BMJ Open Meta-analysis: the effects of smoking on the disposition of two commonly used antipsychotic agents, olanzapine and clozapine

Yoshiyuki Tsuda,1 Junji Saruwatari,1 Norio Yasui-Furukori2

ABSTRACT

Objective: To clarify the effects of smoking on the disposition of two commonly used antipsychotics, olanzapine and clozapine, and to create standards to adjust the doses of these drugs in clinical practice based on the smoking status.

Design: A meta-analysis was conducted by searching MEDLINE, Scopus and the Cochrane Library for relevant prospective and retrospective studies.

Included studies: We included the studies that investigated the effects of smoking on the concentration to dose (C/D) ratio of olanzapine or clozapine.

Primary outcome measure: The weighted mean difference was calculated using a DerSimonian-Laird random effects model, along with 95% CI.

Results: Seven association studies, comprising 1094 patients (652 smokers and 442 non-smokers) with schizophrenia or other psychiatric disorders, were included in the meta-analysis of olanzapine. The C/D ratio was significantly lower in smokers than in non-smokers (p<0.00001), and the mean difference was −0.75 (ng/mL)/(mg/day) (95% CI −0.89 to −0.61). Therefore, it was estimated that if 10 and 20 mg/day of olanzapine would be administered to smokers, about 7 and 14 mg/day, respectively, should be administered to non-smokers in order to obtain the equivalent olanzapine concentration. Four association studies of clozapine were included in the meta-analysis of clozapine, comprising 196 patients (120 smokers and 76 non-smokers) with schizophrenia or other psychiatric disorders. The C/D ratio was significantly lower in smokers than in non-smokers (p<0.00001), and the mean difference was −1.11 (ng/mL)/(mg/day) (95% CI −1.53 to −0.70). Therefore, it was estimated that if 200 and 400 mg/day of clozapine would be administered to smokers, about 100 and 200 mg/day, respectively, should be administered to non-smokers.

Conclusions: We suggest that the doses of olanzapine and clozapine should be reduced by 30% and 50%, respectively, in non-smokers compared with smokers in order to obtain an equivalent olanzapine or clozapine concentration.

Strengthenes and limitations of this study

The major strength of this study is that it clarifies the effects of smoking on the olanzapine and clozapine concentrations in a large population and provides standards that can be used to regulate the dosage of olanzapine and clozapine in clinical practice based on the patient’s smoking status.

The major limitations of the present study are that we could not use another search engine, for example, EMBASE, and also we could not include the literature published in other languages (not in English) or the data regarding other confounding factors, such as the age, weight, gender, alcohol consumption and how much the participant smoked. Additionally, this meta-analysis standardised pharmacokinetic parameters to concentration to dose ratios, and therefore only seven studies for olanzapine and four studies for clozapine could be included.

INTRODUCTION

Olanzapine is an atypical antipsychotic drug approved for the treatment of schizophrenia and mania and for preventing the recurrence of bipolar disorders.1 Olanzapine is a thienobenzodiazepine derivate, which shows potent antagonism at D1-4 dopaminergic receptors, as well as 5-HT2A and 5-HT2C serotonergic, α1-adrenergic, muscarinic and H1 histamine receptors.2 Olanzapine is extensively metabolised in the liver, mainly via cytochrome P450 (CYP) 1A2, but also via CYP2D6, CYP3A4, flavin-containing monooxygenase (FMO) and glucuronidation.2 Among these enzymes, CYP1A2 accounts for approximately 50–60% of olanzapine metabolism.2 Clozapine is the prototype atypical antipsychotic, and it belongs to the chemical class of the dibenzodiazepines.1 Clozapine has much greater antagonistic activity on D4...
than D2 dopaminergic receptors. It also shows a potent antagonism of 5-HT2A and 5-HT2C serotonergic, α1-adrenergic, muscarinic and H1 histamine receptors. Clozapine has been widely used following its introduction, because it induces relatively few extrapyramidal effects, and it shows therapeutic benefits for patients who have failed to respond to other agents. Clozapine is absorbed rapidly and undergoes extensive hepatic metabolism. Various lines of evidence indicate that CYP1A2 and CYP3A4 play a significant role in the N-oxidation and N-demethylation of the compound, whereas CYP2D6 plays a minor role in N-demethylation.

The prevalence of smoking is twofold to threefold higher in patients with schizophrenia than in the general population, and about 58–88% of patients with schizophrenia are current smokers. Cigarette smoke increases the activity of CYP1A2, thus decreasing the blood concentrations of many drugs, including olanzapine and clozapine.

Citrome et al (n=380) reported that the olanzapine concentrations were significantly lower in smokers with schizophrenia than in non-smokers. Previous clinical studies with small numbers of patients with schizophrenia reported that smokers had an approximately fivefold lower dose-corrected steady-state plasma olanzapine concentration and a lower decrease in the Brief Psychiatric Rating Scale-total score than non-smokers. Meanwhile, although the relationship between the clozapine concentration and clinical outcome is controversial, it was also reported that smokers who were treated with clozapine suffered side effects (ie, auditory hallucinations, hallucinations, hypersalivation, drowsiness, clonic seizures, convulsions and unconsciousness) after smoking cessation.

Many studies about the effects of smoking on the disposition of olanzapine and clozapine have been undertaken, but no definitive agreement regarding the dose adjustment in clinical practice based on the patient’s smoking status has been reached. There are several reasons for the slow progress in making the smoking-associated dosage selection: (1) the sample sizes of the previous studies were small; (2) each study used different pharmacokinetic (PK) parameters (eg, plasma concentration, plasma concentration to dose (C/D) ratio, clearance (CL)), and the degree of the effect of smoking on the dispositions of olanzapine or clozapine was different between studies. Therefore, a meta-analysis has been needed to overcome the limitations of the previous studies and to determine the degree of the effects of smoking on the disposition of olanzapine and clozapine, in order to develop standards that can be used to adjust the doses of olanzapine and clozapine used in clinical practice based on the smoking status of the patient.

In this study, we performed a meta-analysis of the effects of smoking on the disposition of olanzapine and clozapine.

METHODS
Study selection
A preliminary search of the literature covering the period from 1946 to August 2012 was undertaken to identify publications related to the effects of smoking on the disposition of olanzapine and clozapine. Electronic databases, including MEDLINE, Scopus and the Cochrane Library, were initially searched using six terms, in which either ‘olanzapine’ or ‘clozapine’ was paired with ‘smoking’ or ‘cigarette’ or ‘tobacco’ or ‘smoke’. We excluded studies other than English publications, and studies not performed on human participants, after the search. The inclusion criteria were as follows: (1) published in a peer-reviewed journal; (2) contained the mean C/D ratios (ng/mL)/(mg/day) of olanzapine or clozapine, and their SD in smokers and non-smokers, respectively, and we requested data from the author(s) if either the mean C/D ratios or the SD was not described and (3) the data were from participants who had received olanzapine or clozapine for at least a week. In this study, smokers were defined as participants who were currently smoking. Additionally, we divided the selected publications into two groups, that is, olanzapine and clozapine study groups (figure 1).

The review and analysis were conducted using the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) Statement as a guide. Two researchers (YT and JS) independently searched the literature. Once all the papers had been assessed, any discrepancies in the answers were identified and discussed between the scorers to reach a consensus on the single best option. Any points of assessment on which the scorers could not reach an agreement were resolved by a third scorer (NY-F). The data were extracted from each article using a standardised form including the first author, publication year and other information, as described in the following section.

Data extraction
The number of patients, the mean values of the C/D ratios and the SD values of these ratios were extracted for smokers and non-smokers, respectively, from the selected publications. The C/D ratios were standardised to be in the same units, that is, (ng/mL)/(mg/day). When the values were not described or they were drawn on another scale (eg, (ng/mL)/(mg/kg)), we asked the author(s) to send us their data in the desired units. We tried to gather information by requesting it from 26 authors. Although five authors responded to our requests, the other 21 studies of olanzapine or clozapine could not be included due to a lack of information (the mean C/D ratios and SD were not available for smokers and non-smokers, respectively, from 14 studies, the SD was not given in four studies, and the mean C/D ratios were described on another scale, ie, (ng/ml)(mg/kg), in three studies; figure 1).

The characteristics of the studies included in this meta-analysis of the effects of smoking on the disposition of olanzapine or clozapine are shown in tables 1 and 2.
We systematically assessed several key points of study quality proposed by the MOOSE Collaboration.\textsuperscript{18} The quality of the included studies is shown in Table 3.

### Statistical analysis

A meta-analysis using the weighted mean difference in the C/D ratios of olanzapine or clozapine between smokers and non-smokers was performed using the Review Manager (RevMan) V.5.1 for Windows software program (Cochrane Collaboration, http://www.cc-ims.net/RevMan). Cochran’s $\chi^2$-based $Q$-statistic test was applied to assess the between-study heterogeneity. The weighted mean difference was calculated using the DerSimonian-Laird\textsuperscript{19} random effects models, along with

95% CI, to measure the strength of the association. In this study, we applied the random effects model for the comparisons, which is more conservative because of the possibility that the underlying effect differed across studies and populations. The weighted mean difference was also calculated when the studies were stratified according to the study design, that is, prospective or retrospective study. We used the I² statistic to assess the heterogeneity of the results. Publication bias was assessed by visually examining a funnel plot with asymmetry and formally assessing publication bias with the Egger et al's test. The statistical significance level for all analyses was set at a two-sided value of p<0.05.

RESULTS

Olanzapine: search results and study characteristics

Eight studies of olanzapine7 21–27 met our criteria (figure 1). The studies included in this analysis for olanzapine are listed in table 1. Since the study by Citrome et al7 was derived from a randomised clinical trial of 10, 20 and 40 mg as the daily olanzapine dose in patients with schizophrenia or schizoaffective disorder, we divided its populations into three groups according to the respective olanzapine doses. Since the study by Spina et al25 focused on the effects of valproate on the olanzapine plasma concentrations, we extracted the C/D ratios of olanzapine at baseline (before taking valproate). The study by Haslemo et al27 focused on the effects of contraceptives on the serum concentration of olanzapine among female patients who were treated either with olanzapine alone or the combination of estradiol-containing contraceptives, so we requested the C/D ratios in participants not using any contraceptives that can affect the CYP1A2 activity.

Primary analyses of olanzapine

The weighted mean difference was derived from all studies, comprising a total of 1134 patients (683 smokers and 451 non-smokers) with schizophrenia or other psychiatric disorders. The C/D ratio was significantly lower in smokers than in non-smokers (p<0.00001; figure 2),

NA, not available.
and the mean difference was $-0.83 \text{ (ng/mL)/(mg/day)}$ (95% CI $-1.04$ to $-0.63$). Although there was no significant publication bias ($p=0.26$), significant heterogeneity was observed ($I^2=50$, $p=0.04$). Since we included two studies by the same authors, we excluded the older study$^{21}$ in the subsequent analyses to reduce the heterogeneity.

The analysis from the seven studies showed that there was no significant heterogeneity among the mean differences ($I^2=11\%$, $p=0.35$; figure 3A). The weighted mean difference was derived from all studies, comprising 1094 patients (652 smokers and 442 non-smokers) with schizophrenia or other psychiatric disorders. The C/D ratio was significantly lower in smokers than in non-smokers ($p<0.00001$; figure 3A), and the mean difference was $-0.75 \text{ (ng/mL)/(mg/day)}$ (95% CI $-0.89$ to $-0.61$). No significant publication bias was shown using the Egger test in the studies of olanzapine ($p=0.282$). The funnel plot also suggested that publication bias was unlikely (see online supplementary figure S1).

**Subgroup analyses of olanzapine**

**Prospective studies**

We conducted subgroup analyses to confirm the precision of the primary analyses. Of the seven included studies of olanzapine, three were prospective studies, while four were retrospective studies. In the prospective studies (532 smokers and 272 non-smokers), the C/D ratio was significantly lower in smokers than in non-smokers ($p<0.00001$; figure 3B), and the mean difference was $-0.73 \text{ (ng/mL)/(mg/day)}$ (95% CI $-0.95$ to $-0.50$).

**Retrospective studies**

In the retrospective studies (120 smokers and 170 non-smokers), the C/D ratio was significantly lower in smokers than in non-smokers ($p<0.00001$; figure 3C), and the mean difference was $-0.84 \text{ (ng/mL)/(mg/day)}$ (95% CI $-1.08$ to $-0.59$).

**Clozapine: search results and study characteristics**

Four studies regarding the clozapine disposition$^{21}$ $^{28}$–$^{30}$ met our criteria, all of which were retrospective studies (figure 1). The clozapine studies included in this analysis are listed in table 2.

**Analyses of clozapine**

There was no significant heterogeneity among the mean differences ($I^2=33\%$, $p=0.22$; figure 4). The weighted mean difference was derived from all studies, comprising 196 patients (120 smokers and 76 non-smokers) with schizophrenia or other psychiatric disorders. The C/D ratio was significantly lower in smokers than in non-smokers ($p=0.00001$; figure 4), and the mean difference was $-1.11 \text{ (ng/mL)/(mg/day)}$ (95% CI $-1.53$ to $-0.70$). No significant bias was shown using the Egger test for the clozapine studies ($p=0.436$). The funnel plot also suggested that publication bias was unlikely (see supplementary supplementary figure S2).

**DISCUSSION**

Smoking is a well-known cause of significant drug interactions in humans.$^{31}$–$^{33}$ The polyaromatic hydrocarbons in cigarette smoke are known to induce CYP1A2,$^{34}$ and therefore cigarette smoking can affect the disposition of drugs that are metabolised by CYP1A2, such as olanzapine and clozapine. The prevalence of current smokers is higher in patients with schizophrenia than in the general population.$^5$ However, at present, there are no definitive data regarding the dose adjustments of olanzapine and clozapine in clinical practice based on the patient’s smoking status. This is the first meta-analysis to clarify the effects of smoking on the disposition of these drugs.

**Olanzapine**

In the meta-analysis of olanzapine, 1094 patients (652 smokers and 442 non-smokers) from seven clinical studies of olanzapine were evaluated. The results showed that the C/D ratio of olanzapine was $0.75 \text{ (ng/mL)/(mg/day)}$ lower in smokers than in non-smokers. The subgroup analyses (prospective/retrospective studies) also showed similar results. Approximately 85% of the oral olanzapine dose is absorbed, but as about 40% is

![Figure 2](http://bmjopen.bmj.com/)

---

inactivated by first-pass hepatic metabolism, its oral bioavailability is about 60%. The mean half-life, mean apparent drug plasma CL and mean apparent volume of distribution of olanzapine were 33 h, 26 L/h and 1150 L in healthy individuals. Previous clinical studies demonstrated that the C/D ratio of olanzapine correlated significantly with a decrease in the Brief Psychiatric Rating Scale. The association between the clinical outcome and the plasma olanzapine concentration is clearly curvilinear, with clinical efficacy being approximately associated with a plasma olanzapine concentration range of 20–50 ng/mL. Bigos et al. (n=523) analysed the population PKs of olanzapine, and they determined that sex, smoking and race contribute to the variability in olanzapine CL. The study also demonstrated that smoking increased the olanzapine CL by 55%, while also incorporating other confounding factors. Based on the findings of the present study, it was estimated that if 10

Figure 3  Forest plot (A) olanzapine study (n=7) (B) prospective olanzapine study (n=3) (C) retrospective olanzapine study (n=4).

Figure 4  Forest plot clozapine (n=4).
and 20 mg/day of olanzapine (the usual doses in Japan) would be administered to smokers, about 7 and 14 mg/day, respectively, should be administered to non-smokers in order to obtain the equivalent olanzapine concentrations. These findings imply that the daily doses of olanzapine should be reduced by 30% in non-smokers compared with smokers.

**Clozapine**

In the meta-analysis of clozapine, 196 patients (smokers 120, non-smokers 76) from four clinical studies were evaluated. The results showed that the C/D ratio of clozapine was 1.11 (ng/mL)/(mg/day) lower in smokers than in non-smokers. After oral administration of clozapine, the drug is absorbed rapidly. Only 27–50% of the dose reaches the systemic circulation unchanged, because of extensive first-pass metabolism. There is a wide interpatient variability in PK parameters of clozapine. The mean half-life of clozapine ranges from 9 to 17 h. The plasma CL of clozapine was reported to be between 9 and 53 L/h, and the volume of distribution of clozapine was between 2 and 7 L/kg. The steady-state plasma concentrations of clozapine are reached after 7–10 days of dosing. The relationship between clozapine concentration and clinical outcome is controversial. According to the study by Spina et al., a receiver operating characteristics analysis showed that a clozapine concentration cut-off value of 350 ng/mL distinguished responders and non-responders with a sensitivity of 72% and a specificity of 70%. On the other hand, it has been suggested that the clozapine concentration does not correlate with the decrease in the Brief Psychiatric Rating Scale.

A recent review summarised the previous studies regarding the relationships between the clozapine concentrations and clinical response, and suggested that clozapine levels above 250–400 ng/mL are associated with an increased chance of a clinical response. Moreover, clozapine doses exceeding 500–600 mg/day of clozapine could carry an increased risk of seizures. Because the smokers who were treated with clozapine were reported to suffer from serious central nervous side effects after smoking cessation, it is necessary to regulate the clozapine dosage carefully when smokers stop smoking or decrease the amount of smoking. Li et al. (2012) applied non-linear mixed-effect modelling to characterise the PKs of clozapine in Chinese patients. In the final model, sex and the smoking status were identified as significant covariates for the CL of clozapine and norclozapine, and smokers had a 1.45-fold higher CL of clozapine than non-smokers. Based on the findings of the present study, it was estimated that if 200 and 400 mg/day of clozapine (the usual doses in Japan) would be administered to smokers, about 100 and 200 mg/day, respectively, should be administered to non-smokers in order to obtain the equivalent clozapine concentrations. These findings imply that the daily doses of clozapine should be reduced by 50% in non-smokers compared with smokers.

**Other factors affecting the disposition of olanzapine and clozapine**

Many previous clinical studies have reported that sex, race, age, comedication and the genotype could affect the disposition of olanzapine and clozapine. Since oestrogen is known to inhibit the activity of CYP1A2, it is not surprising that the CL of olanzapine and clozapine was reported to be lower in women than in men. Comedications are also known to affect the disposition of olanzapine and clozapine. Several drugs, such as fluoxetine and fluvoxamine, were reported to increase the blood concentration of olanzapine and/or clozapine through the inhibition of CYP1A2, CYP2D6, CYP3A4 and/or UDP-glucuronontransferase 1A4. Additionally, carbamazepine, phenobarbital and trimipramine were reported to decrease the blood concentrations of olanzapine and/or clozapine through the induction of CYP1A2 or CYP3A4. Race is known to be associated with variability in the CYP1A2 activity. Bigos et al. reported that African-Americans cleared olanzapine faster than did other races (ie, Caucasians, Asians and Native Americans). Moreover, many genetic polymorphisms were reported to affect the disposition of olanzapine and clozapine. A recent review suggested that UGT1A4*3, CYP1A2 rs247297, FM03 K158-G308, FMO1*6, FMO1 rs7877 and CYP3A4 rs472660 polymorphisms all influence the olanzapine metabolism. Regarding clozapine, Lee et al. showed that CYP1A2 rs2069521 and rs2069522 polymorphisms were significantly associated with the C/D ratio of clozapine, and CYP2D6 rs1135840 was associated with the ratio of norclozapine and clozapine. Nevertheless, in the present study, there were insufficient data available to assess the effects of these factors on the disposition of olanzapine or clozapine. Moreover, the influence of smoking on the disposition of olanzapine and clozapine might be different among different patient populations (eg, the elderly, women, different diagnostic groups), but we could not conduct a meta-analysis for these populations.

**Strengths and limitations of the study**

The major strengths of this study are that it synthesised the previous studies with standardisation of the PK parameters to the C/D ratios, clarified the degree of the effect of smoking on the C/D ratios and provided standards that can be used to adjust the doses of olanzapine and clozapine in clinical practice based on the patient’s smoking status. On the other hand, there are several limitations to this meta-analysis. The major limitations of the present study are that we could not use another search engine, for example, EMBASE, due to lack of the access authority, and we could not include the literature published in other languages (not in English) or the data regarding other confounding factors, such as the age, weight, gender, alcohol consumption and how much the participant smoked. This meta-analysis standardised the PK parameters to C/D ratios (ng/mL)/(mg/day), and...
therefore only seven studies for olanzapine and four studies for clozapine could be included. In the present study, we excluded 10 reports (three for olanzapine and seven for clozapine) because the data were not from participants who had received olanzapine or clozapine for at least a week (figure 1). When the values were not described or they were given in another scale, we tried to gather information by requesting it from 26 authors, but only 5 responded to our requests. The other 9 studies of olanzapine and 12 studies of clozapine could not be included (regarding olanzapine, the mean C/D ratios of olanzapine and its SD were not available for smokers and non-smokers in seven studies; the SD was not given in two studies. Regarding clozapine, the mean C/D ratios of clozapine and its SD were not available for smokers and non-smokers in seven studies; the mean C/D ratios were provided in another scale, ie, (ng/mL) (mg/kg) in three studies and the SD was not given for two studies). Additionally, we excluded one study21 in the analyses of olanzapine in order to reduce the heterogeneity. These may have led to a selection bias. Furthermore, we included the three results from Citrome et al27 independently, and therefore the correlation of these results should be verified using a random intercept in the mixed effects meta-analysis. When the three results were included separately in the meta-analysis, the weighted differences were not significantly different among the analyses (see supplementary figure S3). However, we could not apply the random intercept in the mixed effects meta-analysis, because we used the RevMan software program, which lacks this function for the analysis. In previous studies, the sum concentrations of clozapine and its metabolite, norclozapine, and the norclozapine to clozapine ratio were also used as a clinical outcome and an index of metabolic activity, respectively.1 However, we could not use these parameters for the present meta-analysis, because we used only the clozapine C/D ratio in order to be able to include as many studies as possible and to develop simple standards that can be used in clinical practice.

The other limitation is that this meta-analysis simply divided participants into smokers and non-smokers, so the amount of smoking was not able to be taken into consideration. It has been suggested that the smoking-induced changes in hepatic CYP1A2 abundance are dependent on the daily cigarette consumption.51 Therefore, the differences in the amounts of smoking might have contributed to the variations in the influence of cigarette smoking on the disposition of olanzapine and clozapine among the studies included. Additionally, this meta-analysis could not confirm patient adherence. It was previously reported that up to 80% of patients with schizophrenia are at least partially non-adherent,52 and this might have affected the results. Although we included the studies that described that the participants had taken the drug for at least a week, we could not obtain any information regarding the adherence, because none of the studies clearly described this information. Finally, the use of comedations, which may affect the disposition of olanzapine or clozapine, could not be excluded. Six participants in the study by Laika et al24 were taking carbamazepine and 21 participants in the study by Weide et al21 were taking carbamazepine or fluvoxamine. These drugs are known to affect the activity of CYP1A2 and/or CYP3A4, which is also involved in the metabolism of olanzapine and clozapine.

CONCLUSION
This meta-analysis synthesised previous studies and represented the effects of smoking on the disposition of olanzapine and clozapine in a way that can be used to change the current clinical practices. Based on the results of this meta-analysis, we suggest that the doses of olanzapine and clozapine should be reduced by 30% and 50%, respectively, in non-smokers compared with smokers in order to obtain an equivalent olanzapine or clozapine concentration. These results are useful as standards to change the doses of olanzapine and clozapine in clinical practice based on the patient’s smoking status.

Acknowledgements The authors would like to acknowledge Kristi Bigos, Jeran Trangle, Tore Haslamo, Werner Steimer and Lionella Palego for providing them their data regarding the disposition of olanzapine or clozapine.

Contributors YT reviewed all the abstracts, reviewed all the full papers, performed the statistical analysis and wrote the paper. JS and NY-F reviewed all of the abstracts and full papers for relevance, and wrote and reviewed the submitted article.

Funding This work was supported by grants-in-aid (Nos. 23510348, 24500652 and 25860117) for scientific research from the Japanese Ministry of Education, Science, Sports and Culture.
