Effectiveness of the management of major depressive episodes/disorder in adults with comorbid chronic physical diseases: a protocol for a systematic review and meta-analysis

Pablo Martínez,1,2,3,4 Ariel Castro,5 Diego Alonso,5 Paul A Vöhringer,1,3,6 Graciela Rojas1,3

ABSTRACT

Introduction Depression is a global-scale public health problem, and a significant association has been established between depression and chronic physical diseases. This growing comorbidity poses a challenge to healthcare systems. We aim to assess the effectiveness of the management of major depressive episodes/disorder in adults with comorbid chronic physical diseases.

Methods and analysis We will conduct a systematic review and meta-analysis of randomised clinical trials. Two databases MEDLINE and Cochrane Library (Cochrane Database for Systematic Reviews and CENTRAL), as well as the reference lists of the included articles, will be searched for studies either in English or Spanish with published results within the 2005–2015 period. Studies must fulfil the following conditions: (1) participants aged 18 years or older, diagnosed as having a major depressive episodes/disorder according to standardised criteria and chronic physical diseases; (2) interventions (be it pharmacological, psychological, psychosocial or a combination) must be compared with control conditions (other ‘active’ intervention, treatment as usual, waiting list or placebo); (3) and must report reduction in depressive symptoms after treatment, response to treatment, remission of major depressive episodes/disorder and significant improvement in quality of life. Data extraction, risk of bias evaluation, results summarisation and quality of the evidence (GRADE) will be performed as recommended by the Cochrane Collaboration. A qualitative synthesis and a random effects meta-analysis will be carried out. Effect sizes will be calculated (relative risk and Cohen’s d), I² and Q statistics will be employed to study heterogeneity and publication bias analysis will be performed. Subgroup analyses and meta-regression will be carried out.

INTRODUCTION

Depression is a global-scale public health problem due to its frequency, associated disabilities and recurrence. At the start of the present decade, it was estimated that the world prevalence of major depressive disorder had reached 4.4%, thus establishing itself as the main cause of years lived with disability (YLD), explaining 8.2% of the total YLDs in 2010.

The lack of timely treatment for unipolar depression is a predictor of poorer response, lower likelihood of remission, higher recurrence and greater risk of chronicity. This situation, in addition to inconsistencies in the management of the disease in real contexts and the insufficient resources assigned to mental health, amplifies the impact of depression as a public health problem.

In addition, a significant association has been established globally between depression and chronic diseases such as asthma, angina...
and diabetes, which illustrates the complex interaction between mental diseases—especially depression—and other health conditions, thus highlighting the notion that there can be no health without mental health and stressing the need to develop responsive health services.

It has also been documented that depression is a risk factor for chronic physical diseases and that it significantly worsens the health and the prognosis of its sufferers, which results in a greater usage rate of healthcare services and low treatment adherence; likewise, poor health and the presence of chronic diseases are risk factors for depression.

The strong link between depression and chronic physical diseases signals the presence of complex underlying biological mechanisms. Recent evidence strongly supports this notion: clear links have been observed between such pathologies, in the form of deregulations in the activity of the hypothalamic-pituitary-adrenal axis, a rise in metabolic stress, increased cellular ageing and an alteration of innate inflammatory response.

These shared biological pathways and lifestyle-associated factors may be the basis of morbimortality and disability in sufferers of these diseases, rather than the specific mechanisms of each health condition, which stresses the need to approach these problems in an integrated fashion. In this context, timely treatment for depression has been shown to have a major impact on the control of chronic diseases and on the reduction of healthcare costs.

The global health situation, characterised by a tendency towards ageing populations, along with a higher prevalence of chronic diseases and their increased degree of associated disability, poses a challenge to healthcare systems, which will also need to deal with a greater number of mental patients. In this context, the search for effective treatments for depression in people with comorbid chronic physical diseases gains relevance.

The most recent efforts made to summarise this evidence have been mainly limited by their use of studies that include subjects classed as depressed according to standardised criteria, which constitutes a potential source of heterogeneity, and by their focus on depression in specific chronic diseases or on a single type of therapeutic approach, such as psychoactive drugs. In view of the aforementioned, the present systematic review is intended to assess the effectiveness of the management of major depressive episodes/disorder in adults with comorbid chronic physical diseases.

**Objectives**

The objective of this systematic review is to assess the effectiveness of the available treatments for major depressive episodes/disorder in adults who suffer from chronic physical diseases. In order to do this, the present systematic review and meta-analysis seek to answer the following questions:

1. **Which treatments are effective in reducing depressive symptoms in adults with major depressive episodes/disorder and comorbid chronic physical diseases?**
2. **Which treatments for major depressive episodes/disorder in adults with comorbid chronic physical diseases are effective in achieving a response?**
3. **Which treatments are effective in achieving the remission of major depressive episodes/disorder in adults with comorbid chronic physical diseases?**
4. **Which treatments are effective in attaining a significant improvement in the quality of life of adults with major depressive episodes/disorder and comorbid chronic physical diseases?**

**METHODS AND ANALYSIS**

The Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols checklist was used for the publication of the protocol of the present systematic review and meta-analysis.

**Study eligibility criteria**

**Participants**

1. **Participant characteristics:** Adults, aged 18 years or older, with no distinction of sex or ethnicity, diagnosed with major depressive episodes/disorder and one (or more) comorbid chronic physical disease(s).

2. **Diagnosis of major depression:** The review will only include studies whose participants were diagnosed with major depressive episodes/disorder using the following standardised criteria: ICD-9 (International Classification of Diseases, 9th Revision), ICD-10 (International Classification of Diseases, 10th Revision), DSM-III (Diagnostic and Statistical Manual of Mental Disorders, 3rd Edition), DSM-IV or DSM-5. The diagnosis must have been provided by a qualified individual, either a psychiatrist or another suitably trained health professional.

3. **Comorbidities:** Comorbid physical diseases are not the main concern of this review; however, they must be diagnosed using well-established standardised criteria applied by qualified health professionals. Patients with one or more of the following conditions will be included: diabetes, cancer, cardiovascular diseases, chronic respiratory diseases, HIV infection, rheumatic diseases and gastrointestinal disease.

**Interventions**

1. **Pharmacological treatment:** Involving the use of tricyclic antidepressants (eg, amitriptyline), selective serotonin reuptake inhibitors (eg, fluoxetine), monoamine oxidase inhibitors (eg, phenelzine), serotonin and norepinephrine reuptake inhibitors (eg, venlafaxine), non-classified antidepressants (eg, buspirone) and/or any new antidepressant agents.

2. **Psychological therapy:** Any standardised treatment method with a well-defined psychotherapeutic content in which a collaborative bond is established between.
a patient and a provider (a psychologist or a suitably trained health professional), aimed at reducing the gravity of the symptoms of major depressive episodes/disorder and attaining a better level of functioning. Treatments can be intended for individuals, families or groups, in either a face-to-face or distance format, through the use of information and communication technologies. Examples of psychological therapies that may be included are: behavioural, cognitive, interpersonal, among others.

3. **Psychosocial interventions** Treatments intended to supply help, education or orientation to patients concerning major depression episode/disorder. These can include psychoeducational strategies, self-help groups, psychosocial rehabilitation strategies, support for reintegration to society or the workplace and monitoring, among others.54

4. Any combination of points 1, 2 and 3.

### Comparators

1. Comparison between one or more treatments labelled ‘interventions’ by the researchers and which are consistent with the previous section (Interventions).55

2. Treatment as usual/standard treatment for the management of the disease, established according to current norms or according to the criterion of the clinician at the relevant level of healthcare, conducted naturalistically.55

3. Waiting list in which patients are temporarily assigned to the treatment as usual/standard treatment condition until treatment and follow-up have been completed for those in the intervention group.55

4. Placebo: any control condition defined by the researchers as lacking an active component.55

### Outcomes

Studies must specify the following outcomes: reduction in depressive symptoms after treatment, response to treatment, remission of major depressive episodes/disorder and significant improvement in quality of life.

Further details are included in the Outcomes and prioritisation section.

### Study design

Randomised clinical trials, systematic reviews or meta-analyses published in the databases defined for the searches.

### Context

There is no restriction of setting; that is, patients can come from the primary, secondary or tertiary healthcare levels, from any healthcare system and from any country. The population included must be receiving treatment at a healthcare facility.

### Report eligibility criteria

Studies must have been published in English or Spanish. Publications must have an abstract available which includes its results. Study protocols will be excluded. Studies must have been published within the last 10 years, from 30 August 2005 to 30 August 2015.

### Information sources

The databases defined as information sources were MEDLINE and Cochrane Library (Cochrane Database for Systematic Reviews and CENTRAL). The search strategy for both sources is described in the relevant section.

In addition, the researchers reviewed the reference lists of the articles included in order to facilitate the identification of relevant studies.

### Search strategy

Table 1 includes the search strategies for each information source.

Study records
All the records yielded by the database search will be compiled and duplicates will be removed. Two authors (DA and PM) will review all the titles and abstracts independently and in duplicate to assess the eligibility of the publications. The results of this phase will be discussed within the group (AC, DA and PM), which will make it possible to estimate the degree of agreement reached. AC will provide his assistance to solve any disagreements that may arise.

Publications selected after reviewing their title and abstract, as well as those whose inclusion is in doubt, will be evaluated in full by three of the authors (AC, DA and PM). Disagreements will be solved through discussion and with the assistance of a fourth author (GR) whenever necessary.

Multiple publications of a single study will be grouped together to avoid repeating the same data. This is how the final list of studies included in the review will be defined.

To extract data from the studies selected and to present their characteristics, the format recommended in the Cochrane Handbook for Systematic Reviews of Interventions will be used.56

To follow this format, a piloting process will be conducted that will make it possible to estimate the degree of agreement reached. Three studies will be randomly selected and the authors (AC, DA and PM), independently and in duplicate, will extract information from them. The results obtained will be compared within the group, disagreements will be resolved through discussion and the consensual criteria for extracting information will be refined.

After this piloting process, the authors (AC, DA and PM) will divide the studies among themselves to extract data independently and will meet periodically to evaluate the fidelity of the process. The assistance provided by a fourth author (GR) will be used to solve substantial disagreements and to randomly evaluate the correspondence between the data reported by the studies and those extracted for the review.

Data items
Using the extraction format specified in the previous section,56 the data included will concern: the study (author, year), details about its design and the duration of the follow-up process, participant characteristics (setting, sex, age, type of chronic physical diseases (if specified), major depressive episodes/disorder, gravity of the symptoms (if specified) and any specific characteristics of the sample which are relevant to the clinical trial), intervention specifications (active and control groups) and the main results of the study that are relevant to the review.

Outcomes and prioritisation
Primary outcomes
1. Effectiveness in the reduction of depressive symptoms: Significant differences between the intervention and control groups in terms of depressive symptomatology after treatment, measured using validated questionnaires for depression: the Beck Depression Inventory,57 the Hamilton Depression Rating Scale,58 the Patient Health Questionnaire59 or the Montgomery-Åsberg Depression Scale,60 among others. Timing: not specified. At least two follow-up measures.

2. Treatment response: According to standard definition,61 a change of over 50% in depression scores on validated questionnaires, compared with baseline scores. Timing: not specified. At least two follow-up measures.

3. Remission of major depressive episodes/disorder: Absence of clinical depression after treatment completion, according to depression scores on validated questionnaires. Timing: not specified. At least two follow-up measures.

Secondary outcomes
1. Significant improvement in quality of life, evaluated through validated instruments, such as the SF-36 Health Survey62 or the WHO Quality of Life-BREF instrument.63 Timing: not specified. At least two follow-up measures.

Risk of bias: individual studies
Risk of bias will be assessed with the Cochrane Risk of Bias Tool, as per the Cochrane Handbook for Systematic Reviews of Interventions.56 This tool includes an assessment of six well-defined bias sources: random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data and selective reporting. Each of these sources is associated with specific criteria for classifying the risk of bias as high, low or unclear.

Usually, in randomised clinical trials of psychological interventions, it is not possible to blind the participants and providers.63 Even though this aspect will be considered and discussed as a plausible source of bias, it will not be prioritised in the evaluation compared with other potential sources of bias in studies of psychological interventions.

The same piloting process used for extracting data from the studies included will be carried out. AC, DA and PM will participate directly, while GR will supervise the process, providing her assistance to solve substantial disagreements and to randomly evaluate the fidelity of the data extracted vis-à-vis the original material.

No studies will be excluded from later analyses, regardless of the assessment of their risk of bias; however, this issue will be taken into account when discussing the effects of the studies on treatment effectiveness outcomes.

Data synthesis
In this stage, all the authors (AC, DA, GR, PM and PV) will work together.

A qualitative synthesis of all the studies included will be conducted in order to provide an overview of the
effectiveness of treatments for major depressive episodes/disorder in adults with chronic physical diseases.

A meta-analytic methodology will be applied, including a random effects model of the studies with relatively similar characteristics, since it is assumed that multiple sources of heterogeneity will exist (the studies are not identical).56

As effect size measures, in each of the selected studies, relative risk will be calculated for dichotomous outcomes, while the standardised mean difference (Cohen’s d) between treatment groups will be calculated for continuous data.66

In general, the treatments described in the intervention section will be compared with the control condition selected for each study in order to assess their effect on the primary and secondary outcome measures relevant to the present review.

Heterogeneity between randomised clinical trials will be studied by visually inspecting the resulting forest plots and by employing the $I^2$ and $Q$ statistics.67

Results will be summarised using the Summary of Findings table recommended in the Cochrane Handbook for Systematic Reviews of Interventions.56 This table will include:

A. Reduction in depressive symptoms achieved by the treatments, reported as a continuous outcome measure.
B. Response to treatments for major depressive episodes/disorder, reported as a dichotomous outcome measure.
C. Remission of major depressive episodes/disorder achieved by the treatments, reported as a dichotomous outcome measure.
D. Significant improvement in the quality of life of adults with major depressive episodes/disorder and chronic physical diseases achieved by the treatments, reported as a continuous outcome measure.

Subgroup analyses will be conducted by ethnicity, setting, type of physical chronic condition, psychiatric comorbidities and treatment type.

In addition, a meta-regression will be carried out. In order to do this, the sample will be stratified according to the initial severity of the major depressive episodes/disorder, which will make it possible to assess the potential differential effect of a treatment in connection with the severity of the disorder.

Meta-bias (ES)
Funnel plots and Egger’s test will be used to assess potential publication biases.68

Confidence in cumulative evidence
After presenting this summary of findings, the quality of the whole set of tests for each individual result will be assessed using the GRADE approach, as recommended in the Cochrane Handbook for Systematic Reviews of Interventions.56 This approach considers the following aspects: within-study risk of bias, directness of evidence, heterogeneity, precision of effect estimates and risk of publication bias. This approach specifies four levels of quality (high, moderate, low and very low).

Contributors
GR is in charge of the review, of supervising the process and of providing her expert opinion on the subject. DA, AC and PM made contributions to the development of the selection criteria and the search strategy and will be tasked with extracting the data and evaluating the risk of bias. PV provided his statistical and clinical expertise and will help to supervise the process. All the authors contributed equally to the study design and edited, modified and approved the final version of the manuscript.

Funding
This systematic review was financed by the Chilean National Fund for Scientific and Technological Development (FONDECYT), project no 1130230; the Fund for Innovation and Competitiveness (FIC) of the Chilean Ministry of Economy, Development, and Tourism, through the Millennium Scientific Initiative, grant no IS130005 and the Program for Institutional Improvement – Universidad de Santiago de Chile (PMI USA 1204) of the Ministry of Education, through the Information Technology Innovation Centre for Social Applications (CITIAPS). Financial backers are not involved in any other aspect of the project.

Competing interests
None declared.

Provenance and peer review
Not commissioned; externally peer reviewed.

Data sharing statement
No additional data are available.
