Low health literacy and cancer screening among Chinese Americans in California: a cross-sectional analysis

Tetine L Sentell,1 Janice Y Tsoh,2 Terry Davis,3 James Davis,4 Kathryn L Braun5

ABSTRACT

Objectives: Cancer is the leading cause of death among Asian Americans. Chinese Americans comprise the largest Asian American ethnic group. Low health literacy (LHL) is associated with lower cancer screening rates, but this association has not been studied in Chinese Americans. We examined the relationship between LHL and meeting US Preventive Service Task Force (USPSTF) guidelines for cervical, colorectal and breast cancer screening among Chinese Americans.

Setting: California, USA

Participants: Chinese respondents in age/gender groupings appropriate for USPSTF cancer screening guidelines (cervical: women ages 21–65, n=632; colorectal: men or women ages 50–75, n=488; and breast: women ages 50–74, n=326).

Outcomes: Relationships were tested using multivariable logistic regression models controlling for healthcare access and demographic factors, including limited English proficiency (LEP). The combined effects of having both LHL and LEP were specifically examined. LHL was measured by 2-items on perceived ease-of-use of written medical materials. All study variables were self-reported.

Results: Cancer screening percentages among Chinese Americans were 77.8% for cervical, 50.9% for colorectal (47.9% for women and 54.2% for men), and 85.5% for breast. LHL was associated with lower odds of meeting breast cancer screening guidelines (OR 0.41; 95% CI 0.20 to 0.82). Respondents with both LHL and LEP were significantly less likely to have up-to-date colorectal (OR 0.49; 95% CI 0.25 to 0.97) and breast cancer screening (OR 0.21; 95% CI 0.08 to 0.54) than those with neither health communication barrier. In all multivariable models, having seen a physician in the past year was a significant predictor of an up-to-date screening.

Conclusions: In Chinese Americans, LHL and LEP were negatively associated with up-to-date breast and colorectal cancer screening, independent of a recent physician visit. Efforts to promote cancer screening among Chinese Americans should consider and address LHL, LEP and physician access barriers.

INTRODUCTION

Cancer is the leading cause of death among Asian Americans.1 Chinese Americans comprise the largest Asian ethnic group in the USA2 and have particularly low cancer screening rates.3–4 For instance, Chinese American women are less likely than many Asian American and Pacific Islander women to report having a recent Pap smear or mammogram.3,4 Underuse of colon cancer screening is also seen among Chinese American men and women.5 Gaining a better understanding of the predictors of cancer screening among distinct Asian American populations, such as Chinese Americans, is important for targeted cancer control interventions.6,7

Health literacy, “the degree to which individuals have the capacity to obtain, process, and understand basic health information and...
services for appropriate health decisions, is an established correlate to cancer screening. Low health literacy is associated with limited knowledge about cancer screening, lack of desire for screening and poorer access to care. Limited research has focused on low health literacy in cancer screening among Chinese Americans specifically.

An additional issue to consider for cancer screening in Chinese Americans is limited English proficiency (LEP). Over half (58%) of Chinese Americans have LEP, a major health communication barrier. Previous studies have found that LEP is associated with lower rates of cancer screening generally and specifically in Chinese Americans. For instance, 57% of Chinese American women with LEP reported having a Pap test compared to 76% who were English proficient. A recent analysis of a population-based database in California found that Asian Americans with both LEP and low health literacy, or with LEP-only, were significantly less likely to be screened compared to those with neither limited literacy nor LEP.

This study had two primary aims. The first was to examine the relationship between low health literacy and meeting the US Preventive Service Task Force (USPSTF) guidelines for cervical, colorectal and breast cancer screening among Chinese Americans in California. These three cancers share four traits—they represent significant public health problems, have strong methods for early detection, have evidence that screening is useful, and show disparities among Asian American groups. The second aim was to quantify the combined burdens of low health literacy and limited English proficiency on meeting the guidelines. Evidence suggests that the combination of these two health communication barriers may indicate a particular vulnerability to not receiving recommended cancer screening.

METHODS
Sample
The 2007 California Health Interview Survey (CHIS) was used. The CHIS is a random-digit-dial (RDD) telephone survey administered by UCLA Center for Health Policy Research. It is representative of the non-institutionalised population of California, which is home to 4 out of every 10 Asian Americans in the USA. The 2007 CHIS multistage sample design included landline and cellular telephone numbers. For the landline RDD sample, the state was divided into 44 geographic sampling strata from which residential telephone numbers were selected. Within each household, one adult (18 years and over) respondent was randomly selected. The separate RDD cellular sample was drawn from telephone numbers assigned to cellular service and stratified by area code. The CHIS interviews in Mandarin and Cantonese, allowing for participation by Chinese individuals with limited English proficiency. CHIS English proficiency and cancer screening variables have been used extensively in other studies on this subject.

Outcomes
Breast cancer: In the 2007 CHIS, following National Health Interview Survey protocol, women 30 years and older were asked if they ever had a mammogram. Those who had received one were asked, “How long ago did you have your most recent mammogram?” USPSTF defines meeting breast cancer screening guidelines as having a mammogram in the past 1–2 years for women aged 50–74.

Cervical cancer: women 18+ who were not currently pregnant and had never had a hysterectomy were asked if they ever had a Pap smear. If yes, they were asked, “How long ago did you have your most recent Pap smear test?” Following USPSTF guidelines, meeting cervical cancer screening was defined as a Pap smear in the past 1–3 years for women aged 21–65.

Colorectal cancer: compliance with colorectal screening guidelines was obtained for all participants 50 years and older based on a series of cancer screening variables concerning fecal occult blood test (FOBT) in the past year, a flexible sigmoidoscopy or double-contrast barium enema in the past 5 years, or a colonoscopy in the past 10 years, per USPSTF guidelines. Respondents who reported a colorectal cancer (CRC) test were asked if they completed the test due to a problem. (Approximately 4–8%, depending on the specific CRC test, did so.) Meeting colorectal cancer screening guidelines was defined as ‘yes’ for the compliance guideline variable for men and women 50–75 excluding the 4–8% who took a CRC test due to a problem, as utilisation for diagnostic purposes may be subject to different factors than screening.

Low health literacy
Health literacy in the 2007 CHIS was assessed by two questions: (1) “When you get written information at a doctor’s office, would you say that it is very easy, somewhat easy, somewhat difficult, or very difficult to understand?” and (2) “When you read the instructions on a prescription bottle, would you say that it is very easy, somewhat easy, somewhat difficult, or very difficult to understand?” Respondents could report not getting written information (<4% of all respondents) or not using prescription medicine (<2% of all respondents). In the full sample, <1% of the sample lack a response to either question. Low health literacy was defined as responding that either one of these two tasks were ‘somewhat’ or ‘very difficult’ to understand. These items are similar to validated health literacy self-report measures that perform well in identifying low health literacy relative to standard instruments and these particular items have been used in a number of previous studies.

Limited English proficiency
Respondents who spoke any language(s) at home besides English were asked: “Since you speak a language other than English at home, we are interested in your own opinion of how well you speak English. Would you say you speak English very well, well, not well, or not at all?"
all?” LEP was defined as self-reporting speaking English ‘not well’ and ‘not at all.’ This LEP variable is considered a superior measure for language barriers in health,\textsuperscript{46} has strong face validity and is standard in many studies.\textsuperscript{41, 42}

**Low health literacy and LEP combined burdens**

Previous research has found that having both low health literacy and LEP together is associated with notably poor rates of colorectal cancer screening\textsuperscript{19} as well as other health disparities, such as poor health.\textsuperscript{38} Thus, a four-category variable was created using low health literacy and LEP combinations, coded 1=both LEP and low health literacy, 2=only LEP, 3=only low health literacy, and 4=neither LEP nor low health literacy.

**Covariates**

For multivariable models, control variables included: Age (continuous 18–75), sex (male or female, as relevant), education (less than high school, high school graduate, college graduate, more than college), poverty (≤100%, of poverty vs not), living in a rural area (vs not), current insurance (vs none), being born in the USA (vs elsewhere) and marital status (married vs other). These variables are associated with health literacy, limited English proficiency and/or cancer screening in other studies.\textsuperscript{43} As insurance coverage does not necessarily guarantee healthcare access, we also included the dichotomous item (yes=1 or no=0) for “Visited a doctor in the past 12 months?”\textsuperscript{44}

**Language concordance**

Based on previous research,\textsuperscript{44} we also examined the role of patient-provider language concordance in compliance with cancer screening guidelines specifically among those with LEP. The patient-provider language concordance variable had two groups: (1) other-language concordant (patients and providers spoke the same non-English language) or (2) language discordant (patient did not share a language with their provider).\textsuperscript{19, 45} For Chinese Americans with LEP, we first considered whether the language concordance variable had a significant relationship with each type of cancer screening in bivariate models. Then, for screening types in which a significant relationship was found for language concordance, language concordance was included in final multivariable models.

**Samples**

This study included three samples as different age groups and gender combinations are targeted by a distinct set of screening guidelines. Following the USPSTF guidelines,\textsuperscript{24–26} the cervical cancer sample included women ages 21–65, the breast cancer sample included women ages 50–74 and the colorectal cancer sample included men or women ages 50–75. All samples excluded individuals with missing health literacy measures and/or missing information regarding the screening outcome of interest. The unweighted sample sizes are as follows: cervical: 632; colorectal: 488; and breast: 326.

**Statistical methods**

The 2007 CHIS public-use data file was used for all analyses. All data were analysed in STATA V.10.\textsuperscript{46} using appropriate weighting methods to both correct for the complex sample design and to provide population-level estimates using the CHIS variables provided for this purpose in the public-use data file.\textsuperscript{47} Population-total weighting information was derived using data from the California Department of Finance’s 2007 Population Estimates and 2007 Population Projections across 11 demographic, geographic, household composition and socioeconomic factors.\textsuperscript{47}

We first report descriptive statistics and cancer screening by low health literacy, compared using $\chi^2$ analyses. We then ran multivariable logistic regression models predicting cancer screening for each sample by low health literacy with LEP including control variables (US nativity, age, sex, marital status, insurance, education, living in a rural area, poverty and recent doctor visit). All tests of statistical significance were two sided.

We then ran the same models including the four LEP and low health literacy combination groupings to examine and quantify the combined low health literacy and LEP burdens on cancer screening. Having neither low health literacy nor LEP was the reference group.

**RESULTS**

As seen in table 1, 85.5% met breast cancer screening guidelines, 77.8% met cervical screening guidelines, and 50.9% met colorectal screening guidelines (47.9% for women and 54.2% for men). Low health literacy was almost 30% or higher among all samples. LEP was above 40% in the breast cancer and CRC cancer screening samples, and almost 30% in the cervical cancer group. Many individuals had both LEP and low health literacy: 29% in the breast screening sample; 17% in the cervical sample, and 27% in the CRC sample. Of interest, 84% or more of each sample was born outside of the USA, 45–60% of each sample had a college degree (although perhaps from another country), 12–16% were living at or under 100% of the federal poverty level and about 8–15% were uninsured. Across all samples, a little more than 80% had visited a doctor in the past year.

As seen in table 2, in adjusted models including low health literacy and LEP separately, a recent physician’s visit was highly associated with up-to-date cancer screening in all three samples with an OR greater than 2 in all three models. Independent of a recent physician’s visit,

*Factors significant p<0.05.

HS, high school.
low health literacy was significantly (p<0.05) associated with lower odds of meeting breast cancer screening guidelines (OR 0.41; 95% CI 0.20 to 0.82), was marginally associated with meeting cervical cancer screening guidelines (OR 0.46; 95% CI 0.21 to 1.02; p=0.55), and was not significantly associated with meeting colorectal cancer screening guidelines (OR 0.70; 95% CI 0.38 to 1.30). No other variables were significantly associated with mammography or CRC screening in the multivariable models. Age (older) and marital status (married) predicted screening in the cervical cancer sample.

Data on compliance with screening guidelines by the four low health literacy-LEP combination groups are shown graphically in figure 1. For breast cancer, 69.2% of those with both LEP and low health literacy met screening guidelines, while the other three groups had over 88% screening rates (figure 1). For CRC screening, only 39% of those with both LEP and low health literacy met screening guidelines, compared to 61% of those with neither LEP nor low health literacy. However, for cervical cancer screening, the LEP and low health literacy group was not the group with the lowest per cent reaching screening guidelines. Instead, the group with lowest per cent reaching screening guidelines was those with low health literacy only.

Findings from the multivariable logistic models considering the four low health literacy-LEP combination groups (adjusted for control variables) for each screening type are provided in table 3. In adjusted models, following the patterns in figure 1, those with both LEP and low health literacy were significantly less likely to meet breast cancer screening guidelines (OR 0.21; 95% CI 0.08 to 0.54) and colorectal cancer screening (OR 0.49; 95% CI 0.25 to 0.97) than those with neither LEP nor low health literacy (table 3). Visiting a doctor in the past year was again highly predictive of screening in all three models.

Considering language concordance, in descriptive analyses among those with LEP (not shown in table), not having a language concordant provider was significantly associated with poorer screening for mammography specifically (61% with no concordant provider vs 86% with a concordant provider, p=0.01). Thus, language concordance was included in the multivariable models for mammography. However, this factor was not significant in multivariable models. Language concordance was not associated with Pap or CRC screening in descriptive analyses and was not included in multivariable models for those outcomes.

**DISCUSSION**

Our study shows that health literacy is an important factor to consider for understanding low cancer screening rates among Chinese Americans. Low health literacy alone was associated with lower odds of meeting breast cancer screening guidelines and those with both LEP and low health literacy appear to be at particularly high risk for not meeting colorectal and breast cancer screening guidelines. Even after considering having a recent visit with a physician, having low health literacy and limited English proficiency together was an independent predictor of screening for two out of three cancer screening types. Visiting a doctor in the past year was also highly predictive of all three types of cancer screening. This highlights the importance of healthcare system access above and beyond insurance coverage in ensuring receipt of needed preventive care. We also note that English proficiency and health literacy appear to have distinct relationships with the three types of cancer screening.

Our findings suggest that for breast cancer interventions in particular, strategies to improve health literacy (such as simplifying health information) or to increase...
the health-literate nature of the healthcare organisation (such as confirming understanding at all points of patient contact) may increase screening in Chinese Americans, particularly in concert with other proven strategies. It also suggests that including health literacy in multivariable studies of factors associated with Chinese American cancer screening may be important to understand all significant contributors to screening behaviour in this group.

We also find that Chinese Americans with the combined barriers of LEP and limited health literacy are a particularly vulnerable population for colorectal and breast cancer screening. This supports previously findings of linguistic barriers to care and low screening rates among Chinese Americans with LEP with further insight about the additional burden of low health literacy. Of relevance, in a previous study of LEP and low health literacy with CHIS data, Chinese reported the highest rates of both low health literacy and low health literacy with CHIS data, Chinese American cancer screening may be important to understand all significant contributors to screening behaviour in this group.

Those with both LEP and low health literacy may fall outside many existing pathways of health communication as both English or adapted Chinese language print materials may not be accessible. Promising research has found that multifaceted, culturally and linguistically appropriate interventions, including health educators in the primary care setting, can improve cancer screening in Chinese American populations. Such interventions may be critically important for those with LEP and low health literacy in order to illuminate access opportunities and to combat misconceptions about screening (such as whether women who are not sexually active should be screened).

Our findings also reveal the critical importance of regular access to a physician. Previous studies have shown that this access factor is associated with higher rates of preventive care and early detection of disease, but that regular visits to a doctor are less common among minority racial/ethnic groups, especially those with LEP. The powerful role of this variable in our study reveals the particular importance of this factor for Chinese Americans in general, and as a way to potentially overcome the impacts of health communication barriers of LEP and low health literacy specifically. This finding has critical current policy relevance in light of the expanded insurance coverage under the Affordable Care Act. Our study emphasises that insurance alone is only the first step to receiving needed preventing care; an actual connection with the healthcare system is also critical.

Our research found distinct relationships for low health literacy and LEP by screening type. This may be related to differential health literacy and health communication demands by screening type. The three cancer screening types vary in procedural complexity, direct patient involvement, and/or the number of contact or communication points needed to complete the screening. For cervical cancer screening with a Pap test, the procedure is often completed in a single medical visit with minimal preparation by the patient. Our results

*Factors significant p<0.05. LEP, limited English proficiency; LHL, low health literacy; HS, high school.
showed that visiting a doctor in the past year was particularly critical for receiving this procedure specifically and neither of our health communication variables was significant in the cervical cancer models when this factor was included. For mammography, the complexity of screening completion is higher, as it can require navigating (and potentially scheduling) a separate visit often at a different location than the doctor’s office. Our findings showed that low health literacy has an independent association with low mammography screening and that the combined burdens from both low health literacy and LEP exacerbate the barriers for obtaining mammography. CRC screening is the most complex of our tested screening procedures, involving multiple contact points and including previsit preparations (such as stool collection and handling for Fecal Occult Blood Test or Fecal Immunochemical Test or dietary preparations prior to colonoscopy). These screening procedures demand literacy skills to comprehend and implement instructions. Among Chinese Americans, CRC screening had the lowest adherence rate among the three cancers studied, and the combined burdens of low health literacy and LEP were associated with lower rates of up-to-date CRC screening in this population.

Both culturally and linguistically appropriate services are likely needed to reduce healthcare disparities. While having a recent doctor visit was highly predictive of receipt of cancer screening, health communication variables were also important. Healthcare systems and providers able to effectively address Chinese specific cultural concerns around cancer screening are needed, especially for those with limited understanding of the US medical system (for which LEP and/or low health literacy may be proxy measures).

This study has many strengths, such as a population-based data set with significant numbers of Chinese Americans, including those with LEP. However, some issues should be considered during interpretation. The health literacy items have been used in a number of previous studies and were taken from the Commonwealth Fund’s 2006 Quality of Care Survey, but they are self-reported and only focus on some aspects of health literacy. Also, to our knowledge, such self-reported health literacy items have been validated in English speakers but have not been validated in Chinese Americans specifically. It would be useful to consider differences in self-reporting health literacy challenges across Asian groups in the USA, due to known cultural differences in responses to questionnaires, including gender differences. It would also be useful to see how other health literacy domains, such as the ability not just to understand, but also to communicate, are described by Chinese Americans and how these might be impacted by LEP. Our CHIS data lack some variables, including cultural and health belief-related factors, associated with cancer screening in Chinese Americans. We also lacked the sample size to consider the independent role of factors that are highly associated with our included study variables (especially LEP and birthplace), but likely have distinct roles with cancer screening (such as Chinese language of preference, time in the USA, and other acculturation variables). Future study should consider the role of health literacy along with these variables.

Cancer screening among Chinese Americans also varies by geographic location. For instance, in Hawaii, Chinese Americans have higher cancer screening compliance than many other racial/ethnic groups, and higher rates of screening than are seen in these data from California. It would be helpful to see if the role of health literacy and/or LEP also varies, or if other factors are at play. These areas also have distinct patterns of immigration and differential percentages of Chinese relative to the larger population that may also be important in explaining these findings.

**Conclusions**

This study provides important new information about the role of low health literacy and limited English proficiency in cancer screening guideline adherence among Chinese Americans. Health literacy is increasingly recognised as an important factor in healthcare access and cancer screening in particular and is distinct from, but associated with, limited English proficiency. Efforts to promote screening in Chinese American communities should consider the health communication barriers of low health literacy and LEP separately and in combination to improve screening rates in these populations. Physician access barriers should also be considered as these appear critically important to cancer screening among Chinese Americans.

**Contributors** TLS conceived and designed the study, obtained the funding and drafted the manuscript. JYT helped to draft the manuscript, interpret analyses and contextualise study findings. TD participated in the study design and coordination and helped to draft the manuscript. JD participated in the design of the study, performed the statistical analysis and helped to draft the manuscript. KLB participated in the study design and coordination, and helped to draft the manuscript. All authors read and approved the final manuscript.

**Funding** This work was supported by the National Cancer Institute (1R03CA158419). Support for KLB was also provided by U54CA153459 from the National Cancer Institute. Support for JYT was supported by R01 CA138778 from the National Cancer Institute. Support for JD was also provided by U54MD007584 and G12MD007601 from the National Institute on Minority Health and Health Disparities. Support for TD was also provided by 1 U54 GM104940 from the National Institute of General Medical Sciences of the National Institutes of Health, which funds the Louisiana Clinical and Translational Science Center.

**Competing interests** None.

**Ethics approval** This study was deemed exempt by the University of Hawaii IRB.

**Provenance and peer review** Not commissioned; externally peer reviewed.
