual users for practical application. Potential users  
22 include occupational safety and health stakeholders in companies, industrial  
23 engineers, ergonomists, occupational health physicians, employers and  
24 employees associations, and insurance companies or research facilities.  
25

### 26 **Acknowledgements**

27 The definitions of six types of physical workloads as well as the underlying  
28 theoretical concept of risk assessment were developed within a consensual  
29 process involving all MEGAPHYS partners. All authors of this manuscript are  
30 MEGAPHYS partners of BAuA. Further MEGAPHYS partners are the Institute  
31 for Occupational Safety and Health of the German Social Accident Insurance  
32 (IFA), the Institute of Ergonomics at the Darmstadt University of Technology

1 (IAD) and the Leibniz Research Centre for Working Environment and Human  
2 Factors (IfADo). BAuA and IFA are responsible for the recruitment of 50 % of  
3 the workplaces each. IFA contributes to the documentation of all 120  
4 workplaces. ASER with BAuA, and IAD are each responsible for the  
5 documentation of 50 % of the workplaces and the execution of 50 % of the  
6 described interviews. The physical examinations of the employees are  
7 performed by trained physicians of the Kern Medical Engineering GmbH (KME),  
8 Frankfurt, in cooperation with Prof. Rieger, head of the Institute of Occupational  
9 and Social Medicine and Health Services Research, University Hospital of  
10 Tuebingen. The authors thank Dr. Paul Kahle for the English language check.  
11

### 12 **Competing interests**

13 The authors declare that they have no competing interests.  
14

### 15 **Funding**

16 The (further) development and validation of the KIMs is part of a joint project  
17 (MEGAPHYS – Mehrstufige Gefährdungsanalyse physischer Belastungen am  
18 Arbeitsplatz [Multilevel risk assessment of physical workloads]) funded by the  
19 Federal Institute for Occupational Safety and Health (BAuA) and the German  
20 Social Accident Insurance (DGUV). Project reference numbers are F2333  
21 (BAuA) and FF-FP0358 (DGUV).  
22

### 23 **Authors' contributions**

24 All authors were involved in the conception and design of the study, and the  
25 preparation of this manuscript. US developed the first drafts of the KIMs and  
26 initiated this study. AK and FL concretized the salient content points of this  
27 protocol, such as selection of validation criteria and power calculation. AK had  
28 the lead management in preparation of the study protocol. US, AK, PS, HG, AS,  
29 BH, MS and FB form the development team of the new KIMs. All Authors were  
30 closely involved in the planning and development of the study design and

1 preparing the study protocol. All authors read and approved the final  
2 manuscript.

**STROBE 2007 (v4) checklist of items to be included in reports of observational studies in epidemiology\***  
**Checklist for cohort, case-control, and cross-sectional studies (combined)**

Section/Topic	Item #	Recommendation	Reported on page # in the Document "Manuskript-KIMs-withTC-2017.04.13.docx"
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2-3
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-6
Objectives	3	State specific objectives, including any pre-specified hypotheses	9-10
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	6-8
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6-8, 24-25
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	8-9
		(b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case	Not applicable
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	10-16, see esp. Table 3, p13
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	10-16
Bias	9	Describe any efforts to address potential sources of bias	23-24
Study size	10	Explain how the study size was arrived at	not applicable yet
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	16-24
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	16-24
		(b) Describe any methods used to examine subgroups and interactions	16-24
		(c) Explain how missing data were addressed	19
		(d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	not applicable
		(e) Describe any sensitivity analyses	not applicable yet

For peer review only - <http://bmjopen.bmj.com/site/about/guidelines.xhtml>

Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	not applicable yet
		(b) Give reasons for non-participation at each stage	not applicable yet
		(c) Consider use of a flow diagram	not applicable yet
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	8-9
		(b) Indicate number of participants with missing data for each variable of interest	not applicable yet
		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time	
		<i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure	
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	16-24
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	18-21
		(b) Report category boundaries when continuous variables were categorized	12 (4 categories for considered physical workload, see also Table 3, page 13)
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	19
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	19
<b>Discussion</b>			Planned, not applicable yet
Key results	18	Summarise key results with reference to study objectives	
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	
<b>Other information</b>			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	26

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at [www.strobe-statement.org](http://www.strobe-statement.org).
