## Abstract

**Objectives:** Medical Regulatory Authorities provide licenses to physicians and monitor those physicians once in practice to support their continued competence. In response to physician shortages, many Canadian MRAs developed alternative licensure routes to allow physicians who do not meet traditional licensure criteria to obtain licenses to practice. Many physicians have gained licensure through alternative routes, but the performance of these physicians in practice has not been previously examined. This study compared the performance of traditionally and alternatively licensed physicians in Ontario using quality indicators of primary care. The purpose of this study was to examine the practice performance of alternatively licensed physicians and provide evaluative evidence for alternative licensure policies.

**Design:** A retrospective examination of Ontario health administrative data was conducted using Poisson regression analyses to compare the performance of traditionally and alternatively licensed physicians.

**Setting:** Primary care in Ontario, Canada.

**Participants:** All family physicians who were licensed in Ontario between 2000 and 2012 and who had complete medical billing data in 2014 were included (N=11,419).

**Outcome Measures:** Primary care quality indicators were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates using Ontario health administrative data.

**Results:** Alternatively licensed physicians performed similarly to traditionally licensed physicians in many primary care performance measures. Minimal differences were seen across groups in indicators of diabetic care, congestive heart failure care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years

1  
2  
3 of age, particularly for alternatively licensed physicians who entered Ontario from another  
4  
5 Canadian province.  
6

7  
8 **Conclusions:** Our findings provide initial support for alternative licensure policies and suggest  
9  
10 potential educational content for certain newly licensed physicians. Our study also demonstrates  
11  
12 the utility of administrative data for examining physician performance and evaluating medical  
13  
14 regulatory policies and programs.  
15

### 16 17 18 **Article Summary:**

19  
20  
21 Strengths and limitations of this study:

- 22  
23  
24 • This is the first study to examine the primary care performance of alternatively and  
25  
26 traditionally licensed family physicians in Ontario.
- 27  
28  
29 • Using population-level data across multiple indicators of primary care allowed for a  
30  
31 comprehensive comparison of physicians and using multivariate analysis enabled  
32  
33 statistical adjustment of factors associated with primary care performance.
- 34  
35  
36 • A limitation of this study is that ALPs and TLPs were compared to each other, not to a  
37  
38 gold standard; thus, findings do not indicate whether physicians are meeting performance  
39  
40 benchmarks, only whether ALP performance is comparable to TLP performance.
- 41  
42  
43 • Secondly, results are based on one year of health administrative data which depicts a  
44  
45 point in time and also only represents elements of care that are funded by the Ontario  
46  
47 Ministry of Health and Long-Term care; other important aspects of primary care are not  
48  
49 accounted for.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

- Lastly, quality indicators are proxies for delivery of care; therefore, some of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.

**Key Words:** medical regulation, physician performance, licensure, quality of care, primary care, family medicine

For peer review only

## **The primary care performance of alternatively licensed physicians:**

### **A multivariate regression analysis using administrative data**

A safe and effective healthcare system relies on high quality physician performance. Medical Regulatory Authorities (MRAs) support such performance by issuing licenses to qualified physician applicants and monitoring those physicians once in practice to ensure their continued competence. In the recent past, there has been discussion about the efficacy of regulatory processes for serving professional and public interests (1–3) and calls for evidence-informed regulation through the evaluation of regulatory processes and programs.(3–6) This study heeds such a call by examining the primary care performance of family physicians in Ontario as a way of evaluating regulatory licensure policies and providing information about the care delivered by these physicians.

In Canada, physicians traditionally complete a Canadian residency program and the Canadian qualifying and certification examinations to be granted a license to practice. However, in response to projected physician shortages in the early 2000s, many Canadian MRAs developed alternative licensing criteria to facilitate the licensure of physicians who do not meet the traditional criteria.(7,8) Alternative licensure routes were developed, primarily for International Medical Graduates (IMGs), based on previous experience or licensure, postgraduate training, and/or eligibility to write the Canadian certification exams.(7) Often, these physicians were recruited to work in specific underserved areas and given provisional licenses to practice despite not meeting the traditional qualifications.(9) Smaller Canadian provinces, such as Newfoundland and Saskatchewan, have been prominent issuers of provisional licenses due to their longstanding health human resource needs;(10,11) however, provisionally licensed physicians often move to other parts of the country after completing their service terms, as most

1  
2  
3 are able to practice anywhere in Canada once licensed.(8–12) As such, it is thought that smaller  
4  
5 provinces may serve as entry points to larger provinces such as Ontario.(9,10)  
6  
7

8  
9 In addition to the migration of provisionally licensed physicians across Canada, alternative  
10  
11 licensure routes also allow entry of physicians from the US into Canada and the licensure of  
12  
13 physicians who completed Canadian residency but did not immediately write or pass the national  
14  
15 certification exams. In these cases, provisional licenses are given with the stipulation of  
16  
17 successful exam completion within three years. Although these routes were initially developed to  
18  
19 increase access for IMGs, they are now also utilized by Domestic Medical Graduates (DMGs)  
20  
21 who have not successfully completed exams at the time of licensure.  
22  
23  
24

25  
26 Collectively, Alternatively Licensed Physicians (ALPs) represent physicians who did not meet  
27  
28 the licensure criteria at the time of entering independent practice in a given province but who  
29  
30 were considered to have comparable qualifications to Traditionally Licensed Physicians (TLPs).  
31  
32 The performance of ALPs in practice, however, has not been previously examined. Given that  
33  
34 many ALPs are IMGs, a review of IMG literature may offer insight into ALP practice  
35  
36 performance; however, research comparing IMGs and DMGs has been equivocal. Some studies  
37  
38 show IMGs perform less well than DMGs on certification and licensing examinations,(13–16)  
39  
40 and that such performance is associated with practice performance. (17,18) Yet, IMGs and  
41  
42 DMGs have been shown to be comparable on practice outcomes such as patient mortality,(19,20)  
43  
44 readmission rates,(20) surgical outcomes,(21) and cardiac care.(22)  
45  
46  
47  
48

49  
50 While these conflicting findings may reflect the different outcomes being measured, they may  
51  
52 also stem from the limited definition of IMG being employed. IMGs are typically defined by and  
53  
54 compared on the location of their undergraduate medical training, but this only represents one  
55  
56  
57  
58  
59  
60

1  
2  
3 step in an often long and diverse path of training and experience to independent practice.(7)

4  
5 Examining physicians as defined by later steps in this process, such as point of licensure, may  
6  
7 shed light on why performance differences may or may not exist and how these physicians may  
8  
9 be better supported at different stages of their career.  
10  
11

12  
13 In this study, we compare the performance of alternatively and traditionally licensed family  
14  
15 physicians in Ontario using primary care quality indicators derived from health administrative  
16  
17 data. These indicators were developed and validated by health services researchers to examine  
18  
19 physician performance in areas such as chronic disease management, screening rates, and  
20  
21 hospital readmissions using accepted practice guidelines.(23,24) We focus on the performance of  
22  
23 family physicians licensed through three main alternative routes: those licensed in another  
24  
25 Canadian province, those licensed in the US, and those who trained in Canada but did not  
26  
27 complete certifying examinations at the time of licensure. The research question guiding this  
28  
29 study is: How does the primary care performance of alternatively licensed family physicians  
30  
31 compare to traditionally licensed family physicians in Ontario?  
32  
33  
34  
35  
36  
37

## 38 **METHODS**

### 39 **Study Cohorts**

40  
41  
42 The study population included all practising family physicians in Ontario who were registered  
43  
44 with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and  
45  
46 billed the Ontario Health Insurance Plan (OHIP) in 2014. This population included Traditionally  
47  
48 Licensed Physicians (TLPs) and Alternatively Licensed Physicians (ALPs). TLPs are physicians  
49  
50 who obtained a license to practice by meeting the traditional criteria, namely the completion of  
51  
52 postgraduate training in Canada and successful completion of the national qualifying and  
53  
54  
55  
56  
57  
58  
59  
60

certification examinations (the Medical Council of Canada Qualifying Examinations part 1 and 2, and either the College of Family Physicians of Canada (CFPC) or the Royal College of Physicians and Surgeons of Canada (RCPSC) exams). ALPs are those physicians who were missing one or more of the traditional requirements but met an alternative set of criteria at the time of licensure. There are many alternative licensure routes; in this study, we have focused on the three most commonly used by family physicians, described in Table 1. A more comprehensive description of these routes has been described previously.<sup>(7)</sup>

Table 1. Description of Alternatively Licensed Physician (ALP) subgroups

Out-of-Province ALPs	Physicians who obtained a license in another Canadian province and thus were given an equivalent license in Ontario despite missing one or more traditional licensing requirements <sup>1</sup> or who gained eligibility to write the CFPC examinations by gaining two years of practice experience in another Canadian province and were thus eligible for a provisional license in Ontario <sup>2</sup>
US-Trained ALPs	Physicians who completed postgraduate training in the US but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2,3</sup>
Canadian-Trained ALPs	Physicians who completed postgraduate training in Canada but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2</sup>

<sup>1</sup> *The Agreement on Internal Trade is an interprovincial agreement that was incorporated into Ontario legislation enabling physicians migrating from other Canadian provinces be granted equivalent licenses to practice without assessment or examination*

<sup>2</sup> *Physicians are granted restricted (provisional) licenses and have up to three years to write the Canadian certification examinations*

<sup>3</sup> *Physicians may be granted restricted (provisional) licences due to successful completion of a practice assessment*

## Data Sources

Ontario health administrative datasets held at the Institute for Clinical Evaluative Sciences (ICES) were used in this study. These datasets were linked using unique encoded identifiers and

1  
2  
3 analyzed at ICES under data security and privacy policies and procedures that are approved by  
4 the Office of the Information and Privacy Commissioner of Ontario.(25) The following  
5  
6 administrative databases were used: Canadian Institute for Health Information hospital Discharge  
7  
8 Abstract Database (CIHI-DAD, providing diagnostic information regarding hospital admissions),  
9  
10 OHIP physician claims database (containing physician billings and diagnoses from 1991), the  
11  
12 National Ambulatory Care Reporting System (NACRS) database (providing information on  
13  
14 hospital- and community-based ambulatory care, including emergency department visits, from  
15  
16 2000 and same-day surgery from 1991) , and the Ontario Drug Benefit (ODB) program database  
17  
18 (containing information on all drug therapies dispensed to eligible individuals 65 years of age  
19  
20 and older).  
21  
22  
23  
24  
25

## 26 27 **Variables**

28  
29  
30 Physician demographic characteristics included age, sex, medical school region, and the Human  
31  
32 Development Index (HDI) associated with the physician's country of medical school, which is a  
33  
34 composite score based on life expectancy, education, and per capita income that rank orders all  
35  
36 countries.(26) Physician practice characteristics included practice type (comprehensive or not),  
37  
38 group type (Family Health Team (FHT), non-FHT, no group), scope of practice (percent  
39  
40 providing any of the following: postnatal visits, obstetrical deliveries, postnatal visits, emergency  
41  
42 department (ED) visits, long term care (LTC) visits), and practice location (urban,  
43  
44 suburban/rural). Comprehensive family physicians are those who met specific criteria regarding  
45  
46 the type and scope of services they provide.(27) FHTs are group practices which include  
47  
48 comprehensive family physicians working alongside primary providers such as nurses, social  
49  
50 workers, pharmacists and nutritionists. A detailed description of the physician demographic and  
51  
52 practice characteristics is included in Appendix A.  
53  
54  
55  
56  
57  
58  
59  
60

Primary care quality indicators based on health administrative data were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates. Chronic disease management indicators included measures for diabetes care (HbA1C testing, cholesterol testing, ophthalmology examinations, the receipt of prescriptions for angiotension converting enzyme inhibitors (ACE) and angiotensin II receptor blockers (ARBs)), congestive heart failure (CHF; echocardiogram testing within 12 months of diagnosis, emergency department (ED) visits), asthma (spirometry testing within 12 months of diagnoses, ED visits) and Chronic Obstructive Pulmonary Disease (COPD; spirometry testing within 12 months of diagnoses, ED visits). Pediatric care indicators include well-baby visits, the 18-month enhanced developmental assessment, and the absence of pediatric vaccinations (defined as no billing for any immunization in OHIP). Cancer screening indicators included cervical, breast, and colorectal cancer screening. Hospital readmission rates were calculated at 30 days and one year for patients with a hospital admission. These primary care quality indicators are described in Appendix B.

For each family physician, patients who were either rostered (enrolled) or virtually rostered to them (attributed to the physician based on the majority of their billings) were included. All outcomes denote whether a patient received a given type of care, rather than whether the physician they were rostered to provided it. Therefore, patients who received care from a physician other than their family physician (e.g., a walk-in clinic physician or another family physician in their practice) would appear in the data as having received that care and this would be attributed to the family physician they are rostered to.

## Statistical Analysis

Demographic and practice characteristics are presented as proportions, means, percentage with any, and mean percentages (Table 2). Absolute rates for the primary care quality indicators are presented as means and mean percentages unless otherwise noted (Table 3). Confidence limits (CL) are presented where applicable. To help with interpretation of results, statistically significant differences less than 5% were considered small and statistically significant differences greater than 5% were considered larger.

The relationship between the physician clinical practice characteristics and the outcomes was modelled using Poisson regression with a log offset. Covariates were entered into the model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income and the median age of their patients. The relative rates estimated by the model indicate the difference in outcome between each ALP group and the TLPs (reference group). All analyses were conducted using SAS version 9.3. Ethical approval for this study was received from the Sunnybrook Health Sciences Ethics Review Board.

## RESULTS

### Demographic and Practice Characteristics

A total of 292 ALPs and 11,127 TLPs were included in the study (Table 2). The largest group of ALPs were the Canadian Trained (n=114), followed by the American Trained (n=91) and the Out-of-Province (n=78). The majority of TLPs were men (56.6%) and were older (50.6 years) than all three groups of ALPs. TLPs had fewer IMGs (22.2%) and overwhelmingly came from countries with very high HDI (90.5%). All ALPs were slightly more likely than TLPs to be in

1  
2  
3 comprehensive practice and were less likely to be working in a FHT. Patient age and income  
4  
5 distributions were similar across all groups.  
6  
7

8  
9 The ALP groups' average ages ranged from 42.1 to 50.6 years. The Out-of-Province ALPs had  
10  
11 the highest proportion of men (69%) compared to the other ALP groups. In the Out-of-Province  
12  
13 ALP group, the majority were IMGs (89.7%) and completed medical school in countries  
14  
15 considered medium/low on the HDI (63.2%). Seventy percent (70.1 %) practised in urban  
16  
17 environments and they had the largest proportion in solo practice (32.2%). Similar to Out-of-  
18  
19 Province, the American Trained ALPs were mostly IMGs (85.7%); however, they graduated  
20  
21 primarily from medical schools from countries with a very high/high HDI (68.1%). They had the  
22  
23 largest proportion practising in non-FHT groups (65.9%) and were the most urban group (78%).  
24  
25 Contrary to the other ALPs, almost half (47.4%) of the Canadian Trained ALPs were non-IMGs  
26  
27 and 72.9% came from countries with very high/high HDI. Seventy percent were in  
28  
29 comprehensive practice and they had the lowest percentage in solo practice. They also had the  
30  
31 lowest proportion practising in urban areas compared to all other groups (67.5%).

<i>65+ years</i>	17.7	13.6	15.9	17.1
<i>Patient SES</i>				
<i>% low income</i>	38.0	42.6	42.2	38.9

CL: Confidence Limit | HDI: Human Development Index (2013) | FHT: Family Health Team | ED: Emergency Department | LTC: Long-Term Care

## Primary Care Quality Indicators

Table 3 shows the results of the unadjusted and adjusted comparisons between each ALP group and the TLPs (unadjusted mean numbers are included in Appendix C). Each ALP group had a unique profile of primary care quality indicators. Patients of the Out-of-Province ALPs had the most substantial statistically significant differences in the quality care indicators compared to patients of TLPs after multivariate adjustments. These family physicians' diabetic patients were 4% less likely to have received HbA1C testing and their COPD patients were 18% less likely to have received spirometry testing. Their patients with CHF, COPD or asthma were 7% more likely to visit an ED for any reason (i.e., all-cause) than those of TLPs. Additionally, their female patients aged 50-69 were 4% less likely to have received a mammogram in previous two years and their pediatric patients had 14% fewer well-baby visits, were 24% less likely to have had an 18-month enhanced well-baby visit, and were 38% more likely to have received no immunizations. However, their patients were 4% more likely to receive colon cancer screening and their hospitalized patients were 9% less likely to be readmitted in one year.

In contrast, American Trained ALPs were comparable to their TLP counterparts, with some statistically significant differences. Their diabetic care was similar, although American Trained ALP patients were 8% more likely to have received HbA1c and lipids testing than TLPs' patients. Their pediatric patients were also 27% less likely to have not received any immunizations; however, they were 7% less likely to receive well-baby visits. Canadian Trained ALPs were also similar to their TLP counterparts across most indicators; however, some statistically significant differences were seen: their pediatric patients were 3% less likely to have received well-baby visit but were 34% less likely to have not received any childhood immunizations; their COPD patients were 11% less likely to have had spirometry testing within

## DISCUSSION

Our analysis of primary care quality indicators suggest that alternatively licensed physicians (ALPs) perform similarly to traditionally licensed physicians (TLPs) in many areas of primary care practice. Small differences were seen across groups in indicators of diabetic care, CHF care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age and COPD management, particularly in patients of Out-of-Province ALPs. While individual family physician performance is contextual and influenced by many factors,(28,29) health administrative data is useful for gaining a system-level impression of family physicians' quality of care and identifying areas that are meeting practice benchmarks and areas that may need improvement.(30) Our findings therefore provide support for alternative licensure policies and identify potential educational content for certain newly licensed family physicians.

### Out-of-Province ALPs

Compared to other subgroups, the primary care performance of Out-of-Province ALPs was the most different from TLPs. Most notably, their patients less than two years of age were significantly less likely to receive well baby visits, enhanced 18-month assessments, or immunizations, highlighting a trend in preventive pediatric care. These differences may reflect provincial differences in care expectations for children, as there is significant variation in how 18-month assessments are approached globally and across Canada.(31) Ontario has supported a longer and more comprehensive enhanced 18-month assessment by providing financial incentives through a unique billing code.(31–33) It is possible that Out-of-Province ALPs were unaware of Ontario's enhanced 18-month assessment or of the pediatric care expectations of family

1  
2  
3 physicians in the province. It is also possible that these physicians provided 18-month  
4 assessments but did not bill for it using the Ontario-specific code; however, the trend across all  
5 three preventive pediatric care indicators suggests that the issue may be broader than billing for  
6 this assessment. Previous research has shown that male IMGs who have been in practice for over  
7 10 years are less likely to provide 18-month assessments in Ontario.(34) In this study, age,  
8 gender, and HDI were controlled for, suggesting these factors are not accountable for the  
9 differences; thus, entering Ontario from another province through an alternative route may be an  
10 independent risk factor.  
11

13  
14  
15  
16  
17  
18  
19  
20  
21

22 In addition to differences in preventive pediatric care, Out-of-Province ALPs differed from TLPs  
23 in rates of spirometry testing for COPD patients, which is recommended to confirm a diagnosis  
24 of COPD.(35–38) Previous research has found that spirometry test ordering among family  
25 physicians in Ontario is generally low,(39) and our findings suggest that it is even lower among  
26 Out-of-Province ALPs (and Canadian Trained ALPs) compared to TLPs, highlighting potential  
27 provincial differences in utilization. Out-of-Province ALPs' patients with CHF, COPD, or  
28 asthma also had higher rates of all-cause ED visits, but their hospitalized patients were 9% less  
29 likely to have been readmitted within one year. Rates of all-cause ED visits and readmissions are  
30 sometimes associated with access to primary care,(40–43) but can be influenced by many factors  
31 (43–46) and should thus be interpreted cautiously.  
32

45

46 Overall, our findings highlight the subtle differences in how physicians in different provinces  
47 provide primary care. This has implications for the migration of physicians across provinces  
48 since physicians can typically practice anywhere in Canada once licensed. Given that provisional  
49 licenses have been seen as a way for physicians to gain entry to larger provinces through smaller  
50 ones,(9) the Federation of Medical Regulatory Authorities of Canada has begun to standardize  
51

1  
2  
3 provincial licensure requirements and the Medical Council of Canada is facilitating a common  
4 approach to practice ready assessments for IMGs across the country. While these efforts will  
5 help to mitigate potential performance differences in Canadian physicians, our findings suggest  
6 that ALPs entering Ontario from another province may still benefit from information about  
7 preventive pediatric care at the time of licensure. Focused knowledge translation for family  
8 physicians migrating across provinces may help to educate physicians about province-specific  
9 expectations and support their adoption of provincially-supported programs and guidelines,  
10 reducing the potential for future performance differences.

### 22 **US-Trained and Canadian-Trained ALPs**

23  
24  
25 US-Trained and Canadian-Trained ALPs performed similarly to TLPs on most primary care  
26 quality indicators, though some differences were noted. For both groups, patients less than two  
27 years of age were less likely to receive well baby visits but more likely to receive immunizations.  
28  
29 US-Trained ALPs' diabetic patients were more likely to receive HbA1c and lipid testing and  
30 their patients with CHF, COPD, or asthma were less likely to visit an ED. Canadian-Trained  
31 ALPs' COPD patients were less likely to receive spirometry testing, and their patients with CHF,  
32 COPD, or asthma were more likely to visit an ED. These findings may reflect that US-Trained  
33 ALPs provide better access to primary care than Canadian-Trained ALPs, but further work is  
34 needed to examine factors related to ALP primary care access. Overall, the performance of these  
35 ALPs was comparable to TLPs. This is perhaps unsurprising given that these physicians have  
36 similar postgraduate training. Our findings provide evidence that their practice performance is in  
37 fact similar to traditionally licensed physicians in Ontario.

## Conclusions

Our findings illustrate that ALPs perform similarly to TLPs across many indicators of primary care. These findings provide support for alternative licensure policies and demonstrate the utility of health administrative data for examining physician performance and evaluating regulatory processes. As transparency and accountability are increasingly emphasized in healthcare,(47) and as physician migration and the use of alternative licensure routes continues to increase,(7) it is imperative that processes for licensing and monitoring physicians are rigorously evaluated. The ongoing assessment of physician performance is critical for understanding the effects of medical regulatory policies and, ultimately, for ensuring high quality patient care.

## Strengths and Limitations

This is the first study to examine the primary care performance of alternatively and traditionally licensed family physicians in Ontario. Our use of population-level data across multiple indicators of primary care allowed for a robust and comprehensive comparison of ALPs and TLPs and our use of multivariate analysis enabled statistical adjustment of physician demographics, practice environments, and patient factors, such as SES, that are associated with primary care performance. While this approach contributes to our understanding of ALP performance, it is not without limitations. First, ALPs and TLPs were compared to each other, not to a gold standard. As such, our findings do not indicate whether physicians are meeting performance benchmarks, but rather whether ALP performance is comparable to TLP performance. Second, our results are based on one year of health administrative data which depicts a point in time and also only represents elements of care that are funded by the Ontario Ministry of Health and Long-Term care. Other important aspects of primary care such as the doctor-patient relationship or inter-

1  
2  
3 professional collaboration with other primary health care providers are thus not accounted for.  
4  
5 Last, billing data introduces unique interpretation challenges as these quality indicators are  
6  
7 proxies for delivery of care; therefore, some of the variance in the indicators may be, in part,  
8  
9 attributable to differences in billing practices or factors unrelated to the physician, such as patient  
10  
11 preference.  
12  
13

### 14 15 **Implications for Future Research**

16  
17 This study offers insight into the primary care performance of alternatively licensed physicians.  
18  
19 Primary care is an important area of study given that approximately half of physicians in Ontario  
20  
21 specialize in Family Medicine;(7) however, future research is needed to examine the practice  
22  
23 performance of ALPs practicing in other specialties. Performance is also multi-faceted and must  
24  
25 be studied using a variety of measures. Future studies could include other measures of  
26  
27 performance, such as practice assessments or complaints profiles, to gain a comprehensive  
28  
29 picture of ALPs' practices.  
30  
31  
32  
33

34  
35 This study also demonstrates that licensure route is a useful way of stratifying and comparing  
36  
37 physicians. IMG studies typically define physicians based on their country of undergraduate  
38  
39 medical school, whereas licensure route accounts for the influence of postgraduate training and  
40  
41 previous practice experience on performance. Examining the impact of all of a physician's  
42  
43 training and experience on future practice performance allows for a more robust understanding  
44  
45 of the predictors of performance and may enable more nuanced IMG research in the future.  
46  
47  
48  
49

50  
51 Finally, this study represents a collaboration between a medical regulator and system partners.  
52  
53 Such collaborations are important for linking performance data across the continuum of medical  
54  
55 education and practice (48,49) and for providing evaluative evidence for regulatory processes  
56  
57  
58  
59

1  
2  
3 and policies, such as alternative licensure routes.(4,6) Further collaborations of this nature will  
4  
5 allow for robust examinations of the influence of each stage of a physician's training on future  
6  
7 practice performance.

### Appendix A) Description of Physician Demographic and Practice Characteristic Indicators

Indicator	Description	Definition of indicator
<i>Sex</i>		
<i>Male</i>	Physician sex	Male sex
<i>Female</i>		Female sex
<i>Age</i>	Physician age	Physician age in 2014
<i>HDI Group</i>		
<i>Very high</i>	2013 Human development index associated with the country of undergraduate medical school of physician (26)	HDI rank < 50
<i>High</i>		HDI rank ≥50 and < 103
<i>Medium</i>		HDI rank ≥103 and < 145
<i>Low</i>		HDI rank ≥145
<i>Practice Type</i>		
<i>Comprehensive</i>	Comprehensive practice is if majority of services billed are related to “core primary care” and span multiple practice areas (27)	≥ 44 days worked/yr and > 50% of billing “in core primary care” in at least 7 of 22 practice areas
<i>Other</i>		All other FM physicians
<i>Group type</i>		
<i>FHT</i>	Family Health Team, group practice but not-Family Health Team or solo practice	
<i>non-FHT</i>		
<i>No group</i>

<i>Rurality</i>		
<i>Urban</i>	Practice location categorized in to urban or suburban/rural	RIO < 10
<i>Suburban/Rural</i>	based on 2008 Rurality Index for Ontario (RIO) score (50)	RIO ≥ 10
<i>Scope of practice</i>		
<i>Prenatal visits</i>		% with any billing
<i>Obstetrical Delivery</i>	If the physician submitted billing for care related to: prenatal visits, obstetrical delivery, postnatal visits, Emergency Department, or Long-Term Care	% with any billing
<i>Postnatal visits</i>		% with any billing
<i>ED visits</i>		% with any billing
<i>LTC visits</i>		% with any billing
<i>Patient age distribution</i>		
<i>&lt; 18 years</i>	Pts age categories in 2014	< 18 years
<i>18-64 years</i>		18-64 years
<i>65+ years</i>		65+ years
<i>Patient SES</i>		
<i>% low income</i>	Number of pts in the bottom 40% of neighborhood income	< 3 <sup>rd</sup> quintile of neighborhood income

HDI: Human Development Index | FM: Family Medicine | FHT: Family Health Team |RIO: Rurality Index of Ontario| ED: Emergency Department | LTC: Long-Term Care | Pts: patients | SES: Socio-Economic Status

## Appendix B) Description of Primary Care Quality Indicators

Indicator	Population	Description/guideline	Definition of indicator
<i>Diabetes</i>			
<i>HbA1c</i>		Every 3-6 months, depending on control (51)	2+ HbA1c in previous 12 months
<i>Eye exam</i>		Examination every 1-2 years, depending on severity (51)	Eye exam in previous 24 months
<i>Lipids</i>	Pts with Diabetes Mellitus	Total cholesterol, HDL-C, LDL-C, and TGs annually (51)	1+ cholesterol test in previous 12 months
<i>ACE/ARB</i>		Indicated for pts with high cardiovascular risk (51)	Prescribed ACE/ARB in previous 12 months (pts 65 years of age or older)
<i>Statin</i>		Indicated for pts with elevated lipids (51)	Prescribed statin in previous 12 months (pts 65 years of age or older)
<i>CHF</i>			
<i>Echocardiogram w/in 12 mths of diagnosis</i>	Pts with newly diagnosed CHF	Recommended early after CHF diagnosis for assessment and management (52)	Echocardiogram ordered within 12 months of diagnosis
<i>ED visits/person</i>	Pts with CHF		All cause ED visit in 2014/15
<i>COPD</i>			
<i>Spirometry w/in 12 mths of diagnosis</i>	Pts with newly diagnosed COPD	Recommended for diagnosis (37)	Spirometry within 12 months of diagnosis
<i>ED visits/person</i>	Pts with COPD	All COPD pts, number of ED	All cause ED visit in 2014/15

visits/year			
<i>Asthma</i>			
<i>Spirometry</i>		Recommended to be reassessed regularly and used for diagnosis (53)	Ever had spirometry
<i>ED visits/person</i>	Pts with asthma	All asthma pts number of ED visits/year	All cause ED visit in 2014/15
<i>Preventive Pediatric Care</i>			
<i>Well-baby visits</i>	Pts < 2yrs		Number of visits in first 24 months
<i>18-month enhanced well baby visit</i>	Pts 18 months	Recommended for every child in Ontario (32)	Submitted 18 month billing code
<i>No Immunization</i>	Pts < 2yrs	Publicly funded routine immunizations for children in first 2 yrs (54)	Submitted no billing codes for DTAP, Pneumococcal, MenCC, MMR, Varicella
<i>Cancer Screening</i>			
<i>Mammogram</i>	Female pts 52-69 yrs (excluding breast cancer pts)	Recommended every 2-3 years for pts 50-69 (55)	Mammogram in previous 24 months
<i>Pap test</i>	Female pts 23-69 yrs (excluding cervical and endometrial cancer pts)		Pap in previous 36 months

<i>All colon cancer screening</i>	Pts 52-74 yrs (excluding colon cancer and IBD pts)	FOBT recommended every 1-2 yrs; Colonoscopy every 10 yrs; Flexible Sigmoidoscopy and Double Contrast Barium Enema every 5 years for pts 50- 74	Any FOBT in previous 2 yrs; colonoscopy in previous 10 yrs; other in previous 5 yrs
<hr/>			
<i>Hospital Readmissions</i> <i>Readmission (30 days)</i>	All hospitalized pts	Hospital readmission within 30 days	
<i>Readmission (1 yr)</i>		Hospital readmission within 12 months	
<hr/>			
HbA1c: Haemoglobin A1c (Glycated Haemoglobin)   pts: patients   HDL-C: High-Density Lipoprotein Cholesterol   LDL-C: Low-Density Lipoprotein Cholesterol   TG: Triglycerides   ACE/AARB: Angiotensin Converting Enzyme Inhibitors/ Angiotensin II Receptor Blockers   CHF: Congestive Heart Failure   ED: Emergency Department   COPD: Chronic Obstructive Pulmonary Disease   DTAP: Diphtheria, Tetanus, Pertussis, Polio   MenCC: Meningococcal Conjugate C   MMR: Measles, Mumps, Rubella   PAP: Papanicolaou test   IBD: Inflammatory Bowel Disease   endo: FOBT: Fecal Occult Blood Test

## Declarations

1. Ethics approval: Ethical approval for this study was obtained from the Sunnybrook Health Sciences Center Ethics Review Board
2. Availability of data and material: The datasets included in this study are housed at the Institute for Clinical Evaluative Sciences. A request to the Data Analytic Services (DAS) at ICES is required in order to obtain access to data or analytic services ([www.ices.on.ca/DAS/Data](http://www.ices.on.ca/DAS/Data)).
3. Conflicts of interests: The authors declare that they have no conflicts of interests
4. Funding: The analysis for this study was funded by an annual grant to the Institute for Clinical Evaluative Sciences from the Ontario Ministry of Health and Long-Term Care (MOHLTC)
5. Author contributions: KH, NT, DF, and WY conceptualized this study, interpreted the data, and were key contributors to the manuscript. LJ and SS were responsible for selecting and operationalizing the outcome measures. SS analyzed the data and contributed to writing the manuscript. All authors read and approved the final manuscript.
6. Author information: KH is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Health Services Research from the University of Toronto; NT is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Kinesiology and Health Science from York University; SS is a Senior Epidemiologist at the Institute for Clinical Evaluative Sciences and has an MA in Regional Planning from the University of Waterloo and an MSc in Community Health and Epidemiology from the University of Toronto; LJ is a Senior Scientist at the Institute for Clinical Evaluative Sciences and has an MSc in Community Health and Epidemiology from Queen's University

1  
2  
3 and an MD from McMaster University; DF is the Deputy Registrar at the College of  
4  
5 Physicians and Surgeons of Ontario and has an MBA in Health Services Management from  
6  
7 McMaster University; WY is a Senior Researcher at the College of Physicians and Surgeons  
8  
9 of Ontario and has an MA in Measurement and Evaluation from the University of Toronto  
10  
11 and is currently pursuing a PhD in Adult Education from the University of Toronto.  
12  
13

- 14  
15 7. Acknowledgements: The authors wish to thank Joseph Travers, Karey Iron, Rocco Gerace,  
16  
17 Nathalie Novak, and James Straford of the College of Physicians and Surgeons of Ontario for  
18  
19 their contributions to this project. This study was supported by the Institute for Clinical  
20  
21 Evaluative Sciences (ICES), which is funded by an annual grant from the Ontario Ministry of  
22  
23 Health and Long-Term Care (MOHLTC). The opinions, results and conclusions reported in  
24  
25 this paper are those of the authors and are independent from the funding sources. No  
26  
27 endorsement by ICES or the Ontario MOHLTC is intended or should be inferred. Parts of  
28  
29 this material are based on data and/or information compiled and provided by the Canadian  
30  
31 Institute for Health Information (CIHI), Cancer Care Ontario (CCO) and IMS Brogan.  
32  
33 However, the analyses, conclusions, opinions and statements expressed in the material are  
34  
35 those of the author(s), and not necessarily those of CIHI, CCO or IMS Brogan.

## Abstract

**Objectives:** Medical Regulatory Authorities provide licenses to physicians and monitor those physicians once in practice to support their continued competence. In response to physician shortages, many Canadian MRAs developed alternative licensure routes to allow physicians who do not meet traditional licensure criteria to obtain licenses to practice. Many physicians have gained licensure through alternative routes, but the performance of these physicians in practice has not been previously examined. This study compared the performance of traditionally and alternatively licensed physicians in Ontario using quality indicators of primary care. The purpose of this study was to examine the practice performance of alternatively licensed physicians and provide evaluative evidence for alternative licensure policies.

**Design:** A cross-sectional retrospective examination of Ontario health administrative data was conducted using Poisson regression analyses to compare the performance of traditionally and alternatively licensed physicians.

**Setting:** Primary care in Ontario, Canada.

**Participants:** All family physicians who were licensed in Ontario between 2000 and 2012 and who had complete medical billing data in 2014 were included (N=11,419).

**Outcome Measures:** Primary care quality indicators were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates using Ontario health administrative data.

**Results:** Alternatively licensed physicians performed similarly to traditionally licensed physicians in many primary care performance measures. Minimal differences were seen across groups in indicators of diabetic care, congestive heart failure care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years

1  
2  
3 of age, particularly for alternatively licensed physicians who entered Ontario from another  
4  
5 Canadian province.  
6

7  
8 **Conclusions:** Our findings demonstrate that alternatively licensed physicians perform similarly  
9  
10 to traditionally licensed physicians across many indicators of primary care. Our study also  
11  
12 demonstrates the utility of administrative data for examining physician performance and  
13  
14 evaluating medical regulatory policies and programs.  
15

### 16 17 18 **Article Summary:**

19  
20  
21 Strengths and limitations of this study:

- 22  
23  
24 • This is the first study to examine the primary care performance of alternatively and  
25  
26 traditionally licensed family physicians in Ontario.
- 27  
28  
29 • Using population-level data across multiple indicators of primary care allowed for a  
30  
31 comprehensive comparison of physicians; using multivariate analysis enabled statistical  
32  
33 adjustment of factors associated with primary care performance.
- 34  
35  
36 • A limitation of this study is that ALPs and TLPs were compared to each other, not to a  
37  
38 gold standard; thus, findings do not indicate whether physicians are meeting performance  
39  
40 benchmarks, only whether ALP performance is comparable to TLP performance.
- 41  
42  
43 • Secondly, results are based on one year of health administrative data which depicts a  
44  
45 point in time and also only represents elements of care that are funded by the Ontario  
46  
47 Ministry of Health and Long-Term care; other important aspects of primary care are not  
48  
49 accounted for.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

- Lastly, quality indicators are proxies for delivery of care; therefore, some of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.

**Key Words:** medical regulation, physician performance, licensure, quality of care, primary care, family medicine

For peer review only

**The primary care performance of alternatively licensed physicians in Ontario, Canada:  
A cross-sectional study using administrative data**

A safe and effective healthcare system relies on high quality physician performance. Medical Regulatory Authorities (MRAs) support such performance by issuing licenses to qualified physician applicants and monitoring those physicians once in practice to ensure their continued competence. MRAs also play a role in examining factors that influence physician performance as a way of identifying physician subgroups that may benefit from educational support.(1–8) Additionally, there has been discussion about the efficacy of regulatory processes for serving professional and public interests (9–11) and calls for evidence-informed regulation through the evaluation of regulatory processes and programs.(11–14) This study heeds such a call by examining the primary care performance of family physicians in Ontario as a way of evaluating regulatory licensure policies and exploring the influence of licensure route on physician performance.

In Canada, physicians traditionally complete a Canadian residency program and the Canadian qualifying and certification examinations to be granted a license to practice. However, in response to projected physician shortages in the early 2000s, many Canadian MRAs developed alternative licensing criteria to facilitate the licensure of physicians who do not meet the traditional criteria.(15,16) Alternative licensure routes were developed, primarily for International Medical Graduates (IMGs), based on previous experience or licensure, postgraduate training, and/or eligibility to write the Canadian certification exams.(15) Often, these physicians were recruited to work in specific underserved areas and given provisional licenses to practice despite not meeting the traditional qualifications.(17) Smaller Canadian provinces, such as Newfoundland and Saskatchewan, have been prominent issuers of provisional

1  
2  
3 licenses due to their longstanding health human resource needs;(18,19) however, provisionally  
4 licensed physicians often move to other parts of the country after completing their service terms,  
5  
6 as most are able to practice anywhere in Canada once licensed.(16–20) As such, it is thought that  
7  
8 smaller provinces may serve as entry points to larger provinces such as Ontario.(17,18)  
9

10  
11 In addition to the migration of provisionally licensed physicians across Canada, alternative  
12  
13 licensure routes also allow entry of physicians from the US into Canada and the licensure of  
14  
15 physicians who completed Canadian residency but did not immediately write or pass the national  
16  
17 certification exams. In these cases, provisional licenses are given with the stipulation of  
18  
19 successful exam completion within three years. Although these routes were initially developed to  
20  
21 increase access for IMGs, they are now also utilized by Domestic Medical Graduates (DMGs)  
22  
23 who have not successfully completed exams at the time of licensure.  
24  
25  
26  
27  
28  
29

30  
31 Collectively, Alternatively Licensed Physicians (ALPs) represent physicians who did not meet  
32  
33 the licensure criteria at the time of entering independent practice in a given province but who  
34  
35 were considered to have comparable qualifications to Traditionally Licensed Physicians (TLPs),  
36  
37 based on their postgraduate training and/or professional experience. The performance of ALPs in  
38  
39 practice, however, has not been previously examined. Given that many ALPs are IMGs, a review  
40  
41 of IMG literature may offer insight into ALP practice performance; however, research  
42  
43 comparing IMGs and DMGs has been equivocal. Some studies show IMGs perform less well  
44  
45 than DMGs on certification and licensing examinations,(21–24) and that such performance is  
46  
47 associated with practice performance. (5,25) Yet, IMGs and DMGs have been shown to be  
48  
49 comparable on practice outcomes such as patient mortality,(26,27) readmission rates,(27)  
50  
51 surgical outcomes,(28) and cardiac care.(29)  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 While these conflicting findings may reflect the different outcomes being measured, they may  
4 also stem from the limited definition of IMG being employed. IMGs are typically defined by and  
5 compared on the location of their undergraduate medical training, but this only represents one  
6 step in an often long and diverse path of training and experience to independent practice.(15)  
7  
8 Examining physicians as defined by later steps in this process, such as point of licensure, may  
9 shed light on the impact of postgraduate medical training and early career practice experiences  
10 on subsequent performance and how physicians entering practice through alternative licensure  
11 routes may be better supported at different stages of their career.  
12

17  
18  
19  
20  
21

22 In this study, we sought to understand the impact of alternative licensure routes on the delivery  
23 of primary care in Ontario. We used primary care quality indicators derived from health  
24 administrative data that were developed and validated by health services researchers to examine  
25 physician performance in areas such as chronic disease management, screening rates, and  
26 hospital readmissions using accepted practice guidelines.(30,31) We focused on the performance  
27 of a cohort of family physicians licensed through three main alternative routes: those licensed in  
28 another Canadian province, those licensed in the US, and those who trained in Canada but did  
29 not complete certifying examinations at the time of licensure. The research question guiding this  
30 study was: Does licensure route influence the primary care performance of physicians in  
31 Ontario?

## 47 METHODS

### 48 Approach

1  
2  
3 The objective of this study was to examine the independent contribution of being licensed  
4 through various alternative routes on primary care performance. In order to isolate the effect of  
5 licensure route, we chose to compare each ALP group to TLPs on a variety of quality care  
6 indicators while adjusting for a number of covariates. We do not address the independent impact  
7 of the other variables that were adjusted for, as, practically, we could either focus on a small  
8 number of outcomes and explore the full multivariable models, or examine a broad spectrum of  
9 indicators representative of general family practice and narrow our focus to licensure route. We  
10 chose the latter, as we were interested in primary care performance as a whole rather than  
11 performance on any individual quality indicators. Additionally, the indicators do not have  
12 validated thresholds or gold standard rates at the individual- or population-level, thus  
13 performance is better assessed globally as opposed to focusing on individual tests, screens, or  
14 prescriptions.

### 31 **Study Cohorts**

32  
33  
34 The study population included all practising family physicians in Ontario who were registered  
35 with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and  
36 billed the Ontario Health Insurance Plan (OHIP) in 2014. All publicly-funded health services  
37 provided by physicians are submitted to OHIP. This population included Traditionally Licensed  
38 Physicians (TLPs) and Alternatively Licensed Physicians (ALPs). TLPs are physicians who  
39 obtained a license to practice by meeting the traditional criteria, namely the completion of  
40 postgraduate training in Canada and successful completion of the national qualifying and  
41 certification examinations (the Medical Council of Canada Qualifying Examinations part 1 and  
42 2, and either the College of Family Physicians of Canada (CFPC) or the Royal College of  
43 Physicians and Surgeons of Canada (RCPSC) exams). ALPs are those physicians who were  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

missing one or more of the traditional requirements but met an alternative set of criteria at the time of licensure. There are many alternative licensure routes; in this study, we have focused on the three most commonly used by family physicians, described in Table 1. A more comprehensive description of these routes has been described previously.<sup>(15)</sup>

Table 1. Description of Alternatively Licensed Physician (ALP) subgroups

Out-of-Province ALPs	Physicians who obtained a license in another Canadian province and thus were given an equivalent license in Ontario despite missing one or more traditional licensing requirements <sup>1</sup> or who gained eligibility to write the CFPC examinations by gaining two years of practice experience in another Canadian province and were thus eligible for a provisional license in Ontario <sup>2</sup>
US-Trained ALPs	Physicians who completed postgraduate training in the US but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2,3</sup>
Canadian-Trained ALPs	Physicians who completed postgraduate training in Canada but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2</sup>

<sup>1</sup> *The Agreement on Internal Trade is an interprovincial agreement that was incorporated into Ontario legislation enabling physicians migrating from other Canadian provinces be granted equivalent licenses to practice without assessment or examination*

<sup>2</sup> *Physicians are granted restricted (provisional) licenses and have up to three years to write the Canadian certification examinations*

<sup>3</sup> *Physicians may be granted restricted (provisional) licences due to successful completion of a practice assessment*

## Data Sources

Ontario health administrative datasets held at the Institute for Clinical Evaluative Sciences (ICES) were used in this study. These datasets were linked using unique encoded identifiers and analyzed at ICES under data security and privacy policies and procedures that are approved by the Office of the Information and Privacy Commissioner of Ontario.<sup>(32)</sup> The following administrative databases were used: Canadian Institute for Health Information hospital Discharge

1  
2  
3 Abstract Database (CIHI-DAD, providing diagnostic information regarding hospital admissions),  
4  
5 OHIP physician claims database (containing physician billings and diagnoses from 1991), the  
6  
7 National Ambulatory Care Reporting System (NACRS) database (providing information on  
8  
9 hospital- and community-based ambulatory care, including emergency department visits, from  
10  
11 hospital- and community-based ambulatory care, including emergency department visits, from  
12  
13 2000 and same-day surgery from 1991) , and the Ontario Drug Benefit (ODB) program database  
14  
15 (containing information on all drug therapies dispensed to eligible individuals 65 years of age  
16  
17 and older).

## 18 19 20 **Variables**

21  
22  
23 Physician demographic characteristics included age, sex, medical school region, and the Human  
24  
25 Development Index (HDI) associated with the physician's country of medical school, which is a  
26  
27 composite score based on life expectancy, education, and per capita income that rank orders all  
28  
29 countries.(33) Physician practice characteristics included practice type (comprehensive or not),  
30  
31 group type (Family Health Team (FHT), non-FHT, no group), scope of practice (percent  
32  
33 providing any of the following: postnatal visits, obstetrical deliveries, postnatal visits, emergency  
34  
35 department (ED) visits, long term care (LTC) visits), and practice location (urban,  
36  
37 suburban/rural). Comprehensive family physicians are those who met specific criteria regarding  
38  
39 the type and scope of services they provide.(34) FHTs are group practices which include  
40  
41 comprehensive family physicians working alongside primary providers such as nurses, social  
42  
43 workers, pharmacists and nutritionists. A detailed description of the physician demographic and  
44  
45 practice characteristics is included in Appendix A.  
46  
47  
48  
49

50  
51  
52 Primary care quality indicators based on health administrative data were calculated for chronic  
53  
54 disease management, preventive pediatric care, cancer screening, and hospital readmission rates.  
55  
56  
57  
58  
59

1  
2  
3 Chronic disease management indicators included measures for diabetes care (HbA1C testing,  
4 cholesterol testing, ophthalmology examinations, the receipt of prescriptions for angiotension  
5 converting enzyme inhibitors (ACE) and angiotensin II receptor blockers (ARBs)), congestive  
6 heart failure (CHF; echocardiogram testing within 12 months of diagnosis, emergency  
7 department (ED) visits), asthma (spirometry testing within 12 months of diagnoses, ED visits)  
8 and Chronic Obstructive Pulmonary Disease (COPD; spirometry testing within 12 months of  
9 diagnoses, ED visits). Pediatric care indicators include well-baby visits, the 18-month enhanced  
10 developmental assessment, and the absence of pediatric vaccinations (defined as no billing for  
11 any immunization in OHIP). Cancer screening indicators included cervical, breast, and colorectal  
12 cancer screening. Hospital readmission rates were calculated at 30 days and one year for patients  
13 with a hospital admission. These primary care quality indicators are described in Appendix B.  
14  
15

16  
17 For each family physician, patients who were either rostered (enrolled) or virtually rostered to  
18 them (attributed to the physician based on the majority of their billings) were included. All  
19 outcomes denote whether a patient received a given type of care, rather than whether the  
20 physician they were rostered to provided it. Therefore, patients who received care from a  
21 physician other than their family physician (e.g., a walk-in clinic physician or another family  
22 physician in their practice) would appear in the data as having received that care and this would  
23 be attributed to the family physician they are rostered to.  
24  
25  
26  
27  
28  
29  
30  
31  
32

42  
43  
44  
45

## 46 **Statistical Analysis**

47  
48  
49 Demographic and practice characteristics are presented as proportions, means, percentage with  
50 any, and mean percentages (Table 2). Absolute rates for the primary care quality indicators are  
51 presented as means and mean percentages unless otherwise noted (Table 3). Unadjusted rates are  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 included for comprehensiveness but only the adjusted rates are discussed to answer our research  
4 question. Confidence limits (CL) are presented where applicable. To help with interpretation of  
5 results, statistically significant differences less than 5% were considered small and statistically  
6 significant differences greater than 5% were considered larger.  
7  
8  
9  
10

11  
12  
13 Our multivariate analysis modelled the relationship between physician licensure cohort (ALP  
14 group or TLP) and clinical practice outcomes. Before carrying out the modelling, we tested the  
15 outcome measures for normality and found that many, such as the proportion of a physician's  
16 diabetic patients who received an eye exam within the previous year, were not normally  
17 distributed, but became so after being log transformed. Based on this, we chose to use proc  
18 genmod in SAS to model the number with each characteristic (rather than the proportion) based  
19 on the Poisson distribution and including a log offset. Exponentiating the resulting parameter  
20 estimate gave us the relative rate for each outcome.  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31

32 Each outcome was modeled individually. Covariates were entered into each model in a stepwise  
33 fashion, with only the significant variables retained in the final model. These included grouped  
34 age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was  
35 in a patient enrollment model, HDI group, the proportion of their patients who were low income  
36 and the median age of their patients. The relative rates estimated by the models indicate the  
37 difference in outcome between each ALP group and the TLPs (reference group). All analyses  
38 were conducted using SAS version 9.3. Ethical approval for this study was received from the  
39 Sunnybrook Health Sciences Ethics Review Board.

54  
55 There was no patient or public involvement in this study.  
56  
57  
58  
59  
60

## RESULTS

### Demographic and Practice Characteristics

A total of 292 ALPs and 11,127 TLPs were included in the study (Table 2). The largest group of ALPs were the Canadian Trained (n=114), followed by the US-Trained (n=91) and the Out-of-Province (n=78). The majority of TLPs were men (56.6%) and were older (50.6 years) than all three groups of ALPs. TLPs had fewer IMGs (22.2%) and overwhelmingly came from countries with very high HDI (90.5%). All ALPs were slightly more likely than TLPs to be in comprehensive practice and were less likely to be working in a FHT. Patient age and income distributions were similar across all groups.

The ALP groups' average ages ranged from 42.1 to 50.6 years. The Out-of-Province ALPs had the highest proportion of men (69%) compared to the other ALP groups. In the Out-of-Province ALP group, the majority were IMGs (89.7%) and completed medical school in countries considered medium/low on the HDI (63.2%). Seventy percent (70.1 %) practised in urban environments and they had the largest proportion in solo practice (32.2%). Similar to Out-of-Province, the US-Trained ALPs were mostly IMGs (85.7%); however, they graduated primarily from medical schools from countries with a very high/high HDI (68.1%). They had the largest proportion practising in non-FHT groups (65.9%) and were the most urban group (78%). Contrary to the other ALPs, almost half (47.4%) of the Canadian Trained ALPs were non-IMGs and 72.9% came from countries with very high/high HDI. Seventy percent were in comprehensive practice and they had the lowest percentage in solo practice. They also had the lowest proportion practising in urban areas compared to all other groups (67.5%).

Table 2. Demographic and Practice Characteristics of TLPs and ALPs

Characteristic	All TLPs	Out-of-Province ALPs	US-Trained ALPs	Canadian-Trained ALPs
<i>Total (n)</i>	11127	87	91	114
<i>Sex</i>

## Primary Care Quality Indicators

Table 3 shows the results of the unadjusted and adjusted comparisons between each ALP group and the TLPs (unadjusted mean numbers are included in Appendix C). Each ALP group had a unique profile of primary care quality indicators. Patients of the Out-of-Province ALPs had the most substantial statistically significant differences in the quality care indicators compared to patients of TLPs after multivariate adjustments. These family physicians' diabetic patients were 4% less likely to have received HbA1C testing and their COPD patients were 18% less likely to have received spirometry testing. Their patients with CHF, COPD or asthma were 7% more likely to visit an ED for any reason (i.e., all-cause) than those of TLPs. Additionally, their female patients aged 50-69 were 4% less likely to have received a mammogram in previous two years and their pediatric patients had 14% fewer well-baby visits, were 24% less likely to have had an 18-month enhanced well-baby visit, and were 38% more likely to have received no immunizations. However, their patients were 3% more likely to have received spirometry testing, 4% more likely to receive colon cancer screening, and their hospitalized patients were 9% less likely to be readmitted in one year.

In contrast, US-Trained ALPs were comparable to their TLP counterparts, with some statistically significant differences. Their diabetic care and cancer screening rates were similar, although US-Trained ALP patients were 8% more likely to have received HbA1c and lipids testing than TLPs' patients and 2% more likely to have received a pap test or any colon cancer screening. Their CHF, COPD and asthma patients were also 3% less likely to visit the ED and their pediatric patients were 27% less likely to have not received any immunizations; however, they were 7% less likely to receive well-baby visits. Canadian Trained ALPs were also similar to their TLP counterparts across most indicators; however, some statistically significant differences were

1  
2  
3 seen: their pediatric patients were 3% less likely to have received a well-baby visit but were 34%  
4  
5 less likely to have not received any childhood immunizations; their COPD patients were 11%  
6  
7 less likely to have had spirometry testing within 12 months of diagnosis; and their patients with  
8  
9 CHF, COPD or asthma were 9% more likely to visit an ED (all-cause) than those of TLPs. Minor  
10  
11 differences were seen also seen with HbA1c testing, spirometry testing for asthma patients, and  
12  
13 colon cancer screening, with Canadian-Trained ALP's patients being 3% more likely to have  
14  
15 received testing or screening.

## DISCUSSION

Our analysis of primary care quality indicators suggest that alternatively licensed physicians (ALPs) perform similarly to traditionally licensed physicians (TLPs) in many areas of primary care practice when controlling for a number of covariates. Small differences were seen across groups in indicators of diabetic care, CHF care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age and COPD management, particularly in patients of Out-of-Province ALPs. While individual family physician performance is contextual and influenced by many factors,<sup>(6,35)</sup> health administrative data is useful for gaining a system-level impression of family physicians' quality of care and broadly identifying areas that may need improvement.<sup>(36)</sup> Over all, our findings suggest that alternative licensure route is not a strong independent predictor of family medicine performance on the majority quality indicators examined. For a small number of newly licensed family physicians, educational content pertaining to Ontario-specific guidelines and expectations may be of benefit.

### Out-of-Province ALPs

Compared to other subgroups, the primary care performance of Out-of-Province ALPs was the most different from TLPs after adjustments. Most notably, their patients less than two years of age were significantly less likely to receive well baby visits, enhanced 18-month assessments, or immunizations, highlighting a trend in preventive pediatric care. These differences may reflect provincial differences in guidelines and schedules for pediatric care. For example, there is significant variation in how 18-month assessments are approached globally and across Canada.<sup>(37)</sup> Ontario has supported a longer and more comprehensive enhanced 18-month

1  
2  
3 assessment by providing financial incentives through a unique billing code.(37–39) It is possible  
4 that Out-of-Province ALPs were unaware of Ontario’s enhanced 18-month assessment or of the  
5  
6 pediatric care expectations of family physicians in the province. It is also possible that these  
7  
8 physicians provided 18-month assessments but did not bill for it using the Ontario-specific code.  
9  
10 Previous research has shown that male IMGs who have been in practice for over 10 years are  
11  
12 less likely to provide 18-month assessments in Ontario.(40) In this study, age, gender, and HDI  
13  
14 were controlled for, suggesting these factors are not accountable for the differences; thus,  
15  
16 entering Ontario from another province through an alternative route appears to be an independent  
17  
18 risk factor.  
19  
20  
21  
22  
23

24  
25 Similar to the differences seen in 18-month assessments, the lower childhood immunization rates  
26  
27 in the Out-of-Province ALPs may be in part due to inter-provincial variation in policies. For  
28  
29 example, childhood vaccine schedules differ across provinces (41) which may have implications  
30  
31 for how physicians bill. Further, in Ontario, immunizations for children under two years of age  
32  
33 are predominantly done in physician offices,(42) while they may be administered by nurses or  
34  
35 other allied health professionals in other provinces. Thus, the norms and conventions from their  
36  
37 prior jurisdictions may be reflected in the billing practices of these ALPs once in Ontario.  
38  
39  
40

41  
42 In addition to differences in preventive pediatric care, Out-of-Province ALPs differed from TLPs  
43  
44 in rates of spirometry testing for COPD patients, which is recommended to confirm a diagnosis  
45  
46 of COPD.(43–46) Previous research has found that spirometry test ordering among family  
47  
48 physicians in Ontario is generally low,(47) and our findings suggest that it is even lower among  
49  
50 Out-of-Province ALPs (and Canadian Trained ALPs) compared to TLPs, highlighting potential  
51  
52 provincial differences in utilization. Out-of-Province ALPs’ patients with CHF, COPD, or  
53  
54 asthma also had higher rates of all-cause ED visits, but their hospitalized patients were 9% less  
55  
56  
57  
58  
59

likely to have been readmitted within one year. Rates of all-cause ED visits and readmissions are sometimes associated with access to primary care,(48–51) but can be influenced by many factors (51–54) and should thus be interpreted cautiously.

Overall, our findings highlight that ALPs entering Ontario from another Canadian province perform differently than TLPs in certain indicators of primary care. However, the performance differences noted in this study may be due to provincial differences in care expectations and reflect the context of their recent work environments. Such provincial differences in how physicians provide primary care have implications for the migration of physicians across provinces since physicians can typically practice anywhere in Canada once licensed. Given that provisional licenses have been seen as a way for physicians to gain entry to larger provinces through smaller ones,(17) the Federation of Medical Regulatory Authorities of Canada has begun to standardize provincial licensure requirements and the Medical Council of Canada is facilitating a common approach to practice ready assessments for IMGs across the country. While these efforts will help to mitigate potential performance differences in Canadian physicians, our findings suggest that ALPs entering Ontario from another province may still benefit from information about Ontario care expectations at the time of licensure. Focused knowledge translation for family physicians migrating across provinces may help to educate physicians about province-specific expectations and support their adoption of provincially-supported programs and guidelines, reducing the potential for future performance differences.

### **US-Trained and Canadian-Trained ALPs**

US-Trained and Canadian-Trained ALPs performed similarly to TLPs on most primary care quality indicators after adjustments, though some notable differences were seen. For both groups,

1  
2  
3 patients less than two years of age were less likely to receive well baby visits but more likely to  
4 receive immunizations. In contrast to the Out-of province ALPs, whose patients were more likely  
5 to have not received any early childhood immunizations, US- and Canadian-Trained ALP  
6 patients were much more likely to receive them compared to the rest of the province: this 27-  
7 34% difference was the largest difference seen between these groups and the TLPs. US-Trained  
8 ALPs' patients were also more likely to receive pap tests and colon cancer screenings, their  
9 diabetic patients were more likely to receive HbA1c and lipid testing, and their patients with  
10 CHF, COPD, or asthma were less likely to visit an ED. The higher rates of testing and screening  
11 may be reflective of their American training, as previous research has found American  
12 physicians tend to have lower thresholds for diagnostic and therapeutic interventions.(55) Similar  
13 to Out-of-Province ALPs, Canadian-Trained ALPs' COPD patients were less likely to receive  
14 spirometry testing, and their patients with CHF, COPD, or asthma were more likely to visit an  
15 ED. Overall, the performance of both of these ALP groups was comparable to TLPs. This is  
16 perhaps unsurprising given that these physicians have similar postgraduate training, and that  
17 postgraduate training has been found to be predictive of patient outcomes.(56) Our findings  
18 provide evidence that their practice performance is in fact similar to traditionally licensed  
19 physicians in Ontario.

## 42 **Conclusions**

43  
44  
45  
46 Our findings illustrate that ALPs perform similarly to TLPs across many indicators of primary  
47 care, suggesting that route of licensure is not a strong predictor of family physician performance  
48 in Ontario. These findings provide support for alternative licensure policies and also demonstrate  
49 the utility of health administrative data for examining physician performance and evaluating  
50 regulatory processes. As transparency and accountability are increasingly emphasized in

healthcare,(57) and as physician migration and the use of alternative licensure routes continues to increase,(15) it is imperative that processes for licensing and monitoring physicians are rigorously evaluated. The ongoing assessment of physician performance is critical for understanding the effects of medical regulatory policies and, ultimately, for ensuring high quality patient care.

### **Strengths and Limitations**

This is the first study to examine the primary care performance of alternatively and traditionally licensed family physicians in Ontario. Our use of population-level data across multiple indicators of primary care allowed for a robust and comprehensive comparison of ALPs and TLPs and our use of multivariate analysis enabled statistical adjustment of physician demographics, practice environments, and patient factors, such as SES, that are associated with primary care performance. While this approach contributes to our understanding of ALP performance, it is not without limitations. First, ALPs and TLPs were compared to each other, not to a gold standard. As such, our findings do not indicate whether physicians are meeting performance benchmarks, but rather whether ALP performance is comparable to TLP performance. Second, our results are based on one year of health administrative data which depicts a point in time and also only represents elements of care that are funded by the Ontario Ministry of Health and Long-Term care. Other important aspects of primary care such as the doctor-patient relationship or inter-professional collaboration with other primary health care providers are thus not accounted for. Last, billing data introduces unique interpretation challenges as these quality indicators are proxies for delivery of care; therefore, some of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.

### Implications for Future Research

This study offers insight into the primary care performance of alternatively licensed physicians. Primary care is an important area of study given that approximately half of physicians in Ontario specialize in Family Medicine;(15) however, future research is needed to examine the practice performance of ALPs practicing in other specialties. Performance is also multi-faceted and must be studied using a variety of measures. Future studies could include other measures of performance, such as practice assessments or complaints profiles, to gain a comprehensive picture of ALPs' practices.

This study also demonstrates that licensure route is a useful way of stratifying and comparing physicians. IMG studies typically define physicians based on their country of undergraduate medical school, whereas licensure route accounts for the influence of postgraduate training and previous practice experience on performance. Examining the impact of all of a physician's training and experience on future practice performance allows for a more robust understanding of the predictors of performance and may enable more nuanced IMG research in the future.

Finally, this study represents a collaboration between a medical regulator and system partners. Such collaborations are important for linking performance data across the continuum of medical education and practice (58,59) and for providing evaluative evidence for regulatory processes and policies, such as alternative licensure routes.(12,14) Further collaborations of this nature will allow for robust examinations of the influence of each stage of a physician's training on future practice performance.

## Declarations

1. Ethics approval: Ethical approval for this study was obtained from the Sunnybrook Health Sciences Center Ethics Review Board
2. Availability of data and material: The datasets included in this study are housed at the Institute for Clinical Evaluative Sciences. A request to the Data Analytic Services (DAS) at ICES is required in order to obtain access to data or analytic services ([www.ices.on.ca/DAS/Data](http://www.ices.on.ca/DAS/Data)).
3. Conflicts of interests: The authors declare that they have no conflicts of interests
4. Funding: The analysis for this study was funded by an annual grant to the Institute for Clinical Evaluative Sciences from the Ontario Ministry of Health and Long-Term Care (MOHLTC)
5. Author contributions: KH, NT, DF, and WY conceptualized this study, interpreted the data, and were key contributors to the manuscript. LJ and SS were responsible for selecting and operationalizing the outcome measures. SS analyzed the data and contributed to writing the manuscript. All authors read and approved the final manuscript.
6. Author information: KH is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Health Services Research from the University of Toronto; NT is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Kinesiology and Health Science from York University; SS is a Senior Epidemiologist at the Institute for Clinical Evaluative Sciences and has an MA in Regional Planning from the University of Waterloo and an MSc in Community Health and Epidemiology from the University of Toronto; LJ is a Senior Scientist at the Institute for Clinical Evaluative Sciences and has an MSc in Community Health and Epidemiology from Queen's University

1  
2  
3 and an MD from McMaster University; DF is the Deputy Registrar at the College of  
4  
5 Physicians and Surgeons of Ontario and has an MBA in Health Services Management from  
6  
7 McMaster University; WY is a Senior Researcher at the College of Physicians and Surgeons  
8  
9 of Ontario and has an MA in Measurement and Evaluation from the University of Toronto  
10  
11 and is currently pursuing a PhD in Adult Education from the University of Toronto.

**Appendix A) Description of Physician Demographic and Practice Characteristic Indicators**

<b>Indicator</b>	<b>Description</b>	<b>Definition of indicator</b>
<i>Sex</i>		
<i>Male</i>	Physician sex	Male sex
<i>Female</i>		Female sex
<i>Age</i>	Physician age	Physician age in 2014
<i>HDI Group</i>	2013 Human development index associated with the country of undergraduate medical school of physician (26)	
<i>Very high</i>		HDI rank < 50
<i>High</i>		HDI rank ≥50 and < 103
<i>Medium</i>		HDI rank ≥103 and < 145
<i>Low</i>	HDI rank ≥145	
<i>Practice Type</i>		
<i>Comprehensive</i>	Comprehensive practice is if majority of services billed are related to “core primary care” and span multiple practice areas (27)	≥ 44 days worked/yr and > 50% of billing “in core primary care” in at least 7 of 22 practice areas
<i>Other</i>		All other FM physicians
<i>Group type</i>		
<i>FHT</i>	Family Health Team, group practice but not-Family Health Team or solo practice	
<i>non-FHT</i>		
<i>No group</i>		
<i>Rurality</i>		
<i>Urban</i>	Practice location categorized in to urban or suburban/rural based on 2008 Rurality Index for Ontario (RIO) score (50)	RIO < 10
<i>Suburban/Rural</i>		RIO ≥ 10
<i>Scope of practice</i>		
<i>Prenatal visits</i>	If the physician submitted billing for care related to: prenatal	% with any billing

<i>Obstetrical Delivery</i>	visits, obstetrical delivery, postnatal visits, Emergency	% with any billing
<i>Postnatal visits</i>	Department, or Long-Term Care	% with any billing
<i>ED visits</i>		% with any billing
<i>LTC visits</i>		% with any billing
<hr/>		
<i>Patient age distribution</i>		
<i>&lt; 18 years</i>		< 18 years
<i>18-64 years</i>	Pts age categories in 2014	18-64 years
<i>65+ years</i>		65+ years
<hr/>		
<i>Patient SES</i>		
<i>% low income</i>	Number of pts in the bottom 40% of neighborhood income	< 3 <sup>rd</sup> quintile of neighborhood income

HDI: Human Development Index | FM: Family Medicine | FHT: Family Health Team | RIO: Rurality Index of Ontario | ED: Emergency Department | LTC: Long-Term Care | Pts: patients | SES: Socio-Economic Status

## Appendix B) Description of Primary Care Quality Indicators

Indicator	Population	Description/guideline	Definition of indicator
<i>Diabetes</i>			
<i>HbA1c</i>		Every 3-6 months, depending on control (51)	2+ HbA1c in previous 12 months
<i>Eye exam</i>		Examination every 1-2 years, depending on severity (51)	Eye exam in previous 24 months
<i>Lipids</i>	Pts with Diabetes Mellitus	Total cholesterol, HDL-C, LDL-C, and TGs annually (51)	1+ cholesterol test in previous 12 months
<i>ACE/ARB</i>		Indicated for pts with high cardiovascular risk (51)	Prescribed ACE/ARB in previous 12 months (pts ≥65 years of age or older)
<i>Statin</i>		Indicated for pts with elevated lipids (51)	Prescribed statin in previous 12 months (pts ≥65 years of age or older)
<i>CHF</i>			
<i>Echocardiogram w/in 12 mths of diagnosis</i>	Pts with newly diagnosed CHF	Recommended early after CHF diagnosis for assessment and management (52)	Echocardiogram ordered within 12 months of diagnosis
<i>ED visits/person</i>	Pts with CHF		All cause ED visit in 2014/15
<i>COPD</i>			
<i>Spirometry w/in 12 mths of diagnosis</i>	Pts with newly diagnosed COPD	Recommended for diagnosis (37)	Spirometry within 12 months of diagnosis
<i>ED visits/person</i>	Pts with COPD	All COPD pts, number of ED visits/year	All cause ED visit in 2014/15

<i>Asthma</i>			
<i>Spirometry</i>		Recommended to be reassessed regularly and used for diagnosis (53)	Ever had spirometry
<i>ED visits/person</i>	Pts with asthma	All asthma pts number of ED visits/year	All cause ED visit in 2014/15
<i>Preventive Pediatric Care</i>			
<i>Well-baby visits</i>	Pts < 2yrs		Number of visits in first 24 months
<i>18-month enhanced well baby visit</i>	Pts 18 months	Recommended for every child in Ontario (32)	Submitted 18 month billing code
<i>No Immunization</i>	Pts < 2yrs	Publicly funded routine immunizations for children in first 2 yrs (54)	Submitted no billing codes for DTAP, Pneumococcal, MenCC, MMR, Varicella
<i>Cancer Screening</i>			
<i>Mammogram</i>	Female pts 52-69 yrs (excluding breast cancer pts)	Recommended every 2-3 years for pts 50-69 (55)	Mammogram in previous 24 months
<i>Pap test</i>	Female pts 23-69 yrs (excluding cervical and endometrial cancer pts)		Pap in previous 36 months
<i>All colon cancer screening</i>	Pts 52-74 yrs (excluding colon cancer and IBD pts)	FOBT recommended every 1-2 yrs; Colonoscopy every 10 yrs; Flexible Sigmoidoscopy and Double Contrast Barium Enema every 5years for pts 50-74	Any FOBT in previous 2 yrs; colonoscopy in previous 10 yrs; other in previous 5 yrs

STROBE Statement—checklist of items that should be included in reports of observational studies  
NOTE: Page Numbers refer to “clean” (i.e. unmarked) version of manuscript

	Item No.	Recommendation	Page No.	Relevant text from manuscript
<b>Title and abstract</b>	1	(a) Indicate the study’s design with a commonly used term in the title or the abstract	1	The primary care performance of alternatively licensed physicians in Ontario, Canada: A cross-sectional study using administrative data
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	3-4	A cross-sectional retrospective examination of Ontario health administrative data was conducted using Poisson regression analyses to compare the performance of traditionally and alternatively licensed physicians. Minimal differences were seen across groups in indicators of diabetic care, congestive heart failure care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age, particularly for alternatively licensed physicians who entered Ontario from another Canadian province.
<b>Introduction</b>				
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	7-8	Collectively, Alternatively Licensed Physicians (ALPs) represent physicians who did not meet the licensure criteria at the time of entering independent practice in a given province but who were considered to have comparable qualifications to Traditionally Licensed Physicians (TLPs), based on their postgraduate training and/or professional experience. The performance of ALPs in practice, however, has not been previously examined. Given that many ALPs are IMGs, a review of IMG literature may offer insight into ALP practice performance; however, research comparing IMGs and DMGs has been equivocal. IMGs are typically defined by and compared on the location of their undergraduate medical training, but this only represents one step in an often long and diverse path of training and experience to independent practice. Examining physicians as defined by later steps in this process, such as point of licensure, may shed light on the impact of postgraduate medical training and early career practice experiences on subsequent performance and how physicians entering practice through alternative licensure routes may be better supported at different

				stages of their career
Objectives	3	State specific objectives, including any prespecified hypotheses	8	The research question guiding this study was: Does licensure route influence the primary care performance of physicians in Ontario?
<b>Methods</b>				
Study design	4	Present key elements of study design early in the paper	9	In order to isolate the effect of licensure route, we chose to compare each ALP group to TLPs while adjusting for a number of covariates. We do not address the independent impact of the other variables that were adjusted for, as we felt we could either focus on a small number of outcomes and explore the full multivariable models, or examine a broad spectrum of indicators representative of general family practice and narrow our focus to licensure route. We chose the latter, as we were interested in primary care performance as a whole rather than performance on any individual quality indicators.
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
Participants	6	<i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
		<i>(b) Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case		NA
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	11-12 and supplementary file	Physician demographic characteristics included age, sex, medical school region, and the Human Development Index (HDI) associated with the physician’s country of medical school, which is a composite score based on life expectancy, education, and per capita income that rank orders all countries. <sup>(13)</sup> Physician practice characteristics included practice type (comprehensive or not), group type (Family Health Team (FHT), non-FHT, no group), scope of practice (percent providing any of the following: postnatal visits, obstetrical deliveries, postnatal visits, emergency department (ED) visits, long term care (LTC) visits), and practice location (urban, suburban/rural). Comprehensive family physicians are

bmjopen-2019-026266

those who met specific criteria regarding the type and scope of services they provide.(34) FHTs are group practices which include comprehensive family physicians working alongside primary providers such as nurses, social workers, pharmacists and nutritionists. A detailed description of the physician demographic and practice characteristics is included in Appendix A.

Primary care quality indicators based on health administrative data were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates. Chronic disease management indicators included measures for diabetes care (HbA1C testing, cholesterol testing, ophthalmology examinations, the receipt of prescriptions for angiotension converting enzyme inhibitors (ACE) and angiotensin II receptor blockers (ARBs)), congestive heart failure (CHF; echocardiogram testing within 12 months of diagnosis, emergency department (ED) visits), asthma (spirometry testing within 12 months of diagnoses, ED visits) and Chronic Obstructive Pulmonary Disease (COPD; spirometry testing within 12 months of diagnoses, ED visits). Pediatric care indicators include well-baby visits, the 18-month enhanced developmental assessment, and the absence of pediatric vaccinations (defined as no billing for any immunization in OHIP). Cancer screening indicators included cervical, breast, and colorectal cancer screening. Hospital readmission rates were calculated at 30 days and one year for patients with a hospital admission. These primary care quality indicators are described in Appendix B.

Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	10-11
---------------------------	----	--	-------

Ontario health administrative datasets held at the Institute for Clinical Evaluative Sciences (ICES) were used in this study. These datasets were linked using unique encoded identifiers and analyzed at ICES under data security and privacy policies and procedures that are approved by the Office of the Information and Privacy Commissioner of Ontario.(32) The following administrative databases were used: Canadian Institute for Health Information hospital Discharge Abstract Database (CIHI-DAD, providing diagnostic information regarding hospital admissions), OHIP physician claims database (containing physician billings and diagnoses from 1991), the National Ambulatory Care Reporting System (NACRS) database (providing information on hospital- and

				community-based ambulatory care, including emergency department visits, from 2000 and same-day surgery from 1991), and the Ontario Drug Benefit (ODB) program database (containing information on all drug therapies dispensed to eligible individuals 65 years of age and older)
Bias	9	Describe any efforts to address potential sources of bias	13	Covariates were entered into the model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income and the median age of their patients.
Study size	10	Explain how the study size was arrived at	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	11-12 and supplementary file	See item 7
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	13	Our multivariate analysis modelled the relationship between physician licensure cohort (ALP group or TLP) and clinical practice outcomes. Before carrying out the modelling, we tested the outcome measures for normality and found that many, such as the proportion of a physician's diabetic patients who received an eye exam within the previous year, were not normally distributed, but became so after being log transformed. Based on this, we chose to use proc genmod in SAS to model the number with each characteristic (rather than the proportion) based on the Poisson distribution and including a log offset. Exponentiating the resulting parameter estimate gave us the relative rate for each outcome. Each outcome was modelled individually. Covariates were entered into the model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income and the median age of their patients. The relative rates estimated by the model indicate the difference in outcome between each ALP group and the TLPs (reference group).
		(b) Describe any methods used to examine		NA

		subgroups and interactions		
		(c) Explain how missing data were addressed	9	The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 <b>and billed the Ontario Health Insurance Plan (OHIP) in 2014. All publicly funded health services provided by physicians are submitted to OHIP.</b>
		(d) <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy		NA
		(e) Describe any sensitivity analyses		NA
<b>Results</b>				
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	14 9	A total of 792 ALPs and 11,127 TLPs were included in the study  The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014
		(b) Give reasons for non-participation at each stage		NA
		(c) Consider use of a flow diagram		NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	14-16	A total of 792 ALPs and 11,127 TLPs were included in the study (Table 2). The largest group of ALPs were the Canadian Trained (n=114), followed by the US-Trained (n=91) and the Out-of-Province (n=78). The majority of TLPs were men (56.6%) and were older (50.6 years) than all three groups of ALPs. TLPs had fewer IMGs (22.4%) and overwhelmingly came from countries with very high HDI (90.5%). All ALPs were slightly more likely than TLPs to be in comprehensive practice and were less likely to be working in a FHT. Patient age and income distributions were similar across all groups. The ALP groups' average ages ranged from 42.1 to 50.6 years. The Out-of-Province ALPs had the highest proportion of men (69%) compared to the other ALP groups. In the Out-of-Province ALP group, the majority were IMGs (89.7%) and completed medical school in countries considered medium/low on the HDI (63.2%). Seventy percent (70.1 %) practised in urban environments and they

				had the largest proportion in solo practice (32.2%). Similar to Out-of-Province, the US-Trained ALPs were mostly IMGs (85.7%); however, they graduated primarily from medical schools from countries with a very high/high HDI (68.1%). They had the largest proportion practising in non-FHT groups (65.9%) and were the most urban group (78%). Contrary to the other ALPs, almost half (47.4%) of the Canadian Trained ALPs were non-IMGs and 72.9% came from countries with very high/high HDI. Seventy percent were in comprehensive practice and they had the lowest percentage in solo practice. They also had the lowest proportion practising in urban areas compared to all other groups (67.5%).
		(b) Indicate number of participants with missing data for each variable of interest	9	The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 <b>and billed the Ontario Health Insurance Plan (OHIP) in 2014. All publicly funded health services provided by physicians are submitted to OHIP.</b>
		(c) Cohort study—Summarise follow-up time (eg, average and total amount)		NA
Outcome data	15*	Cohort study—Report numbers of outcome events or summary measures over time		NA
		Case-control study—Report numbers in each exposure category, or summary measures of exposure		NA

		time period		
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses		NA
<b>Discussion</b>				
Key results	18	Summarise key results with reference to study objectives	21	Our analysis of primary care quality indicators suggest that alternatively licensed physicians (ALPs) perform similarly to traditionally licensed physicians (TLPs) in many areas of primary care practice when controlling for a number of covariates. Small differences were seen across groups in indicators of diabetic care, CHF care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age and COPD management, particularly in patients of Out-of-Province ALPs. While individual family physician performance is contextual and influenced by many factors,(6,35) health administrative data is useful for gaining a system-level impression of family physicians' quality of care and identifying areas that are meeting practice benchmarks and areas that may need improvement.(36) Over all, our findings suggest that alternative licensure route is not a strong independent predictor of family medicine performance on the majority quality indicators examined. For a small number of newly licensed family physicians, educational content pertaining to Ontario-specific guidelines and expectations may be of benefit.
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	26-27	First, ALPs and TLPs were compared to each other, not to a gold standard. As such, our findings do not indicate whether physicians are meeting performance benchmarks, but rather whether ALP performance is comparable to TLP performance. Second, our results are based on one year of health administrative data which depicts a point in time and also only represents elements of care that are funded by the Ontario Ministry of Health and Long-Term care. Other important aspects of primary care such as the doctor-patient relationship or inter-professional collaboration with other primary health care providers are thus not accounted for. Last, billing data introduces unique interpretation challenges as these quality indicators are proxies for delivery of care; therefore, some

Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	21-24	<p>of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.</p> <p>Compared to other subgroups, the primary care performance of Out-of-Province ALPs was the most different from TLPs after adjustments. Most notably, their patients less than two years of age were significantly less likely to receive well baby visits, enhanced 18-month assessments, or immunizations, highlighting a trend in preventive pediatric care. These differences may reflect provincial differences in guidelines and schedules for pediatric care. For example, there is significant variation in how 18-month assessments are approached globally and across Canada. Ontario has supported a longer and more comprehensive enhanced 18-month assessment by providing financial incentives through a unique billing code. It is possible that Out-of-Province ALPs were unaware of Ontario's enhanced 18-month assessment or of the pediatric care expectations of family physicians in the province. It is also possible that these physicians provided 18-month assessments but did not bill for it using the Ontario-specific code. Previous research has shown that male IMGs who have been in practice for over 10 years are less likely to provide 18-month assessments in Ontario (40). In this study, age, gender, and HDI were controlled for, suggesting these factors are not accountable for the differences; thus, entering Ontario from another province through an alternative route appears to be an independent risk factor.</p> <p>Similar to the differences seen in 18-month assessments, the lower childhood immunization rates in the Out-of-Province ALPs may be in part due to inter-provincial variation in policies. For example, childhood vaccine schedules differ across provinces which may have implications for how physicians bill. Further, in Ontario, immunizations for children under two years of age are predominantly done in physician offices, while they may be administered by nurses or other allied health professionals in other provinces. Thus, the norms and conventions from their prior jurisdictions may be reflected in the billing practices of these ALPs once in</p>
----------------	----	--	-------	--

For peer review only

Ontario. In addition to differences in preventive pediatric care, Out-of-Province ALPs differed from TLPs in rates of spirometry testing for COPD patients, which is recommended to confirm a diagnosis of COPD. Previous research has found that spirometry test ordering among family physicians in Ontario is generally low, and our findings suggest that it is even lower among Out-of-Province ALPs (and Canadian Trained ALPs) compared to TLPs, highlighting potential provincial differences in utilization. Out-of-Province ALPs' patients with CHF, COPD, or asthma also had higher rates of all-cause ED visits, but their hospitalized patients were 9% less likely to have been readmitted within one year. Rates of all-cause ED visits and readmissions are sometimes associated with access to primary care, but can be influenced by many factors and should thus be interpreted cautiously.

Overall, our findings highlight that ALPs entering Ontario from another Canadian province perform differently than TLPs in certain indicators of primary care. However, the performance differences noted in this study may be due to provincial differences in care expectations and reflect the context of their recent work environments. Such provincial differences in how physicians provide primary care have implications for the migration of physicians across provinces since physicians can typically practice anywhere in Canada once licensed. Given that provisional licenses have been seen as a way for physicians to gain entry to larger provinces through smaller ones, the Federation of Medical Regulatory Authorities of Canada has begun to standardize provincial licensure requirements and the Medical Council of Canada is facilitating a common approach to practice ready assessments for IMGs across the country. While these efforts will help to mitigate potential performance differences in Canadian physicians, our findings suggest that ALPs entering Ontario from another province may still benefit from information about Ontario care expectations at the time of licensure. Focused knowledge translation for family physicians migrating across

provinces may help to educate physicians about province-specific expectations and support their adoption of provincially-supported programs and guidelines, reducing the potential for future performance differences. US-Trained and Canadian-Trained ALPs performed similarly to TLPs on most primary care quality indicators after adjustments, though some notable differences were seen. For both groups, patients less than two years of age were less likely to receive well baby visits but more likely to receive immunizations. In contrast to the Out-of-province ALPs, whose patients were more likely to have not received any early childhood immunizations, US- and Canadian-trained ALP patients were much more likely to receive them compared to the rest of the province: this 27-34% difference was the largest difference seen between these groups and the TLPs. US-Trained ALPs' patients were also more likely to receive pap tests and colon cancer screenings, their diabetic patients were more likely to receive HbA1c and lipid testing, and their patients with CHF, COPD, or asthma were less likely to visit an ED. The higher rates of testing and screening may be reflective of their American training, as previous research has found American physicians tend to have lower thresholds for diagnostic and therapeutic interventions. Similar to Out-of-Province ALPs, Canadian-Trained ALPs' COPD patients were less likely to receive spirometry testing, and their patients with CHF, COPD, or asthma were more likely to visit an ED. Overall, the performance of both of these ALP groups was comparable to TLPs. This is perhaps unsurprising given that these physicians have similar postgraduate training, and that postgraduate training has been found to be predictive of patient outcomes. Our findings provide evidence that their practice performance is in fact similar to traditionally licensed physicians in Ontario.

Generalisability	21	Discuss the generalisability (external validity) of the study results	26	This study offers insight into the primary care performance of alternatively licensed physicians. Primary care is an important area of study given that approximately half of physicians in Ontario specialize in Family Medicine;(15) however, future research is needed to examine the practice performance of ALPs practicing in other specialties. Performance is also multi-faceted and must be studied using a variety of measures. Future studies could include other measures of performance, such as practice assessments or complaints profiles, to gain a comprehensive picture of ALPs' practices.

## Abstract

**Objectives:** Medical Regulatory Authorities provide licenses to physicians and monitor those physicians once in practice to support their continued competence. In response to physician shortages, many Canadian MRAs developed alternative licensure routes to allow physicians who do not meet traditional licensure criteria to obtain licenses to practice. Many physicians have gained licensure through alternative routes, but the performance of these physicians in practice has not been previously examined. This study compared the performance of traditionally and alternatively licensed physicians in Ontario using quality indicators of primary care. The purpose of this study was to examine the practice performance of alternatively licensed physicians and provide evaluative evidence for alternative licensure policies.

**Design:** A cross-sectional retrospective examination of Ontario health administrative data was conducted using Poisson regression analyses to compare the performance of traditionally and alternatively licensed physicians.

**Setting:** Primary care in Ontario, Canada.

**Participants:** All family physicians who were licensed in Ontario between 2000 and 2012 and who had complete medical billing data in 2014 were included (N=11,419).

**Outcome Measures:** Primary care quality indicators were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates using Ontario health administrative data.

**Results:** Alternatively licensed physicians performed similarly to traditionally licensed physicians in many primary care performance measures. Minimal differences were seen across groups in indicators of diabetic care, congestive heart failure care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years

1  
2  
3 of age, particularly for alternatively licensed physicians who entered Ontario from another  
4  
5 Canadian province.  
6

7  
8 **Conclusions:** Our findings demonstrate that alternatively licensed physicians perform similarly  
9  
10 to traditionally licensed physicians across many indicators of primary care. Our study also  
11  
12 demonstrates the utility of administrative data for examining physician performance and  
13  
14 evaluating medical regulatory policies and programs.  
15

### 16 17 18 **Article Summary:**

19  
20  
21 Strengths and limitations of this study:

- 22  
23  
24 • This is the first study to examine the primary care performance of alternatively and  
25  
26 traditionally licensed family physicians in Ontario.  
27
- 28  
29 • Using population-level data across multiple indicators of primary care allowed for a  
30  
31 comprehensive comparison of physicians; using multivariable analysis enabled statistical  
32  
33 adjustment of factors associated with primary care performance.  
34
- 35  
36 • A limitation of this study is that ALPs and TLPs were compared to each other, not to a  
37  
38 gold standard; thus, findings do not indicate whether physicians are meeting performance  
39  
40 benchmarks, only whether ALP performance is comparable to TLP performance.  
41
- 42  
43 • Secondly, results are based on one year of health administrative data which depicts a  
44  
45 point in time and also only represents elements of care that are funded by the Ontario  
46  
47 Ministry of Health and Long-Term care; other important aspects of primary care are not  
48  
49 accounted for.  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

- Lastly, quality indicators are proxies for delivery of care; therefore, some of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.

**Key Words:** medical regulation, physician performance, licensure, quality of care, primary care, family medicine

**The primary care performance of alternatively licensed physicians in Ontario, Canada:  
A cross-sectional study using administrative data**

A safe and effective healthcare system relies on high quality physician performance. Medical Regulatory Authorities (MRAs) support such performance by issuing licenses to qualified physician applicants and monitoring those physicians once in practice to ensure their continued competence. MRAs also play a role in examining factors that influence physician performance as a way of identifying physician subgroups that may benefit from educational support.(1–8) Additionally, there has been discussion about the efficacy of regulatory processes for serving professional and public interests (9–11) and calls for evidence-informed regulation through the evaluation of regulatory processes and programs.(11–14) This study heeds such a call by examining the primary care performance of family physicians in Ontario as a way of evaluating regulatory licensure policies and exploring the influence of licensure route on physician performance.

In Canada, physicians traditionally complete a Canadian residency program and the Canadian qualifying and certification examinations to be granted a license to practice. However, in response to projected physician shortages in the early 2000s, many Canadian MRAs developed alternative licensing criteria to facilitate the licensure of physicians who do not meet the traditional criteria.(15,16) Alternative licensure routes were developed, primarily for International Medical Graduates (IMGs), based on previous experience or licensure, postgraduate training, and/or eligibility to write the Canadian certification exams.(15) Often, these physicians were recruited to work in specific underserved areas and given provisional licenses to practice despite not meeting the traditional qualifications.(17) Smaller Canadian provinces, such as Newfoundland and Saskatchewan, have been prominent issuers of provisional

1  
2  
3 licenses due to their longstanding health human resource needs;(18,19) however, provisionally  
4 licensed physicians often move to other parts of the country after completing their service terms,  
5  
6 as most are able to practice anywhere in Canada once licensed.(16–20) As such, it is thought that  
7  
8 smaller provinces may serve as entry points to larger provinces such as Ontario.(17,18)  
9

10  
11 In addition to the migration of provisionally licensed physicians across Canada, alternative  
12  
13 licensure routes also allow entry of physicians from the US into Canada and the licensure of  
14  
15 physicians who completed Canadian residency but did not immediately write or pass the national  
16  
17 certification exams. In these cases, provisional licenses are given with the stipulation of  
18  
19 successful exam completion within three years. Although these routes were initially developed to  
20  
21 increase access for IMGs, they are now also utilized by Domestic Medical Graduates (DMGs)  
22  
23 who have not successfully completed exams at the time of licensure.  
24  
25  
26  
27  
28  
29

30 Collectively, Alternatively Licensed Physicians (ALPs) represent physicians who did not meet  
31  
32 the licensure criteria at the time of entering independent practice in a given province but who  
33  
34 were considered to have comparable qualifications to Traditionally Licensed Physicians (TLPs),  
35  
36 based on their postgraduate training and/or professional experience. The performance of ALPs in  
37  
38 practice, however, has not been previously examined. Given that many ALPs are IMGs, a review  
39  
40 of IMG literature may offer insight into ALP practice performance; however, research  
41  
42 comparing IMGs and DMGs has been equivocal. Some studies show IMGs perform less well  
43  
44 than DMGs on certification and licensing examinations,(21–24) and that such performance is  
45  
46 associated with practice performance. (5,25) Yet, IMGs and DMGs have been shown to be  
47  
48 comparable on practice outcomes such as patient mortality,(26,27) readmission rates,(27)  
49  
50 surgical outcomes,(28) and cardiac care.(29)  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 While these conflicting findings may reflect the different outcomes being measured, they may  
4 also stem from the limited definition of IMG being employed. IMGs are typically defined by and  
5 compared on the location of their undergraduate medical training, but this only represents one  
6 step in an often long and diverse path of training and experience to independent practice.(15)  
7  
8 Examining physicians as defined by later steps in this process, such as point of licensure, may  
9 shed light on the impact of postgraduate medical training and early career practice experiences  
10 on subsequent performance and how physicians entering practice through alternative licensure  
11 routes may be better supported at different stages of their career.

19  
20  
21

22 In this study, we sought to understand the impact of alternative licensure routes on the delivery  
23 of primary care in Ontario. We used primary care quality indicators derived from health  
24 administrative data that were developed and validated by health services researchers to examine  
25 physician performance in areas such as chronic disease management, screening rates, and  
26 hospital readmissions using accepted practice guidelines.(30,31) We focused on the performance  
27 of a cohort of family physicians licensed through three main alternative routes: those licensed in  
28 another Canadian province, those licensed in the US, and those who trained in Canada but did  
29 not complete certifying examinations at the time of licensure. The research question guiding this  
30 study was: Does licensure route influence the primary care performance of physicians in  
31 Ontario?

1  
2  
3 The objective of this study was to examine the independent contribution of being licensed  
4 through various alternative routes on primary care performance. Given that licensure route has  
5 not been previously studied as a potential factor influencing performance, we were interested in  
6 isolating its effect by comparing each ALP group to TLPs on a variety of quality care indicators  
7 while adjusting for a number of covariates. We do not address the independent impact of the  
8 other variables that were adjusted for, as, practically, we could either focus on a small number of  
9 outcomes and explore the full multivariable models, or examine a broad spectrum of indicators  
10 representative of general family practice and narrow our focus to licensure route. We chose the  
11 latter, as we were interested in primary care performance as a whole rather than performance on  
12 any individual quality indicators. Additionally, the indicators do not have validated thresholds or  
13 gold standard rates at the individual- or population-level, thus performance is better assessed  
14 globally as opposed to focusing on individual tests, screens, or prescriptions. By focusing on the  
15 independent contribution of licensure route while adjusting for covariates, we aimed to  
16 understand if a physician's licensure route is associated with subsequent performance,  
17 irrespective of other demographic or practice characteristics. The goal of this approach was to  
18 explore whether regulatory licensure policies independently influence the primary care provided  
19 to patients in Ontario, thus offering evaluative evidence for the impact and outcomes of these  
20 policies.

Physicians (TLPs) and Alternatively Licensed Physicians (ALPs). TLPs are physicians who obtained a license to practice by meeting the traditional criteria, namely the completion of postgraduate training in Canada and successful completion of the national qualifying and certification examinations (the Medical Council of Canada Qualifying Examinations part 1 and 2, and either the College of Family Physicians of Canada (CFPC) or the Royal College of Physicians and Surgeons of Canada (RCPSC) exams). ALPs are those physicians who were missing one or more of the traditional requirements but met an alternative set of criteria at the time of licensure. There are many alternative licensure routes; in this study, we have focused on the three most commonly used by family physicians, described in Table 1. A more comprehensive description of these routes has been described previously.<sup>(15)</sup>

Table 1. Description of Alternatively Licensed Physician (ALP) subgroups

Out-of-Province ALPs	Physicians who obtained a license in another Canadian province and thus were given an equivalent license in Ontario despite missing one or more traditional licensing requirements <sup>1</sup> or who gained eligibility to write the CFPC examinations by gaining two years of practice experience in another Canadian province and were thus eligible for a provisional license in Ontario <sup>2</sup>
US-Trained ALPs	Physicians who completed postgraduate training in the US but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2,3</sup>
Canadian-Trained ALPs	Physicians who completed postgraduate training in Canada but had not successfully completed the Canadian certification examinations at the time of licensure <sup>2</sup>

<sup>1</sup> *The Agreement on Internal Trade is an interprovincial agreement that was incorporated into Ontario legislation enabling physicians migrating from other Canadian provinces be granted equivalent licenses to practice without assessment or examination*

<sup>2</sup> *Physicians are granted restricted (provisional) licenses and have up to three years to write the Canadian certification examinations*

<sup>3</sup> *Physicians may be granted restricted (provisional) licences due to successful completion of a practice assessment*

## Data Sources

Ontario health administrative datasets held at the Institute for Clinical Evaluative Sciences (ICES) were used in this study. These datasets were linked using unique encoded identifiers and analyzed at ICES under data security and privacy policies and procedures that are approved by the Office of the Information and Privacy Commissioner of Ontario.<sup>(32)</sup> The following administrative databases were used: Canadian Institute for Health Information hospital Discharge Abstract Database (CIHI-DAD, providing diagnostic information regarding hospital admissions), OHIP physician claims database (containing physician billings and diagnoses from 1991), the National Ambulatory Care Reporting System (NACRS) database (providing information on hospital- and community-based ambulatory care, including emergency department visits, from 2000 and same-day surgery from 1991), and the Ontario Drug Benefit (ODB) program database (containing information on all drug therapies dispensed to eligible individuals 65 years of age and older).

## Variables

Physician demographic characteristics included age, sex, medical school region, and the Human Development Index (HDI) associated with the physician's country of medical school, which is a composite score based on life expectancy, education, and per capita income that rank orders all countries.<sup>(33)</sup> Physician practice characteristics included practice type (comprehensive or not), group type (Family Health Team (FHT), non-FHT, no group), scope of practice (percent providing any of the following: postnatal visits, obstetrical deliveries, postnatal visits, emergency department (ED) visits, long term care (LTC) visits), and practice location (urban, suburban/rural). Comprehensive family physicians are those who met specific criteria regarding

1  
2  
3 the type and scope of services they provide.<sup>(34)</sup> FHTs are group practices which include  
4 comprehensive family physicians working alongside primary providers such as nurses, social  
5 workers, pharmacists and nutritionists. A detailed description of the physician demographic and  
6 practice characteristics is included in Appendix A.  
7  
8  
9  
10  
11

12  
13 Primary care quality indicators based on health administrative data were calculated for chronic  
14 disease management, preventive pediatric care, cancer screening, and hospital readmission rates.  
15 Chronic disease management indicators included measures for diabetes care (HbA1C testing,  
16 cholesterol testing, ophthalmology examinations, the receipt of prescriptions for angiotension  
17 converting enzyme inhibitors (ACE) and angiotensin II receptor blockers (ARBs)), congestive  
18 heart failure (CHF; echocardiogram testing within 12 months of diagnosis, emergency  
19 department (ED) visits), asthma (spirometry testing within 12 months of diagnoses, ED visits)  
20 and Chronic Obstructive Pulmonary Disease (COPD; spirometry testing within 12 months of  
21 diagnoses, ED visits). Pediatric care indicators include well-baby visits, the 18-month enhanced  
22 developmental assessment, and the absence of pediatric vaccinations (defined as no billing for  
23 any immunization in OHIP). Cancer screening indicators included cervical, breast, and colorectal  
24 cancer screening. Hospital readmission rates were calculated at 30 days and one year for patients  
25 with a hospital admission. These primary care quality indicators are described in Appendix B.  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43

44 For each family physician, patients who were either rostered (enrolled) or virtually rostered to  
45 them (attributed to the physician based on the majority of their billings) were included. All  
46 outcomes denote whether a patient received a given type of care, rather than whether the  
47 physician they were rostered to provided it. Therefore, patients who received care from a  
48 physician other than their family physician (e.g., a walk-in clinic physician or another family  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

physician in their practice) would appear in the data as having received that care and this would be attributed to the family physician they are rostered to.

## Statistical Analysis

Demographic and practice characteristics are presented as proportions, means, percentage with any, and mean percentages (Table 2). Absolute rates for the primary care quality indicators are presented as means and mean percentages unless otherwise noted (Table 3). Unadjusted rates are included for comprehensiveness but only the adjusted rates are discussed to answer our research question. Confidence limits (CL) are presented where applicable. To help with interpretation of results, statistically significant differences less than 5% were considered small and statistically significant differences greater than 5% were considered larger.

Our multivariable analysis modelled the relationship between physician licensure cohort (ALP group or TLP) and clinical practice outcomes. Before carrying out the modelling, we tested the outcome measures for normality and found that many, such as the proportion of a physician's diabetic patients who received an eye exam within the previous year, were not normally distributed, but became so after being log transformed. Based on this, we chose to use proc genmod in SAS to model the number with each characteristic (rather than the proportion) based on the Poisson distribution and including a log offset. Exponentiating the resulting parameter estimate gave us the relative rate for each outcome.

Each outcome was modeled individually. Covariates were entered into each model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income

1  
2  
3 and the median age of their patients. The relative rates estimated by the models indicate the  
4  
5 difference in outcome between each ALP group and the TLPs (reference group). All analyses  
6  
7 were conducted using SAS version 9.3. Ethical approval for this study was received from the  
8  
9 Sunnybrook Health Sciences Ethics Review Board.  
10  
11  
12

### 13 **Patient and Public Involvement**

14  
15  
16 There was no patient or public involvement in this study.  
17  
18  
19

## 20 **RESULTS**

### 21 **Demographic and Practice Characteristics**

22  
23 A total of 292 ALPs and 11,127 TLPs were included in the study (Table 2). The largest group of  
24  
25 ALPs were the Canadian Trained (n=114), followed by the US-Trained (n=91) and the Out-of-  
26  
27 Province (n=78). The majority of TLPs were men (56.6%) and were older (50.6 years) than all  
28  
29 three groups of ALPs. TLPs had fewer IMGs (22.2%) and overwhelmingly came from countries  
30  
31 with very high HDI (90.5%). All ALPs were slightly more likely than TLPs to be in  
32  
33 comprehensive practice and were less likely to be working in a FHT. Patient age and income  
34  
35 distributions were similar across all groups.  
36  
37  
38  
39  
40  
41  
42

43 The ALP groups' average ages ranged from 42.1 to 50.6 years. The Out-of-Province ALPs had  
44  
45 the highest proportion of men (69%) compared to the other ALP groups. In the Out-of-Province  
46  
47 ALP group, the majority were IMGs (89.7%) and completed medical school in countries  
48  
49 considered medium/low on the HDI (63.2%). Seventy percent (70.1 %) practised in urban  
50  
51 environments and they had the largest proportion in solo practice (32.2%). Similar to Out-of-  
52  
53 Province, the US-Trained ALPs were mostly IMGs (85.7%); however, they graduated primarily  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 from medical schools from countries with a very high/high HDI (68.1%). They had the largest  
4 proportion practising in non-FHT groups (65.9%) and were the most urban group (78%).  
5

6  
7  
8 Contrary to the other ALPs, almost half (47.4%) of the Canadian Trained ALPs were non-IMGs  
9  
10 and 72.9% came from countries with very high/high HDI. Seventy percent were in  
11  
12 comprehensive practice and they had the lowest percentage in solo practice. They also had the  
13  
14 lowest proportion practising in urban areas compared to all other groups (67.5%).

### Primary Care Quality Indicators

Table 3 shows the results of the unadjusted and adjusted comparisons between each ALP group and the TLPs (unadjusted mean numbers are included in Appendix C). Each ALP group had a unique profile of primary care quality indicators. Patients of the Out-of-Province ALPs had the most substantial statistically significant differences in the quality care indicators compared to patients of TLPs after multivariable adjustments. These family physicians' diabetic patients were 4% less likely to have received HbA1C testing and their COPD patients were 18% less likely to have received spirometry testing. Their patients with CHF, COPD or asthma were 7% more likely to visit an ED for any reason (i.e., all-cause) than those of TLPs. Additionally, their female patients aged 50-69 were 4% less likely to have received a mammogram in previous two years and their pediatric patients had 14% fewer well-baby visits, were 24% less likely to have had an 18-month enhanced well-baby visit, and were 38% more likely to have received no immunizations. However, their patients were 3% more likely to have received spirometry testing, 4% more likely to receive colon cancer screening, and their hospitalized patients were 9% less likely to be readmitted in one year.

In contrast, US-Trained ALPs were comparable to their TLP counterparts, with some statistically significant differences. Their diabetic care and cancer screening rates were similar, although US-Trained ALP patients were 8% more likely to have received HbA1c and lipids testing than TLPs' patients and 2% more likely to have received a pap test or any colon cancer screening. Their CHF, COPD and asthma patients were also 3% less likely to visit the ED and their pediatric patients were 27% less likely to have not received any immunizations; however, they were 7% less likely to receive well-baby visits. Canadian Trained ALPs were also similar to their TLP counterparts across most indicators; however, some statistically significant differences were

1  
2  
3 seen: their pediatric patients were 3% less likely to have received a well-baby visit but were 34%  
4  
5 less likely to have not received any childhood immunizations; their COPD patients were 11%  
6  
7 less likely to have had spirometry testing within 12 months of diagnosis; and their patients with  
8  
9 CHF, COPD or asthma were 9% more likely to visit an ED (all-cause) than those of TLPs. Minor  
10  
11 differences were seen also seen with HbA1c testing, spirometry testing for asthma patients, and  
12  
13 colon cancer screening, with Canadian-Trained ALP's patients being 3% more likely to have  
14  
15 received testing or screening.

## DISCUSSION

Our analysis of primary care quality indicators suggest that alternatively licensed physicians (ALPs) perform similarly to traditionally licensed physicians (TLPs) in many areas of primary care practice when controlling for a number of covariates. Small differences were seen across groups in indicators of diabetic care, CHF care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age and COPD management, particularly in patients of Out-of-Province ALPs. While individual family physician performance is contextual and influenced by many factors,<sup>(6,35)</sup> health administrative data is useful for gaining a system-level impression of family physicians' quality of care and broadly identifying areas that may need improvement.<sup>(36)</sup> Over all, our findings suggest that alternative licensure route is not a strong independent predictor of family medicine performance on the majority quality indicators examined. For a small number of newly licensed family physicians, educational content pertaining to Ontario-specific guidelines and expectations may be of benefit.

### Out-of-Province ALPs

Compared to other subgroups, the primary care performance of Out-of-Province ALPs was the most different from TLPs after adjustments. Most notably, their patients less than two years of age were significantly less likely to receive well baby visits, enhanced 18-month assessments, or immunizations, highlighting a trend in preventive pediatric care. These differences may reflect provincial differences in guidelines and schedules for pediatric care. For example, there is significant variation in how 18-month assessments are approached globally and across Canada.<sup>(37)</sup> Ontario has supported a longer and more comprehensive enhanced 18-month

1  
2  
3 assessment by providing financial incentives through a unique billing code.(37–39) It is possible  
4 that Out-of-Province ALPs were unaware of Ontario’s enhanced 18-month assessment or of the  
5 pediatric care expectations of family physicians in the province. It is also possible that these  
6 physicians provided 18-month assessments but did not bill for it using the Ontario-specific code.  
7  
8 Previous research has shown that male IMGs who have been in practice for over 10 years are  
9 less likely to provide 18-month assessments in Ontario.(40) In this study, age, gender, and HDI  
10 were controlled for, suggesting these factors are not accountable for the differences; thus,  
11 entering Ontario from another province through an alternative route appears to be an independent  
12 risk factor.  
13  
14

15 Similar to the differences seen in 18-month assessments, the lower childhood immunization rates  
16 in the Out-of-Province ALPs may be in part due to inter-provincial variation in policies. For  
17 example, childhood vaccine schedules differ across provinces (41) which may have implications  
18 for how physicians bill. Further, in Ontario, immunizations for children under two years of age  
19 are predominantly done in physician offices,(42) while they may be administered by nurses or  
20 other allied health professionals in other provinces. Thus, the norms and conventions from their  
21 prior jurisdictions may be reflected in the billing practices of these ALPs once in Ontario.  
22  
23

24 In addition to differences in preventive pediatric care, Out-of-Province ALPs differed from TLPs  
25 in rates of spirometry testing for COPD patients, which is recommended to confirm a diagnosis  
26 of COPD.(43–46) Previous research has found that spirometry test ordering among family  
27 physicians in Ontario is generally low,(47) and our findings suggest that it is even lower among  
28 Out-of-Province ALPs (and Canadian Trained ALPs) compared to TLPs, highlighting potential  
29 provincial differences in utilization. Out-of-Province ALPs’ patients with CHF, COPD, or  
30 asthma also had higher rates of all-cause ED visits, but their hospitalized patients were 9% less

likely to have been readmitted within one year. Rates of all-cause ED visits and readmissions are sometimes associated with access to primary care,(48–51) but can be influenced by many factors (51–54) and should thus be interpreted cautiously.

Overall, our findings highlight that ALPs entering Ontario from another Canadian province perform differently than TLPs in certain indicators of primary care. However, the performance differences noted in this study may be due to provincial differences in care expectations and reflect the context of their recent work environments. Such provincial differences in how physicians provide primary care have implications for the migration of physicians across provinces since physicians can typically practice anywhere in Canada once licensed. Given that provisional licenses have been seen as a way for physicians to gain entry to larger provinces through smaller ones,(17) the Federation of Medical Regulatory Authorities of Canada has begun to standardize provincial licensure requirements and the Medical Council of Canada is facilitating a common approach to practice ready assessments for IMGs across the country. While these efforts will help to mitigate potential performance differences in Canadian physicians, our findings suggest that ALPs entering Ontario from another province may still benefit from information about Ontario care expectations at the time of licensure. Focused knowledge translation for family physicians migrating across provinces may help to educate physicians about province-specific expectations and support their adoption of provincially-supported programs and guidelines, reducing the potential for future performance differences.

### **US-Trained and Canadian-Trained ALPs**

US-Trained and Canadian-Trained ALPs performed similarly to TLPs on most primary care quality indicators after adjustments, though some notable differences were seen. For both groups,

1  
2  
3 patients less than two years of age were less likely to receive well baby visits but more likely to  
4 receive immunizations. In contrast to the Out-of province ALPs, whose patients were more likely  
5 to have not received any early childhood immunizations, US- and Canadian-Trained ALP  
6 patients were much more likely to receive them compared to the rest of the province: this 27-  
7 34% difference was the largest difference seen between these groups and the TLPs. US-Trained  
8 ALPs' patients were also more likely to receive pap tests and colon cancer screenings, their  
9 diabetic patients were more likely to receive HbA1c and lipid testing, and their patients with  
10 CHF, COPD, or asthma were less likely to visit an ED. The higher rates of testing and screening  
11 may be reflective of their American training, as previous research has found American  
12 physicians tend to have lower thresholds for diagnostic and therapeutic interventions.(55) Similar  
13 to Out-of-Province ALPs, Canadian-Trained ALPs' COPD patients were less likely to receive  
14 spirometry testing, and their patients with CHF, COPD, or asthma were more likely to visit an  
15 ED. Overall, the performance of both of these ALP groups was comparable to TLPs. This is  
16 perhaps unsurprising given that these physicians have similar postgraduate training, and that  
17 postgraduate training has been found to be predictive of patient outcomes.(56) Our findings  
18 provide evidence that their practice performance is in fact similar to traditionally licensed  
19 physicians in Ontario.

## 42 **Conclusions**

43  
44  
45  
46 Our findings illustrate that ALPs perform similarly to TLPs across many indicators of primary  
47 care, suggesting that route of licensure is not a strong predictor of family physician performance  
48 in Ontario. These findings provide support for alternative licensure policies and also demonstrate  
49 the utility of health administrative data for examining physician performance and evaluating  
50 regulatory processes. As transparency and accountability are increasingly emphasized in

healthcare,(57) and as physician migration and the use of alternative licensure routes continues to increase,(15) it is imperative that processes for licensing and monitoring physicians are rigorously evaluated. The ongoing assessment of physician performance is critical for understanding the effects of medical regulatory policies and, ultimately, for ensuring high quality patient care.

### **Strengths and Limitations**

This is the first study to examine the primary care performance of alternatively and traditionally licensed family physicians in Ontario. Our use of population-level data across multiple indicators of primary care allowed for a robust and comprehensive comparison of ALPs and TLPs and our use of multivariable analysis enabled statistical adjustment of physician demographics, practice environments, and patient factors, such as SES, that are associated with primary care performance. While this approach contributes to our understanding of ALP performance, it is not without limitations. First, ALPs and TLPs were compared to each other, not to a gold standard. As such, our findings do not indicate whether physicians are meeting performance benchmarks, but rather whether ALP performance is comparable to TLP performance. Second, our results are based on one year of health administrative data which depicts a point in time and also only represents elements of care that are funded by the Ontario Ministry of Health and Long-Term care. Other important aspects of primary care such as the doctor-patient relationship or inter-professional collaboration with other primary health care providers are thus not accounted for. Last, billing data introduces unique interpretation challenges as these quality indicators are proxies for delivery of care; therefore, some of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.

### Implications for Future Research

This study offers insight into the primary care performance of alternatively licensed physicians. Primary care is an important area of study given that approximately half of physicians in Ontario specialize in Family Medicine;(15) however, future research is needed to examine the practice performance of ALPs practicing in other specialties. Performance is also multi-faceted and must be studied using a variety of measures. Future studies could include other measures of performance, such as practice assessments or complaints profiles, to gain a comprehensive picture of ALPs' practices.

This study also demonstrates that licensure route is a useful way of stratifying and comparing physicians. IMG studies typically define physicians based on their country of undergraduate medical school, whereas licensure route accounts for the influence of postgraduate training and previous practice experience on performance. Examining the impact of all of a physician's training and experience on future practice performance allows for a more robust understanding of the predictors of performance and may enable more nuanced IMG research in the future.

Finally, this study represents a collaboration between a medical regulator and system partners. Such collaborations are important for linking performance data across the continuum of medical education and practice (58,59) and for providing evaluative evidence for regulatory processes and policies, such as alternative licensure routes.(12,14) Further collaborations of this nature will allow for robust examinations of the influence of each stage of a physician's training on future practice performance.

## Declarations

1. Ethics approval: Ethical approval for this study was obtained from the Sunnybrook Health Sciences Center Ethics Review Board
2. Availability of data and material: The datasets included in this study are housed at the Institute for Clinical Evaluative Sciences. A request to the Data Analytic Services (DAS) at ICES is required in order to obtain access to data or analytic services ([www.ices.on.ca/DAS/Data](http://www.ices.on.ca/DAS/Data)).
3. Conflicts of interests: The authors declare that they have no conflicts of interests
4. Funding: The analysis for this study was funded by an annual grant to the Institute for Clinical Evaluative Sciences from the Ontario Ministry of Health and Long-Term Care (MOHLTC)
5. Author contributions: KH, NT, DF, and WY conceptualized this study, interpreted the data, and were key contributors to the manuscript. LJ and SS were responsible for selecting and operationalizing the outcome measures. SS analyzed the data and contributed to writing the manuscript. All authors read and approved the final manuscript.
6. Author information: KH is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Health Services Research from the University of Toronto; NT is a Research Associate at the College of Physicians and Surgeons of Ontario and has an MSc in Kinesiology and Health Science from York University; SS is a Senior Epidemiologist at the Institute for Clinical Evaluative Sciences and has an MA in Regional Planning from the University of Waterloo and an MSc in Community Health and Epidemiology from the University of Toronto; LJ is a Senior Scientist at the Institute for Clinical Evaluative Sciences and has an MSc in Community Health and Epidemiology from Queen's University

1  
2  
3 and an MD from McMaster University; DF is the Deputy Registrar at the College of  
4  
5 Physicians and Surgeons of Ontario and has an MBA in Health Services Management from  
6  
7 McMaster University; WY is a Senior Researcher at the College of Physicians and Surgeons  
8  
9 of Ontario and has an MA in Measurement and Evaluation from the University of Toronto  
10  
11 and is currently pursuing a PhD in Adult Education from the University of Toronto.

**Appendix A) Description of Physician Demographic and Practice Characteristic Indicators**

<b>Indicator</b>	<b>Description</b>	<b>Definition of indicator</b>
<i>Sex</i>		
<i>Male</i>	Physician sex	Male sex
<i>Female</i>		Female sex
<i>Age</i>	Physician age	Physician age in 2014
<i>HDI Group</i>	2013 Human development index associated with the country of undergraduate medical school of physician (26)	
<i>Very high</i>		HDI rank < 50
<i>High</i>		HDI rank ≥50 and < 103
<i>Medium</i>		HDI rank ≥103 and < 145
<i>Low</i>	HDI rank ≥145	
<i>Practice Type</i>		
<i>Comprehensive</i>	Comprehensive practice is if majority of services billed are related to “core primary care” and span multiple practice areas (27)	≥ 44 days worked/yr and > 50% of billing “in core primary care” in at least 7 of 22 practice areas
<i>Other</i>		All other FM physicians
<i>Group type</i>		
<i>FHT</i>	Family Health Team, group practice but not-Family Health Team or solo practice	
<i>non-FHT</i>		
<i>No group</i>		
<i>Rurality</i>		
<i>Urban</i>	Practice location categorized in to urban or suburban/rural based on 2008 Rurality Index for Ontario (RIO) score (50)	RIO < 10
<i>Suburban/Rural</i>		RIO ≥ 10
<i>Scope of practice</i>		
<i>Prenatal visits</i>	If the physician submitted billing for care related to: prenatal	% with any billing

1136/bmjopen-2019-022299 on June 11, 2019. Downloaded from <http://bmjopen.bmj.com/> on April 20, 2024 by guest. Protected by copyright.

<i>Obstetrical Delivery</i>	visits, obstetrical delivery, postnatal visits, Emergency	% with any billing
<i>Postnatal visits</i>	Department, or Long-Term Care	% with any billing

**Appendix B) Description of Primary Care Quality Indicators**

<b>Indicator</b>	<b>Population</b>	<b>Description/guideline</b>	<b>Definition of indicator</b>
<i>Diabetes</i>			
<i>HbA1c</i>		Every 3-6 months, depending on control (51)	2+ HbA1c in previous 12 months
<i>Eye exam</i>		Examination every 1-2 years, depending on severity (51)	Eye exam in previous 24 months
<i>Lipids</i>	Pts with Diabetes Mellitus	Total cholesterol, HDL-C, LDL-C, and TGs annually (51)	1+ cholesterol test in previous 12 months
<i>ACE/ARB</i>		Indicated for pts with high cardiovascular risk (51)	Prescribed ACE/ARB in previous 12 months (pts >65 years of age or older)
<i>Statin</i>		Indicated for pts with elevated lipids (51)	Prescribed statin in previous 12 months (pts >65 years of age or older)
<i>CHF</i>			
<i>Echocardiogram w/in 12 mths of diagnosis</i>	Pts with newly diagnosed CHF	Recommended early after CHF diagnosis for assessment and management (52)	Echocardiogram ordered within 12 months of diagnosis
<i>ED visits/person</i>	Pts with CHF		All cause ED visit in 2014/15
<i>COPD</i>			
<i>Spirometry w/in 12 mths of diagnosis</i>	Pts with newly diagnosed COPD	Recommended for diagnosis (37)	Spirometry within 12 months of diagnosis
<i>ED visits/person</i>	Pts with COPD	All COPD pts, number of ED visits/year	All cause ED visit in 2014/15

<i>Asthma</i>			
<i>Spirometry</i>		Recommended to be reassessed regularly and used for diagnosis (53)	Ever had spirometry
<i>ED visits/person</i>	Pts with asthma	All asthma pts number of ED visits/year	All cause ED visit in 2014/15
<i>Preventive Pediatric Care</i>			
<i>Well-baby visits</i>	Pts < 2yrs		Number of visits in first 24 months
<i>18-month enhanced well baby visit</i>	Pts 18 months	Recommended for every child in Ontario (32)	Submitted 18 month billing code
<i>No Immunization</i>	Pts < 2yrs	Publicly funded routine immunizations for children in first 2 yrs (54)	Submitted no billing codes for DTAP, Pneumococcal, MenCC, MMR, Varicella
<i>Cancer Screening</i>			
<i>Mammogram</i>	Female pts 52-69 yrs (excluding breast cancer pts)	Recommended every 2-3 years for pts 50-69 (55)	Mammogram in previous 24 months
<i>Pap test</i>	Female pts 23-69 yrs (excluding cervical and endometrial cancer pts)		Pap in previous 36 months
<i>All colon cancer screening</i>	Pts 52-74 yrs (excluding colon cancer and IBD pts)	FOBT recommended every 1-2 yrs; Colonoscopy every 10 yrs; Flexible Sigmoidoscopy and Double Contrast Barium Enema every 5years for pts 50-74	Any FOBT in previous 2 yrs; colonoscopy in previous 10 yrs; other in previous 5 yrs

STROBE Statement—checklist of items that should be included in reports of observational studies  
**NOTE: Page Numbers refer to “clean” (i.e. unmarked) version of manuscript**

	Item No.	Recommendation	Page No.	Relevant text from manuscript
<b>Title and abstract</b>	1	(a) Indicate the study’s design with a commonly used term in the title or the abstract	1	The primary care performance of alternatively licensed physicians in Ontario, Canada: A cross-sectional study using administrative data
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	3-4	A cross-sectional retrospective examination of Ontario health administrative data was conducted using Poisson regression analyses to compare the performance of traditionally and alternatively licensed physicians. Minimal differences were seen across groups in indicators of diabetic care, congestive heart failure care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age, particularly for alternatively licensed physicians who entered Ontario from another Canadian province.
<b>Introduction</b>				
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	7-8	Collectively, Alternatively Licensed Physicians (ALPs) represent physicians who did not meet the licensure criteria at the time of entering independent practice in a given province but who were considered to have comparable qualifications to Traditionally Licensed Physicians (TLPs), based on their postgraduate training and/or professional experience. The performance of ALPs in practice, however, has not been previously examined. Given that many ALPs are IMGs, a review of IMG literature may offer insight into ALP practice performance; however, research comparing IMGs and DMGs has been equivocal. IMGs are typically defined by and compared on the location of their undergraduate medical training, but this only represents one step in an often long and diverse path of training and experience to independent practice. Examining physicians as defined by later steps in this process, such as point of licensure, may shed light on the impact of postgraduate medical training and early career practice experiences on subsequent performance and how physicians entering practice through alternative licensure routes may be better supported at different

				stages of their career
Objectives	3	State specific objectives, including any prespecified hypotheses	8	The research question guiding this study was: Does licensure route influence the primary care performance of physicians in Ontario?
<b>Methods</b>				
Study design	4	Present key elements of study design early in the paper	9	In order to isolate the effect of licensure route, we chose to compare each ALP group to TLPs while adjusting for a number of covariates. We do not address the independent impact of the other variables that were adjusted for, as we felt we could either focus on a small number of outcomes and explore the full multivariable models, or examine a broad spectrum of indicators representative of general family practice and narrow our focus to licensure route. We chose the latter, as we were interested in primary care performance as a whole rather than performance on any individual quality indicators.
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
Participants	6	<i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
		<i>(b) Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case		NA
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	11-12 and supplementary file	Physician demographic characteristics included age, sex, medical school region, and the Human Development Index (HDI) associated with the physician's country of medical school, which is a composite score based on life expectancy, education, and per capita income that rank orders all countries. <sup>(13)</sup> Physician practice characteristics included practice type (comprehensive or not), group type (Family Health Team (FHT), non-FHT, no group), scope of practice (percent providing any of the following: postnatal visits, obstetrical deliveries, postnatal visits, emergency department (ED) visits, long term care (LTC) visits), and practice location (urban, suburban/rural). Comprehensive family physicians are

those who met specific criteria regarding the type and scope of services they provide.(34) FHTs are group practices which include comprehensive family physicians working alongside primary providers such as nurses, social workers, pharmacists and nutritionists. A detailed description of the physician demographic and practice characteristics is included in Appendix A.

Primary care quality indicators based on health administrative data were calculated for chronic disease management, preventive pediatric care, cancer screening, and hospital readmission rates. Chronic disease management indicators included measures for diabetes care (HbA1C testing, cholesterol testing, ophthalmology examinations, the receipt of prescriptions for angiotension converting enzyme inhibitors (ACE) and angiotensin II receptor blockers (ARBs)), congestive heart failure (CHF; echocardiogram testing within 12 months of diagnosis, emergency department (ED) visits), asthma (spirometry testing within 12 months of diagnoses, ED visits) and Chronic Obstructive Pulmonary Disease (COPD; spirometry testing within 12 months of diagnoses, ED visits). Pediatric care indicators include well-baby visits, the 18-month enhanced developmental assessment, and the absence of pediatric vaccinations (defined as no billing for any immunization in OHIP). Cancer screening indicators included cervical, breast, and colorectal cancer screening. Hospital readmission rates were calculated at 30 days and one year for patients with a hospital admission. These primary care quality indicators are described in Appendix B.

Ontario health administrative datasets held at the Institute for Clinical Evaluative Sciences (ICES) were used in this study. These datasets were linked using unique encoded identifiers and analyzed at ICES under data security and privacy policies and procedures that are approved by the Office of the Information and Privacy Commissioner of Ontario.(32) The following administrative databases were used: Canadian Institute for Health Information hospital Discharge Abstract Database (CIHI-DAD, providing diagnostic information regarding hospital admissions), OHIP physician claims database (containing physician billings and diagnoses from 1991), the National Ambulatory Care Reporting System (NACRS) database (providing information on hospital- and

Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	10-11
---------------------------	----	--	-------

For peer review only

				community-based ambulatory care, including emergency department visits, from 2000 and same-day surgery from 1991), and the Ontario Drug Benefit (ODB) program database (containing information on all drug therapies dispensed to eligible individuals 65 years of age and older)
Bias	9	Describe any efforts to address potential sources of bias	13	Covariates were entered into the model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income and the median age of their patients.
Study size	10	Explain how the study size was arrived at	9	The study population included all practising family physicians in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014.
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	11-12 and supplementary file	See item 7
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	13	Our multivariate analysis modelled the relationship between physician licensure cohort (ALP group or TLP) and clinical practice outcomes. Before carrying out the modelling, we tested the outcome measures for normality and found that many, such as the proportion of a physician's diabetic patients who received an eye exam within the previous year, were not normally distributed, but became so after being log transformed. Based on this, we chose to use proc genmod in SAS to model the number with each characteristic (rather than the proportion) based on the Poisson distribution and including a log offset. Exponentiating the resulting parameter estimate gave us the relative rate for each outcome. Each outcome was modelled individually. Covariates were entered into the model in a stepwise fashion, with only the significant variables retained in the final model. These included grouped age, sex, number of years in practice, urban-rural status, IMG status, whether the physician was in a patient enrollment model, HDI group, the proportion of their patients who were low income and the median age of their patients. The relative rates estimated by the model indicate the difference in outcome between each ALP group and the TLPs (reference group).
		(b) Describe any methods used to examine		NA

		subgroups and interactions		
		(c) Explain how missing data were addressed	9	The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 <b>and billed the Ontario Health Insurance Plan (OHIP) in 2014. All publicly funded health services provided by physicians are submitted to OHIP.</b>
		(d) <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy		NA
		(e) Describe any sensitivity analyses		NA
<b>Results</b>				
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	14 9	A total of 792 ALPs and 11,127 TLPs were included in the study  The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 and billed the Ontario Health Insurance Plan (OHIP) in 2014
		(b) Give reasons for non-participation at each stage		NA
		(c) Consider use of a flow diagram		NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	14-16	A total of 792 ALPs and 11,127 TLPs were included in the study (Table 2). The largest group of ALPs were the Canadian Trained (n=114), followed by the US-Trained (n=91) and the Out-of-Province (n=78). The majority of TLPs were men (56.6%) and were older (50.6 years) than all three groups of ALPs. TLPs had fewer IMGs (22.4%) and overwhelmingly came from countries with very high HDI (90.5%). All ALPs were slightly more likely than TLPs to be in comprehensive practice and were less likely to be working in a FHT. Patient age and income distributions were similar across all groups. The ALP groups' average ages ranged from 42.1 to 50.6 years. The Out-of-Province ALPs had the highest proportion of men (69%) compared to the other ALP groups. In the Out-of-Province ALP group, the majority were IMGs (89.7%) and completed medical school in countries considered medium/low on the HDI (63.2%). Seventy percent (70.1 %) practised in urban environments and they

					had the largest proportion in solo practice (32.2%). Similar to Out-of-Province, the US-Trained ALPs were mostly IMGs (85.7%); however, they graduated primarily from medical schools from countries with a very high/high HDI (68.1%). They had the largest proportion practising in non-FHT groups (65.9%) and were the most urban group (78%). Contrary to the other ALPs, almost half (47.4%) of the Canadian Trained ALPs were non-IMGs and 72.9% came from countries with very high/high HDI. Seventy percent were in comprehensive practice and they had the lowest percentage in solo practice. They also had the lowest proportion practising in urban areas compared to all other groups (67.5%).
		(b) Indicate number of participants with missing data for each variable of interest	9		The study population included <b>all practising family physicians</b> in Ontario who were registered with the College of Physicians and Surgeons of Ontario (CPSO) between 2000 and 2012 <b>and billed the Ontario Health Insurance Plan (OHIP) in 2014. <b>Discussion</b>				
Key results	18	Summarise key results with reference to study objectives	21	Our analysis of primary care quality indicators suggest that alternatively licensed physicians (ALPs) perform similarly to traditionally licensed physicians (TLPs) in many areas of primary care practice when controlling for a number of covariates. Small differences were seen across groups in indicators of diabetic care, CHF care, asthma care, and cancer screening rates. Larger differences were found in preventive care for children less than two years of age and COPD management, particularly in patients of Out-of-Province ALPs. While individual family physician performance is contextual and influenced by many factors,(6,35) health administrative data is useful for gaining a system-level impression of family physicians' quality of care and identifying areas that are meeting practice benchmarks and areas that may need improvement.(36) Over all, our findings suggest that alternative licensure route is not a strong independent predictor of family medicine performance on the majority quality indicators examined. For a small number of newly licensed family physicians, educational content pertaining to Ontario-specific guidelines and expectations may be of benefit.
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	26-27	First, ALPs and TLPs were compared to each other, not to a gold standard. As such, our findings do not indicate whether physicians are meeting performance benchmarks, but rather whether ALP performance is comparable to TLP performance. Second, our results are based on one year of health administrative data which depicts a point in time and also only represents elements of care that are funded by the Ontario Ministry of Health and Long-Term care. Other important aspects of primary care such as the doctor-patient relationship or inter-professional collaboration with other primary health care providers are thus not accounted for. Last, billing data introduces unique interpretation challenges as these quality indicators are proxies for delivery of care; therefore, some

				of the variance in the indicators may be, in part, attributable to differences in billing practices or factors unrelated to the physician, such as patient preference.
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	21-24	Compared to other subgroups, the primary care performance of Out-of-Province ALPs was the most different from TLPs after adjustments. Most notably, their patients less than two years of age were significantly less likely to receive well baby visits, enhanced 18-month assessments, or immunizations, highlighting a trend in preventive pediatric care. These differences may reflect provincial differences in guidelines and schedules for pediatric care. For example, there is significant variation in how 18-month assessments are approached globally and across Canada. Ontario has supported a longer and more comprehensive enhanced 18-month assessment by providing financial incentives through a unique billing code. It is possible that Out-of-Province ALPs were unaware of Ontario's enhanced 18-month assessment or of the pediatric care expectations of family physicians in the province. It is also possible that these physicians provided 18-month assessments but did not bill for it using the Ontario-specific code. Previous research has shown that male IMGs who have been in practice for over 10 years are less likely to provide 18-month assessments in Ontario. <sup>40</sup> In this study, age, gender, and HDI were controlled for, suggesting these factors are not accountable for the differences; thus, entering Ontario from another province through an alternative route appears to be an independent risk factor. Similar to the differences seen in 18-month assessments, the lower childhood immunization rates in the Out-of-Province ALPs may be in part due to inter-provincial variation in policies. For example, childhood vaccine schedules differ across provinces which may have implications for how physicians bill. Further, in Ontario, immunizations for children under two years of age are predominantly done in physician offices, while they may be administered by nurses or other allied health professionals in other provinces. Thus, the norms and conventions from their prior jurisdictions may be reflected in the billing practices of these ALPs once in

Ontario. In addition to differences in preventive pediatric care, Out-of-Province ALPs differed from TLPs in rates of spirometry testing for COPD patients, which is recommended to confirm a diagnosis of COPD. Previous research has found that spirometry test ordering among family physicians in Ontario is generally low, and our findings suggest that it is even lower among Out-of-Province ALPs (and Canadian Trained ALPs) compared to TLPs, highlighting potential provincial differences in utilization. Out-of-Province ALPs' patients with CHF, COPD, or asthma also had higher rates of all-cause ED visits, but their hospitalized patients were 9% less likely to have been readmitted within one year. Rates of all-cause ED visits and readmissions are sometimes associated with access to primary care, but can be influenced by many factors and should thus be interpreted cautiously.

Overall, our findings highlight that ALPs entering Ontario from another Canadian province perform differently than TLPs in certain indicators of primary care. However, the performance differences noted in this study may be due to provincial differences in care expectations and reflect the context of their recent work environments. Such provincial differences in how physicians provide primary care have implications for the migration of physicians across provinces since physicians can typically practice anywhere in Canada once licensed. Given that provisional licenses have been seen as a way for physicians to gain entry to larger provinces through smaller ones, the Federation of Medical Regulatory Authorities of Canada has begun to standardize provincial licensure requirements and the Medical Council of Canada is facilitating a common approach to practice ready assessments for IMGs across the country. While these efforts will help to mitigate potential performance differences in Canadian physicians, our findings suggest that ALPs entering Ontario from another province may still benefit from information about Ontario care expectations at the time of licensure. Focused knowledge translation for family physicians migrating across

provinces may help to educate physicians about province-specific expectations and support their adoption of provincially-supported programs and guidelines, reducing the potential for future performance differences. US-Trained and Canadian-Trained ALPs performed similarly to TLPs on most primary care quality indicators after adjustments, though some notable differences were seen. For both groups, patients less than two years of age were less likely to receive well baby visits but more likely to receive immunizations. In contrast to the Out-of-province ALPs, whose patients were more likely to have not received any early childhood immunizations, US- and Canadian-trained ALP patients were much more likely to receive them compared to the rest of the province: this 27-34% difference was the largest difference seen between these groups and the TLPs. US-Trained ALPs' patients were also more likely to receive pap tests and colon cancer screenings, their diabetic patients were more likely to receive HbA1c and lipid testing, and their patients with CHF, COPD, or asthma were less likely to visit an ED. The higher rates of testing and screening may be reflective of their American training, as previous research has found American physicians tend to have lower thresholds for diagnostic and therapeutic interventions. Similar to Out-of-Province ALPs, Canadian-Trained ALPs' COPD patients were less likely to receive spirometry testing, and their patients with CHF, COPD, or asthma were more likely to visit an ED. Overall, the performance of both of these ALP groups was comparable to TLPs. This is perhaps unsurprising given that these physicians have similar postgraduate training, and that postgraduate training has been found to be predictive of patient outcomes. Our findings provide evidence that their practice performance is in fact similar to traditionally licensed physicians in Ontario.

---

Generalisability	21	Discuss the generalisability (external validity) of the study results	26	This study offers insight into the primary care performance of alternatively licensed physicians. Primary care is an important area of study given that approximately half of physicians in Ontario specialize in Family Medicine;(15) however, future research is needed to examine the practice performance of ALPs practicing in other specialties. Performance is also multi-faceted and must be studied using a variety of measures. Future studies could include other measures of performance, such as practice assessments or complaints profiles, to gain a comprehensive picture of ALPs' practices.
