

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

Abstract

Objectives: To identify and appraise the methodological rigor of multivariable prognostic models predicting in-hospital paediatric mortality in low- and middle-income countries (LMIC).

Design: Systematic review of peer-reviewed journals.

Data sources: MEDLINE, CINAHL, Google Scholar, and Web of Science electronic databases since inception to August 2019.

Eligibility criteria: We included model development studies predicting in-hospital paediatric mortality in LMIC.

Data extraction and synthesis: This systematic review followed the CHARMS (Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies) framework. The risk of bias assessment was conducted using PROBAST (Prediction model Risk of Bias Assessment Tool). No quantitative summary was conducted due to substantial heterogeneity that was observed after conducting a meta-analysis of the studies included.

Results: Our search strategy identified a total of 4054 unique articles. Among these, 3545 articles were excluded after review of titles and abstracts as they covered non-relevant topics. Full texts of 509 articles were screened for eligibility, of which 15 studies reporting 21 models met the eligibility criteria. Based on the PROBAST tool, risk of bias was assessed in four domains; participant, predictors, outcome, and analyses. The domain of statistical analyses (events per variable, missing data, etc) was the main area of concern where 20/21 models were judged to be of high risk and one model judged to be of unclear risk of bias among the included models.

Conclusion: This review identified 21 models predicting in-hospital paediatric mortality in LMIC. However, most reports characterising these models are of poor quality when judged against recent reporting standards and have a high risk of bias. Future studies should adhere to standardized methodological criteria and progress from identifying new risk scores to validating or adapting existing scores.

Trial registration number: CRD42018088599

Article summary

Strengths and limitations of this study

- This is the first systematic review on methodological quality of prognostic models predicting in-hospital paediatric mortality in resource-limited settings.
- The review was based on robust search strategy with no language restriction yielding a large number of potentially eligible studies, hence it is unlikely that any potentially eligible study was not included.
- Quality of the included models was assessed based on recent reporting standards which we applied to the identified studies and we also highlighted limitations in the existing prognostic models.
- We relied on what was reported to determine the risk of bias of the models. For instance, if no mention was made of internal validation or even verification of the model assumptions, we assumed they were not done as required in prognostic model development.

Introduction

Over recent decades, there has been considerable progress in improving child survival¹ but child mortality remains high in sub-Saharan Africa relative to the rest of the world.² Paediatric deaths in hospitalized children mostly occur soon after admission,³ and are caused by common conditions such as malaria, pneumonia, and diarrhoeal diseases among others, which are readily treatable by cost-effective interventions.³⁻⁵ In low- and middle-income countries (LMIC), clinicians often use a set of clinical signs as recommended in the guidelines by World Health Organization (WHO) to identify patients at risk of deterioration while making decisions on appropriate treatment.⁶ Clinical criteria recommended by WHO were developed following expert recommendations based on review of evidence from studies reporting risk factors for mortality. Prognostic models, which use statistical equations to predict patients' risk based on the combination of prognostic factors, may improve clinicians' ability to identify high-risk patients and thus improve outcomes.⁷

Various clinical prediction models for hospitalised paediatric patients have been developed over the last 3 decades,⁸ however, there are doubts whether appropriate methodology has been used in their development.⁹ Notably, none are currently recommended for use in existing paediatric clinical practice guidelines in LMIC and systematic reviews of the methodology used in their development have been strongly recommended.¹⁰ This systematic review addresses this need and aims at identifying and summarizing existing studies reporting prognostic models for predicting in-hospital paediatric mortality in LMIC. Specifically, the research summarises the evidence from the published studies and appraises the methodological rigor of each existing model.

Methods

Protocol and registration

We registered the protocol for this review at PROSPERO (International Prospective Register of Systematic Reviews) (CRD42018088599).¹¹ This work is reported as per guidelines by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses).¹²

Eligibility criteria

Reports were eligible for inclusion if they met the following criteria:

1. Study design: peer-reviewed studies whose design was either a randomized controlled trial, cohort (prospective or retrospective), cross-sectional, or case-control observational study.
2. Outcome: studies fitting models predicting all-cause in-hospital mortality in a general paediatric ward were included. Studies predicting post-discharge mortality, trauma or operative mortality were excluded.
3. Target population and setting: studies on children aged over 1-month old admitted in general paediatric wards within LMIC as defined by the World Bank¹³ were included. Studies whose predictive models were targeting patients in intensive care unit (ICU) or high dependency unit (HDU) were excluded because these facilities are largely unavailable in low-resource settings. We also excluded studies whose predictive models targeted uncommon conditions in children e.g., chronic kidney disease, cancer, diabetes. However, if a study focused on one of the common childhood illnesses such as malaria, pneumonia, meningitis, anaemia, and diarrhoea/dehydration³ was included.

4. Type of studies: we included studies whose main objective was deriving a predictive model(s) or scoring system(s). We excluded commentaries, editorials, expert views, conference proceedings, case reports, case-series, reviews and explanatory studies that mainly generate hypothesis¹⁴.
5. Models: studies that reported multivariable model with at least 2 variables/predictors were included.
6. Full text and language: We excluded studies that were not available in full text. Non-English language studies were translated using Google Translate. Hence no language restriction was made.

Search strategy

As recommended by CHARMS checklist, we came up with seven key items (supplementary file 1 (Table 1)) applicable to our study that guided the framing of the search strategy, review aim and eligibility criteria.

We used Medical Subject Headlines (MeSH) terms where appropriate keywords to identify articles with prognostic models relevant for this review. A search of articles was conducted in MEDLINE, Google Scholar, and CINAHL (via EbscoHost) since inception to August 2019. We also performed a search in Web of Science to identify additional reports that cited the identified studies. Reference lists of all identified articles were searched manually to identify other potentially eligible studies.

We manually searched reference lists of all relevant articles to identify additional eligible studies. Final search results were collated in EndNoteX7™. Detailed search terms and strategy are provided in supplementary file 1 (Table 3).

Screening of articles

Prior to screening titles and abstracts, 2 reviewers (MO and LM) standardized the approach to be used in the process of screening. We used a sample of 30 search results to train and familiarize reviewers with the screening process. Titles and abstracts of the studies were screened by the two reviewers. Discrepancies were resolved via discussion and, when necessary, a final decision was adjudicated by a third reviewer (JA).

Data Extraction

Data were extracted from relevant articles in accordance with the Cochrane Prognosis Methods' guidance; the CHECKlist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies (CHARMS).¹⁵ From each study included, data were extracted on participant enrolment, study design, study population characteristics, location, sample size, number and selection of predictors, study dates, handling of continuous predictors, missing data, method of modelling (e.g., logistic regression, survival), verification of model assumptions, internal validation methods (e.g., random split of data, and resampling techniques); model presentation (e.g., nomogram, score chart, or regression formula with coefficients); and model performance metrics including discrimination -area under the receiver operating characteristic curve (AUC) with 95% confidence interval (CI); calibration; classification measures such as sensitivity, specificity, positive, and negative predictive values. We further investigated from literature to determine if included models have been externally validated elsewhere. For articles that described development of multiple prognostic models, we treated each model separately whenever the predictor-outcome association produced different model estimates. For each study, extracted data elements were compared between two reviewers (MO & LM), and any disagreements were resolved by discussion with the third reviewer (JA).

1
2
3 No quantitative summary was conducted due to substantial heterogeneity that was observed after
4 conducting a meta-analysis of the studies included.
5

6 7 ***Assessment of methodological quality*** 8

9
10 The *risk of bias* (shortcomings in the predictive models that might lead to unreliable
11 predictions)¹⁵ of the included studies was assessed based on the Prediction study Risk Of Bias
12 Assessment Tool (PROBAST).^{16 17} We assessed the *risk of bias* (RoB) for each model, in four
13 domains: participant selection (e.g. study design), predictors (e.g. assessment of candidate and
14 final model predictors), outcome, and analysis (e.g. handling of missing data, the handling of
15 continuous predictors) see supplementary file 1 (Table 2). For each domain, signalling questions
16 have five possible answers: yes; probably yes; probably no; no; and no information. Any positive
17 answer (yes, or probably yes) suggests low RoB. Each domain had three possible outcomes: low;
18 high; or unclear RoB. Using these domain outcomes, we came up with an overall judgement of
19 RoB for each model. As recommended by PROBAST, if a prediction model was judged as low
20 on all five domains, we assigned it an overall judgment of “low RoB”. If a model was rated as
21 high at least in one domain, we judged it as having “high RoB”. If at least one domain of the
22 model was rated as unclear and the rest of the domains rated as low, it was judged as having
23 “unclear RoB”. If a predictive model was rated as low RoB for all domains, and it has not been
24 subjected to any external validation, we downgraded it to “high RoB”.

Results

Characteristics of the included studies

Our search strategy identified a total of 4054 unique articles, 3545 articles were excluded after review of titles and abstracts as they reported non-relevant topics. Full texts of 509 articles were screened for eligibility, of which 15 primary studies reporting 21 developed models met the eligibility criteria (Figure 1). The eligible studies analysed data for patients who were below 15 years of age with median mortality being 6.7% (range 1.2% to 43.9%).^{18 19} While majority of the models were developed for general cases in paediatric wards (n=9), some were tailored for specific paediatric groups defined by common diagnoses such as febrile illness (n=1),²⁰ malaria (n=2),^{21 22} pneumonia (n=4),^{18 23-25} malnutrition (n=2)^{26 27} and other infectious diseases (n=3) (see supplementary file 1).

Most of the included studies have been published post year 2000 (n = 20) except for one study²⁶ published in 1996. The latest data used in the models under review were from 2016 to 2017 by Rosman *et al.*²⁸ and the oldest data were utilized by Drimax *et al.*²⁶ from 1986 to 1988.

Five reports of the 15 included studies utilized data from at least two centres of which 3 studies²¹ were conducted in multiple countries including sub-Saharan Africa and Asian countries (Figure 2). Of the reviewed studies, most of the information we were abstracting were either not reported or were partially reported, an indication of non-adherence to the TRIPOD (Transparent Reporting of a Multivariable Prognostic Model for Individual Prognosis or Diagnosis) guidelines.^{21 22 29 30}

Summary of issues in methodology of the reviewed models

Candidate predictors

There were 61 distinct predictors used in the final reported models (a median of 7 predictors in any one model). Initial selection of the candidate predictors was mostly based on univariable analysis except for three studies²⁶ where the selection was based on literature reviews or clinical relevance. Backward stepwise selection method was used in 6 models in a multivariable analysis to determine final model predictors. Commonly included predictors in the final models were: altered consciousness, malnutrition indicators, vital signs, and signs of respiratory distress (see Figure 3). Some models included predictors that were either not easy to obtain or required laboratory techniques.²⁶ Of the 13 models including continuous predictors, 8 models categorized continuous predictors where a continuous scale would have been possible. Two out of 13 models applied other techniques such as fractional polynomial^{29 31 32} and restricted cubic splines²⁷ to determine the suitable functional form of the continuous predictors (See supplementary file 2).

Sample size, events per variable (EPV) and missing data

Sample size ranged from 168²⁸ to 50,249³³ with a median of 1307. The median EPV was 21 (IQR 8.3 – 32.5) of which 7 models had less than 10 EPVs, suggestive of insufficient sample sizes which is prone to over-fitting. For instance, 60 deaths were reported in the dataset used to develop PEDIA-Immediate score in the study by Berkley *et al.*³⁴ In reference to the rule that a study developing predictive model should have a minimum of 10 events for each independent predictor in a prognostic model,³⁵ a model with, at the most, 6 predictors should have been considered but 10 predictors were considered instead hence making EPV 6.

1
2
3 Proportions of missing data was not always reported. Handling of missing data varied across the
4
5 reviewed studies as follows: 6 models did not report handling of missing data; 8 used complete
6
7 case analysis; 4 used multiple imputation (using Chained Equations); and one study²⁷ used single
8
9 imputation.
10
11

12 13 Model development

14
15 Majority of the studies applied logistic regression, one study³¹ used Cox regression, one study³⁴
16
17 used Spiegelhalter/Knill-Jones method and another study²² used a machine learning technique
18
19 (classification and regression trees (CRT)) in model development. Verification of model
20
21 assumptions was not reported in most of the studies. For instance, George *et al*³¹ despite utilizing
22
23 Cox regression to develop their model, did not report the verification of proportional hazard
24
25 assumption nor explore the possibility of competing risks. Other regression assumptions e.g.
26
27 multicollinearity was equally not reported. However, since backward elimination method
28
29 disregards redundant variables, we inferred the satisfaction of multicollinearity assumption if this
30
31 method was applied.³⁶ Five studies developed models using data from different countries/centres
32
33 but none of them clustered their analysis by source of data in a multilevel model to account for
34
35 heterogeneity. Ignoring clustering leads to a biased predictor effect.³⁷
36
37
38
39
40

41 Model performance evaluation & presentation

42
43 Performance measures (both calibration and discrimination) were poorly reported in most of the
44
45 studies and in most cases AUC for discrimination was reported (n=20). Performance of the
46
47 derived models was evaluated in 12 models using either split-sample, resampling methods, or
48
49 separate datasets. Except for the model derived by George *et al*,²⁰ all other models did not report
50
51 both apparent discrimination (without any adjustment for optimism) and optimism-corrected
52
53 discrimination measures. Despite inadequate reporting of the models' performance, 16 models
54
55
56
57

1
2
3 reported AUCs ≥ 0.80 , an indication of promising models. Apart from the following exceptions;
4
5 *Lambarene Organ Dysfunction (LOD) score*,²¹ *Paediatric Early Death Index for Africa (PEDIA)*
6
7 *score*,¹⁹ *Signs of Inflammation in Children that Kill (SICK) score*,³⁸ *Respiratory Index of Severity*
8
9 *in Children (RISC) score*,¹⁸ and *Modified Respiratory Index of Severity in Children (mRISC)*
10
11 *score*,³⁸ other scores have not been externally validated (by independent investigators using
12
13 diverse populations). Only 2 studies²⁴ developing 4 models provided a full model formula (both
14
15 coefficients and intercept/baseline function) in their results as recommended.^{39 40} While most of
16
17 the models (n=17) were presented as simplified integer scores, only a few were assigned weights
18
19 according to the regression coefficients.
20
21
22

23 24 **Risk of bias (RoB) assessment**

25
26
27 Based on the PROBAST tool, RoB was assessed in four domains; participants, predictors,
28
29 outcome, and analyses. Figure 4 summarizes the RoB assessment across all models included in
30
31 this review, the domain of outcome was deemed to be of low risk in all models. The domain of
32
33 statistical analyses was the main area of concern where 20/21 models were judged to be of high
34
35 risk and one model judged to be of unclear RoB (see Figure 5). Full details are provided in
36
37 supplementary file 3. Most of the models were downgraded to high RoB because of either
38
39 inadequate sample size (EPV <10) (n=7/21), poor handling of missing data (n=17/21), or using
40
41 discouraged techniques to perform model selection such as univariable analysis (n=18/21), a sub-
42
43 optimal approach in analysing continuous predictors (n=8), and lack of reporting on verification
44
45 of model assumptions (n=13). Details on each PROBAST criterion (20 signalling questions)
46
47 across domains are provided in the supplementary file 3.

Discussion

Summary of key findings

We conducted a systematic review to identify published scores predicting in-hospital mortality for paediatrics in resource-limited countries. Fifteen studies that described the development of 21 prognostic models were identified. We described characteristics of these studies as well as the methodological quality of the included models by using agreed recent guidelines applicable to predictive models. We have identified several important quality deficiencies such as inadequate reporting and other methodological concerns, including poor handling of missing data, automated selection of predictors, categorization of continuous predictors, inadequate EPV and the poor presentation of the proposed model for use. As a result, a majority (21 out of 22) of the included models were found to be of poor methodological quality and consequently judged to potentially high risk of bias in predictions (Figure 5).

Our findings suggest that predictive models fail to meet recently agreed methodological criteria in various ways. Firstly, in this review we observed that univariable analysis was routinely used in 18 out of 21 models in the selection of candidate predictors to be used in a multivariable analysis. This strategy tends to leave out possibly important prognostic factors which might be insignificant in a univariable analysis but turn out to be significant when combined with other predictors.^{39 40} *A priori* selection of predictors using expert opinion, clinical intuition or literature is recommended for this purpose,^{41 42} however only two models in this review employed this approach.^{39 40}

Small sample sizes in model development can lead to poor predictive performance, over-fitting, and biased effect estimates. Prognostic models must have a minimum of 10 events per candidate predictor, as this is the accepted norm⁴³⁻⁴⁵ and underpowered models arising from inadequate

1
2
3 events per variable (EPV) increase the possibility of spurious results.³⁵ In this review, 7 of 21
4
5 models had inadequate sample sizes (EPV<10) and there was no information on whether
6
7 bootstrapping, which serves to reduce overfitting was used in these models.⁴⁶
8
9

10 Just like most of the epidemiological studies, missing data is a common problem which is solved
11
12 using multiple imputation or other reasonable approaches, but this was rarely the case in the
13
14 model development studies under this review. For instance, 8/21 models used complete case
15
16 analysis (CCA), 4/21 used multiple imputation, and 6/21 models did not report how missing data
17
18 were handled and therefore we assumed CCA was used. Following Harrell's guidelines,⁴⁷ CCA
19
20 should only be used if the percentage of missingness is < 5% but the appropriateness of the CCA
21
22 approach could not be ascertained as most of the included studies failed to report the proportion
23
24 of missing data per variable. Inappropriate use of CCA results in use of only a small subset of
25
26 the data which cannot be regarded as a random sample from the target population unless data are
27
28 missing completely at random (MCAR),⁴⁸ a mechanism which is rarely in practice.¹⁵
29
30

31
32 Consequently, there are concerns about possible loss of precision in inferences and the potential
33
34 biases of the estimated parameters⁴⁹ in the models employing CCA. Finally, handling of
35
36 continuous predictors was a concern in this review. Of the 13 models including continuous
37
38 predictors, 8 models categorized continuous predictors where a continuous scale would have
39
40 been possible. While this approach is intuitive to most researchers, its simplicity comes at a
41
42 considerable cost of predictive performance.⁵⁰ The resulting prognostic models have been shown
43
44 to have poor predictive accuracy because of the loss of statistical power and information. It is
45
46 recommended that the nature of continuous data should be retained or handled by using other
47
48 techniques such as regression splines or LOESS functions.^{50 51} In this review, appropriate
49
50

4
5 polynomial^{29 31 32} and restricted cubic splines.²⁷
6
7

8 **Comparison with Other Studies**

9

10
11 Methods used to assess quality measures of the included models in the current study have been
12
13 applied previously to critically evaluate the quality of predictive models in other specialties.⁵²⁻⁵⁴
14
15 Just like the findings of this review, other previous reviews^{9 55-57} describing the development of
16
17 prognostic models highlighted a lot of flaws including inappropriate statistical analyses, poor
18
19 reporting of important clinical and methodological information needed for validation of the
20
21 model, and lack of external validations. Incomplete reporting of clinical models stops future
22
23 studies on prognostic research from building on the information of already existing models. This
24
25 has been marked as an important source of wasted research efforts.⁵⁸ For example, external
26
27 validation of prognostic models requires a full model formula to enable direct estimation of
28
29 survival probabilities.³⁹ However, this was presented in only 4 models. Thus, this review
30
31 highlights the need for researchers to adhere to the TRIPOD statement while developing
32
33 prognostic models. Of note, the quality of clinical predictive models does not appear to have
34
35 improved over time as previous reviews from 1996,⁵⁹ 1997,⁶⁰ 2001,⁶¹ 2005,⁶² 2011,⁸ 2012,⁶³
36
37 2016,^{64 65} 2017,⁶⁶ to 2019⁶⁷ have consistently identified suboptimal methodologies in these
38
39 predictive models. Poorly derived models may result in overoptimistic results and misleading
40
41 performance. Presumably there are reasons why many prognostic models are of poor quality,
42
43 including pressure to publish new predictive model regardless of the clinical value of the
44
45 resultant model.⁶⁸

55
56
57

Implications of this study

Most of the included models have not been externally validated despite repeated recommendations that this is needed.^{39 40 69-72} This suggests that researchers focus more on deriving new models, often using similar prognostic factors, rather than validating and improving existing in-hospital mortality prediction models. This leaves healthcare policy makers with doubts as to which model to recommend in their setting. Large datasets such as that of the Clinical Information Network (CIN)^{3 73 74} now exist in resource-limited settings. Future studies on prognostic research should leverage such datasets to externally validate competing models identified in this review for comparative performances as recommended by Collins *et al*,⁷⁵ and if necessary, predictive performance of such models should be improved by addition of new prognostic factors. Even so, the application of these models is likely to be impaired as most of the models reported have simplified the original predictor coefficients. This has an implication on model performance during external validation due to loss in predictive accuracy arising from rounding coefficients to nearest integers.¹⁵

Strengths and limitations

To our knowledge, this is the first review identifying models predicting in-hospital paediatric mortality in resource-limited settings. Our robust search strategy yielded a large number of potentially eligible studies, hence it is unlikely that any potentially eligible study was not included. The quality of the included models was assessed based on recent reporting standards and applied to the identified studies. For instance, if no mention was made of internal validation or even verification of the model assumptions, it could not be determined whether these crucial steps of model development were carried out or not. Thus, models that could have been

1
2
3 otherwise rated as low risk of bias were rated as either unclear or high risk of bias. Despite this,
4
5 we still hold that complete reporting of any proposed model is necessary to facilitate external
6
7 validation and its subsequent application in practice.
8
9

10 **Conclusion**

11
12 Rigorously developed and robustly validated promising predictive models have the potential for
13
14 improving child survival in resource-limited countries. This review identified models predicting
15
16 in-hospital mortality for paediatrics. However, most are of poor quality and have high risk of
17
18 bias. Our research highlights the need to improve on the identified quality deficiencies when
19
20 developing prognostic models in the future by adhering to existing generally accepted
21
22 standardized methodological criteria. Majority of the derived models have not been externally
23
24 validated as required. Inadequate reporting observed in the included models hinders rigorous
25
26 external validation by other researchers, leave alone implementing them in practice. Rather than
27
28 developing new prognostic models, researchers should carry out comprehensive joint external
29
30 validation of the identified models using large datasets ideally collected over extended time
31
32 periods and different locations. This will allow head-to-head comparisons and adaptation of the
33
34 competing models, if necessary, to ascertain their generalizability.

Funding

Funds from The Wellcome Trust (#207522) awarded to ME as a Senior Fellowship together with additional funds from a Wellcome Trust core grant awarded to the KEMRI-Wellcome Trust Research Programme (#092654) supported this work. The funders had no role in drafting or submitting this manuscript.

Author Statement

The roles of the contributors were as follows: ME, SA, and AA conceptualized the study. MO, LM and JA conducted electronic searches to identify eligible models and did analyses. MO drafted the initial manuscript with SA, NO, RS, AA, and ME contributed to its development. All authors read and approved the final manuscript.

Competing interests

The authors declare no conflicts of interest.

Data sharing statement

No additional data are available.

Lowlaavar 2016 (Model 2)	+	X	+	?	X
Lowlaavar 2016 (Model 3)	+	+	+	?	?
Mpimbaza 2015	X	+	+	X	X
Olson 2013(ITAT score)	X	+	+	X	X
Rosman 2019(PEWS-RL score)	X	+	+	X	X

Domains:
D1: Bias due to participants selection
D2: Bias due to predictors measurements.
D3: Bias due to determination of outcome.
D4: Bias due to analysis.

Judgement
● High
? Unclear
+ Low

Figure 5: Risk of bias assessment. Low means low risk of bias, High means high risk of bias, and Unclear when it was not possible to assess the risk of bias.

Key: PEWS-RL score=Paediatric Early Warning Score for Resource-Limited Settings; SICK score=Signs of Inflammation in Children that Kill; PET score= Paediatric Emergency Triage; mRISC score= Modified Respiratory Index of Severity in Children score; RISC score= Respiratory Index of Severity in Children score; PERCH severity score= Pneumonia Etiology Research for Child Health severity score; LOD score= Lambarene Organ Dysfunction score; CRT= Classification and Regression Trees; ITAT Score= Inpatient Triage Assessment and Treatment score; PEDIA score= Paediatric Early Death Index for Africa score

Table 1: Review framework according to the CHARMS checklist

Item	Criteria
Prognostic or diagnostic model	Prognostic model predicting in-hospital mortality.
Scope	Prognostic models to inform clinicians about the risk of deterioration or death.
Type of prediction models	Prognostic models with and/or without external validation.
Prediction target population	Children aged > 1 month to 15 years admitted in pediatric wards in developing countries
Outcome of interest	All-cause in-hospital mortality.
Prediction period	Any
Intended moment to apply the prediction tool	Prognostic model to be used in primary prevention to assess risk of deterioration and thus guide prevention/treatment.

Table 2: List of domains and signalling questions used for risk of bias assessment.

Domain	Signalling question
Participants selection	Were appropriate data sources used, e.g., cohort, RCT, or nested case-control study data?
	Were all inclusions and exclusions of participants appropriate?
Predictors	Were predictors defined and assessed in a similar way for all participants?
	Were predictor assessments made without knowledge of outcome data?
	Are all predictors available at the time the model is intended to be used?
Outcome	Was the outcome determined appropriately?
	Was a prespecified or standard outcome definition used?
	Were predictors excluded from the outcome definition?
	Was the outcome defined and determined in a similar way for all participants?
	Was the outcome determined without knowledge of predictor information?
Analysis	Was the time interval between predictor assessment and outcome determination appropriate?
	Were there a reasonable number of participants with the outcome?
	Were continuous and categorical predictors handled appropriately?
	Were all enrolled participants included in the analysis?
	Were participants with missing data handled appropriately?
	Was selection of predictors based on univariable analysis avoided?
	Were complexities in the data (e.g., censoring, competing risks, sampling of control participants) accounted for appropriately?
	Were relevant model performance measures evaluated appropriately?
	Were model overfitting, underfitting, and optimism in model performance accounted for?
Do predictors and their assigned weights in the final model correspond to the results from the reported multivariable analysis?

Reporting checklist for systematic review and meta-analysis.

Based on the PRISMA guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA reporting guidelines, and cite them as:

Moher D, Liberati A, Tetzlaff J, Altman DG, The PRISMA Group. Preferred Reporting Items for Systematic Reviews and Meta-Analyses: The PRISMA Statement

	Reporting Item	Page Number
Title		
	#1 Identify the report as a systematic review, meta-analysis, or both.	1

Abstract

1	Structured	#2	Provide a structured summary including, as applicable:	2
2				
3	summary		background; objectives; data sources; study eligibility criteria,	
4			participants, and interventions; study appraisal and synthesis	
5			methods; results; limitations; conclusions and implications of key	
6			findings; systematic review registration number	
7				
8				
9				
10				
11				
12				
13	Introduction			
14				
15				
16	Rationale	#3	Describe the rationale for the review in the context of what is	3
17			already known.	
18				
19				
20				
21				
22	Objectives	#4	Provide an explicit statement of questions being addressed with	3
23			reference to participants, interventions, comparisons, outcomes,	
24			and study design (PICOS).	
25				
26				
27				
28				
29	Methods			
30				
31				
32	Protocol and	#5	Indicate if a review protocol exists, if and where it can be	4
33	registration		accessed (e.g., Web address) and, if available, provide	
34			registration information including the registration number.	
35				
36				
37				
38				
39				
40	Eligibility criteria	#6	Specify study characteristics (e.g., PICOS, length of follow-up)	4
41			and report characteristics (e.g., years considered, language,	
42			publication status) used as criteria for eligibility, giving rational	
43				
44				
45				
46				
47				
48	Information	#7	Describe all information sources in the search (e.g., databases	N/A
49	sources		with dates of coverage, contact with study authors to identify	
50			additional studies) and date last searched.	
51				
52				
53				
54				
55	Search	#8	Present full electronic search strategy for at least one database,	5
56			including any limits used, such that it could be repeated.	
57				
58				
59				
60				

1	Study selection	#9	State the process for selecting studies (i.e., for screening, for	6
2			determining eligibility, for inclusion in the systematic review, and,	
3			if applicable, for inclusion in the meta-analysis).	
4				
5				
6				
7				
8	Data collection	#10	Describe the method of data extraction from reports (e.g., piloted	6
9	process		forms, independently by two reviewers) and any processes for	
10			obtaining and confirming data from investigators.	
11				
12				
13				
14				
15				
16	Data items	#11	List and define all variables for which data were sought (e.g.,	6
17			PICOS, funding sources), and any assumptions and	
18			simplifications made.	
19				
20				
21				
22				
23				
24	Risk of bias in	#12	Describe methods used for assessing risk of bias in individual	7
25	individual studies		studies (including specification of whether this was done at the	
26			study or outcome level, or both), and how this information is to	
27			be used in any data synthesis.	
28				
29				
30				
31				
32				
33				
34	Summary	#13	State the principal summary measures (e.g., risk ratio, difference	N/A
35	measures		in means).	
36				
37				
38				
39	Planned methods	#14	Describe the methods of handling data and combining results of	N/A
40	of analysis		studies, if done, including measures of consistency (e.g., I ²) for	
41			each meta-analysis.	
42				
43				
44				
45				
46				
47	Risk of bias	#15	Specify any assessment of risk of bias that may affect the	7
48	across studies		cumulative evidence (e.g., publication bias, selective reporting	
49			within studies).	
50				
51				
52				
53				
54	Additional	#16	Describe methods of additional analyses (e.g., sensitivity or	N/A
55	analyses		subgroup analyses, meta-regression), if done, indicating which	
56				
57				
58				
59				
60				

were pre-specified.

Results

Study selection	#17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram .	8
Study characteristics	#18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citation.	8
Risk of bias within studies	#19	Present data on risk of bias of each study and, if available, any outcome-level assessment (see Item 12).	11
Results of individual studies	#20	For all outcomes considered (benefits and harms), present, for each study: (a) simple summary data for each intervention group and (b) effect estimates and confidence intervals, ideally with a forest plot.	N/A
Synthesis of results	#21	Present the main results of the review. If meta-analyses are done, include for each, confidence intervals and measures of consistency.	N/A
Risk of bias across studies	#22	Present results of any assessment of risk of bias across studies (see Item 15).	11
Additional analysis	#23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	N/A

Discussion

1	Summary of	#24	Summarize the main findings, including the strength of evidence	12
2				
3	Evidence		for each main outcome; consider their relevance to key groups	
4				
5			(e.g., health care providers, users, and policy makers	
6				
7				
8				
9	Limitations	#25	Discuss limitations at study and outcome level (e.g., risk of bias),	15
10				
11			and at review level (e.g., incomplete retrieval of identified	
12				
13			research, reporting bias).	
14				
15				
16	Conclusions	#26	Provide a general interpretation of the results in the context of	16
17				
18			other evidence, and implications for future research.	
19				
20				
21				
22	Funding			
23				
24				
25	Funding	#27	Describe sources of funding or other support (e.g., supply of	17
26				
27			data) for the systematic review; role of funders for the systematic	
28				
29			review.	
30

Abstract

Objectives: To identify and appraise the methodological rigor of multivariable prognostic models predicting in-hospital paediatric mortality in low- and middle-income countries (LMIC).

Design: Systematic review of peer-reviewed journals.

Data sources: MEDLINE, CINAHL, Google Scholar, and Web of Science electronic databases since inception to August 2019.

Eligibility criteria: We included model development studies predicting in-hospital paediatric mortality in LMIC.

Data extraction and synthesis: This systematic review followed the CHARMS (Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies) framework. The risk of bias assessment was conducted using PROBAST (Prediction model Risk of Bias Assessment Tool). No quantitative summary was conducted due to substantial heterogeneity that was observed after assessing the studies included.

Results: Our search strategy identified a total of 4054 unique articles. Among these, 3545 articles were excluded after review of titles and abstracts as they covered non-relevant topics. Full texts of 509 articles were screened for eligibility, of which 15 studies reporting 21 models met the eligibility criteria. Based on the PROBAST tool, risk of bias was assessed in four domains; participant, predictors, outcome, and analyses. The domain of statistical analyses was the main area of concern where none of the included models was judged to be of low risk of bias.

Conclusion: This review identified 21 models predicting in-hospital paediatric mortality in LMIC. However, most reports characterising these models are of poor quality when judged against recent reporting standards due to a high risk of bias. Future studies should adhere to

1
2
3 standardized methodological criteria and progress from identifying new risk scores to validating
4
5 or adapting existing scores.

9

10 **Article summary**

11 **Strengths and limitations of this study**

- 12 • This is the first systematic review on methodological quality of prognostic models
13 predicting in-hospital paediatric mortality in resource-limited settings.
- 14 • We used a robust search strategy with no language restriction yielding a large number of
15 potentially eligible studies, hence it is unlikely that any potentially eligible study was not
16 included.
- 17 • No meta-analysis was conducted due to substantial heterogeneity in the included studies.
- 18 • We relied on what was reported to determine the risk of bias of the models.
- 19 • Google Translate was used to translate one study from French to English. It is therefore
20 possible that some statistical terminologies were not rendered correctly.

Introduction

Over recent decades, there has been considerable progress in improving child survival¹ but child mortality remains high in sub-Saharan Africa relative to the rest of the world.² Paediatric deaths in hospitalized children mostly occur soon after admission,³ and are caused by common conditions such as malaria, pneumonia, and diarrhoeal diseases among others, which are readily treatable by cost-effective interventions.³⁻⁵ In low- and middle-income countries (LMIC), clinicians often use a set of clinical signs as recommended in the guidelines by World Health Organization (WHO) to identify patients at risk of deterioration while making decisions on appropriate treatment.⁶ Clinical criteria recommended by WHO were developed following expert recommendations based on review of evidence from studies reporting risk factors for mortality. Prognostic models, which use statistical equations to predict patients' risk based on the combination of prognostic factors, may improve clinicians' ability to identify high-risk patients and thus improve outcomes.⁷

Various clinical prediction models for hospitalised paediatric patients have been developed over the last 3 decades,⁸ however, there are doubts whether appropriate methodology has been used in their development.⁹ Notably, none are currently recommended for use in existing paediatric clinical practice guidelines in LMIC and systematic reviews of the methodology used in their development have been strongly recommended.¹⁰ This systematic review addresses this need and aims at identifying and summarizing existing studies reporting prognostic models for predicting in-hospital paediatric mortality in LMIC. Specifically, the research summarises the evidence from the published studies and appraises the methodological rigor of each existing model.

Methods

Protocol and registration

As recommended, a research protocol for this systematic review was published in a peer-reviewed journal,¹¹ and we also registered at PROSPERO (International Prospective Register of Systematic Reviews) (CRD42018088599).¹² This work is reported as per guidelines by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses).¹³

Eligibility criteria

Reports were eligible for inclusion if they met the following criteria:

1. Study design: peer-reviewed studies whose design was either a randomized controlled trial, cohort (prospective or retrospective), cross-sectional, or case-control observational study.
2. Outcome: studies fitting models predicting all-cause in-hospital mortality in a general paediatric ward were included. Studies predicting post-discharge mortality, trauma or operative mortality were excluded.
3. Target population and setting: studies on children aged over 1-month old admitted in general paediatric wards within LMIC as defined by the World Bank¹⁴ were included. Studies whose predictive models were targeting patients in intensive care unit (ICU) or high dependency unit (HDU) were excluded because these facilities are largely unavailable in low-resource settings. We also excluded studies whose predictive models targeted uncommon conditions in children e.g., chronic kidney disease, cancer, diabetes.

1
2
3 However, if a study focused on one of the common childhood illnesses such as malaria,
4 pneumonia, meningitis, anaemia, and diarrhoea/dehydration³, then it was included.
5
6

- 7
8 4. Type of studies: we included studies whose main objective was deriving a predictive
9 model(s) or scoring system(s). We excluded commentaries, editorials, expert views,
10 conference proceedings, case reports, case-series, reviews and explanatory studies that
11 mainly generate hypothesis¹⁵.
12
13
14
15
16 5. Models: studies that reported multivariable model with at least 2 variables/predictors
17 were included.
18
19
20
21 6. Full text and language: We excluded studies that were not available in full text. Non-
22 English language studies were translated using Google Translate. Hence no language
23 restriction was made.

31 *Search strategy*

32
33 As recommended by CHARMS (Checklist for critical Appraisal and data extraction for
34 systematic Reviews of prediction Modelling Studies) checklist¹⁶, we came up with seven key
35 items (supplementary file 1 Table 1) applicable to our study that guided the framing of the search
36 strategy, review aim and eligibility criteria.
37
38
39
40

41
42 We used Medical Subject Headlines (MeSH) where appropriate and keywords to identify articles
43 with prognostic models relevant for this review. A search of articles was conducted in
44 MEDLINE, Google Scholar, and CINAHL (via EbscoHost) since inception to August 2019. We
45 also performed a search in Web of Science to identify additional reports that cited the identified
46 studies. Reference lists of all identified articles were searched manually to identify other
47 potentially eligible studies.
48
49
50
51
52
53
54
55

1
2
3 We manually searched reference lists of all relevant articles to identify additional eligible
4 studies. Final search results were collated in EndNoteX7™ bibliography tool. Detailed search
5 terms and strategy are provided in supplementary file 1 Table 2.
6
7

8 9 10 ***Screening of articles***

11
12
13 Prior to screening titles and abstracts, 2 reviewers (MO and LM) standardized the approach to be
14 used in the process of screening. We used a sample of 30 search results to train and familiarize
15 reviewers with the screening process. Titles and abstracts of the studies were screened by the two
16 reviewers. Discrepancies were resolved via discussion and, when necessary, a final decision was
17 adjudicated by a third reviewer (JA).
18
19
20
21
22
23

24 25 ***Data Extraction***

26
27 Data were extracted from relevant articles in accordance with the CHARMS. From each study
28 included, data were extracted on participant enrolment, study design, study population
29 characteristics, location, sample size, number and selection of predictors, study dates, handling
30 of continuous predictors, missing data, method of modelling (e.g. logistic regression, survival),
31 verification of model assumptions, internal validation methods (e.g. random split of data,
32 resampling techniques); model presentation (e.g. nomogram, score chart, or regression formula
33 with coefficients); and model performance metrics including discrimination -area under the
34 receiver operating characteristic curve (AUC) with 95% confidence interval (CI); calibration;
35 classification measures such as sensitivity, specificity, positive, and negative predictive values.
36
37 We further investigated from literature to determine if included models have been externally
38 validated elsewhere. For articles that described development of multiple prognostic models, we
39 treated each model separately whenever the predictor-outcome association produced different
40

1
2
3 model estimates. For each study, extracted data elements were compared between two reviewers
4
5 (MO & LM), and any disagreements were resolved by discussion with the third reviewer (JA).
6

7
8 No quantitative summary was conducted due to substantial heterogeneity that was observed after
9
10 assessing studies included.

11 ***Assessment of methodological quality***

12
13
14
15 The *risk of bias* (shortcomings in the predictive models that might lead to unreliable predictions)
16
17 of the included studies was assessed based on the Prediction study Risk Of Bias Assessment
18
19 Tool (PROBAST).^{17 18} We assessed the *risk of bias* (RoB) for each model in four domains:
20
21 participant selection (e.g. study design), predictors (e.g. assessment of candidate and final model
22
23 predictors), outcome, and analysis (e.g. handling of missing data, the handling of continuous
24
25 predictors) see supplementary file 1 Table 3. For each domain, signalling questions had five
26
27 possible answers: yes; probably yes; probably no; no; and no information. Any positive answer
28
29 (yes, or probably yes) suggests low RoB. Each domain had three possible outcomes: low; high;
30
31 or unclear RoB. Using these domain outcomes, we came up with an overall judgement of
32
33 RoB for each model. As recommended by PROBAST, if a prediction model was judged as low
34
35 on all four domains, we assigned it an overall judgment of “low RoB”. If a model was rated as
36
37 high at least in one domain, we judged it as having “high RoB”. If at least one domain of the
38
39 model was rated as unclear and the rest of the domains rated as low, it was judged as having
40
41 “unclear RoB”.
42
43
44
45

46 ***Patient and public involvement***

47
48
49
50 No patient or public involvement.
51
52

Results

Characteristics of the included studies

Our search strategy identified a total of 4054 unique articles, 3545 articles were excluded after review of titles and abstracts as they reported non-relevant topics. Full texts of 509 articles were screened for eligibility, of which 15 primary studies reporting 21 developed models met the eligibility criteria (Figure 1). The eligible studies analysed data for patients who were below 15 years of age with median mortality being 6.7% (range 1.2% to 43.9%).^{19 20} While majority of the models were developed for general cases in paediatric wards (n=9), some were tailored for specific paediatric groups defined by common diagnoses such as febrile illness (n=1),²¹ malaria (n=2),^{22 23} pneumonia (n=4),^{19 24-26} malnutrition (n=2)^{27 28} and other infectious diseases (n=3) (see supplementary file 2).

Most of the included studies have been published post year 2000 (n = 20) except for one study²⁷ published in 1996. The latest data used in the models under review were from 2016 to 2017 by Rosman *et al.*²⁹ and the oldest data were utilized by Drimax *et al.*²⁷ from 1986 to 1988.

Five reports of the 15 included studies utilized data from at least two hospitals of which 3 studies^{21 22 26} were conducted in multiple countries including sub-Saharan Africa and Asian countries (Figure 2). Of the reviewed studies, most of the information we were abstracting were either not reported or were partially reported, an indication of non-adherence to the TRIPOD (Transparent Reporting of a Multivariable Prognostic Model for Individual Prognosis or Diagnosis) guidelines.^{30 31}

Summary of issues in methodology of the reviewed models

Candidate predictors

There were 61 distinct predictors used in the final reported models (a median of 7 predictors in any one model). Initial selection of the candidate predictors was mostly based on univariable analysis except for three studies^{21 25 27} where the selection was based on literature reviews or clinical relevance. Backward stepwise selection method was used in 6 models in a multivariable analysis to determine final model predictors. Commonly included predictors in the final models included altered consciousness, malnutrition indicators, vital signs, and signs of respiratory distress (see Figure 3). Some models included predictors that were either not easy to obtain or required laboratory techniques. Of the 13 models including continuous predictors, 8 models categorized continuous predictors where a continuous scale would have been possible. Two out of 13 models applied other techniques such as fractional polynomial²¹ and restricted cubic splines²⁸ to determine the suitable functional form of the continuous predictors (see supplementary file 2).

Sample size, events per variable (EPV) and missing data

Sample size ranged from 168²⁹ to 50249³² with a median of 1307. The median EPV was 21(IQR 8.3 – 32.5) of which 7 models had less than 10 EPVs, suggestive of insufficient sample sizes which is prone to over-fitting. For instance, 60 deaths were reported in the dataset used to develop *PEDIA-Immediate* score in the study by Berkley *et al.* In reference to the rule that a study developing a predictive model should have a minimum of 10 events for each independent predictor in a prognostic model,³³ a model with, at the most, 6 predictors should have been considered but 10 predictors were considered instead hence making EPV 6.

1
2
3 Proportions of missing data was not always reported. Handling of missing data varied across the
4 reviewed studies as follows: 6 models did not report handling of missing data; 8 used complete
5 case analysis; 4 used multiple imputations by chained equations; and one study²⁸ used single
6 imputation.
7
8
9
10
11

12 Model development

13 Majority of the studies applied logistic regression, one study²¹ used Cox regression, one study²⁰
14 used Spiegelhalter/Knill-Jones method and another study²³ used a machine learning technique
15 (classification and regression trees (CRT)) in model development. Verification of model
16 assumptions was not reported in most of the studies. For instance, George *et al*²¹ despite utilizing
17 Cox regression to develop their model, did not report the verification of proportional hazard
18 assumption nor explore the possibility of competing risks as recommended³⁴. Other regression
19 assumptions e.g. multicollinearity was equally not reported. However, since backward
20 elimination method disregards redundant variables, we inferred the satisfaction of
21 multicollinearity assumption if this method was applied.³⁵ Five studies developed models using
22 data from different countries/centres but none of them clustered their analysis by source of data
23 in a multilevel model to account for heterogeneity. Ignoring clustering leads to a biased predictor
24 effect.³⁶

44 Model performance evaluation & presentation

45 Performance measures (both calibration and discrimination) were poorly reported in most of the
46 studies and in most cases (n=20) AUC for discrimination was reported. Performance of the
47 derived models was evaluated in 12 models using either split-sample, resampling methods, or
48 separate datasets. Except for the model derived by George *et al*,²¹ all other models did not report
49 both apparent discrimination (without any adjustment for optimism) and optimism-corrected
50

1
2
3 discrimination measures. Despite inadequate reporting of the models' performance, 16 models
4 reported AUCs ≥ 0.80 , an indication of promising models. Apart from the following exceptions;
5
6 *Lambarene Organ Dysfunction (LOD) score*,²² *Paediatric Early Death Index for Africa (PEDIA)*
7
8 *score*,²⁰ *Signs of Inflammation in Children that Kill (SICK) score*,³⁷ *Respiratory Index of Severity*
9
10 *in Children (RISC) score*,¹⁹ and *Modified Respiratory Index of Severity in Children (mRISC)*
11
12 *score*,²⁴ other scores have not been externally validated (by independent investigators using
13
14 diverse populations). Only 2 studies^{25 38} developing 4 models provided a full model formula
15
16 (both coefficients and intercept/baseline function) in their results as recommended.^{30 31} While
17
18 most of the models (n=17) were presented as simplified integer scores, only a few were assigned
19
20 weights according to the regression coefficients.
21
22
23
24
25

26 27 **Risk of bias (RoB) assessment**

28
29
30 Based on the PROBAST tool, RoB was assessed in four domains; participants, predictors,
31
32 outcome, and analyses. Figure 4 summarizes the RoB assessment across all models included in
33
34 this review where the domain of outcome was deemed to be of low RoB in all models. The
35
36 domain of statistical analyses was the main area of concern where 19 out of 21 models did not
37
38 report comprehensive details of model development as expected to warrant a proper risk of bias
39
40 assessment using the 9 signalling questions under analyses domain. As a result, these models
41
42 were rated to be of unclear RoB under the domain of analyses (see Figure 5). Details on how
43
44 models were scored against each of the PROBAST criterion (20 signalling questions) across four
45
46 domains are provided in the supplementary file 3. In the overall judgement of RoB, 9 out of 21
47
48 models were judged to be of high risk of bias because at least one out of four domains in these
49
50 models were rated as high RoB. The remaining models (12/21) were judged to be of unclear RoB
51
52 on account of being rated low and unclear RoB in the domains. Two models^{24 26} were judged to
53
54
55
56
57

1
2
3 be of high RoB because at least one of the domains was rated high RoB. No model was rated low
4
5 RoB in all four domains.
6

7 8 **Discussion** 9

10 11 **Summary of key findings** 12

13
14 We conducted a systematic review to identify published scores predicting in-hospital mortality
15
16 for paediatrics in resource-limited countries. Fifteen studies that described the development of 21
17
18 prognostic models were identified. We describe characteristics of these studies as well as the
19
20 methodological quality of the included models by using agreed recent guidelines applicable to
21
22 predictive models. We have identified several important quality deficiencies such as inadequate
23
24 reporting and other methodological concerns, including poor handling of missing data,
25
26 automated selection of predictors, categorization of continuous predictors, inadequate EPV and
27
28 the poor presentation of the proposed model for use. As a result, no model was found to be of
29
30 good methodological quality and consequently judged to be potentially high or unclear risk of
31
32 bias in predictions (Figure 5).
33
34
35
36

37
38 Our findings suggest that predictive models fail to meet recently agreed methodological criteria
39
40 in various ways. Firstly, in this review we observed that univariable analysis was routinely used
41
42 in 18 out of 21 models in the selection of candidate predictors to be used in a multivariable
43
44 analysis. This strategy tends to leave out possibly important prognostic factors which might be
45
46 insignificant in a univariable analysis but turn out to be significant when combined with other
47
48 predictors.^{30 31} *A priori* selection of predictors using expert opinion, clinical intuition or literature
49
50 is recommended for this purpose,^{39 40} however only three studies in this review employed this
51
52 approach.^{21 25 27}
53
54
55
56
57

1
2
3 Small sample sizes in model development can lead to poor predictive performance, over-fitting,
4 and biased effect estimates. Prognostic models must have a minimum of 10 events per candidate
5 predictor, as this is the accepted norm⁴¹⁻⁴³ and underpowered models arising from inadequate
6 events per variable (EPV) increases the possibility of spurious results.³³ In this review, 7/21
7 models had inadequate sample sizes (EPV<10) and there was no information on whether
8 bootstrapping, which serves to reduce overfitting was used in these models.⁴⁴
9

10 Just like most of the epidemiological studies, missing data is a common problem which is solved
11 using multiple imputation or other appropriate approaches, but this was rarely the case in the
12 model development studies under this review. For instance, 8/21 models used complete case
13 analysis (CCA), 4/21 used multiple imputation under the assumption of missing at random
14 (MAR), and 6/21 models did not report how missing data were handled and therefore we
15 assumed CCA was used. Following Harrell's guidelines,⁴⁵ CCA should only be used if the
16 percentage of missingness is < 5% but the appropriateness of the CCA approach could not be
17 ascertained as most of the included studies failed to report the proportion of missing data per
18 variable. Inappropriate use of CCA results in use of only a small subset of the data which cannot
19 be regarded as a random sample from the target population unless data are missing completely at
20 random(MCAR),⁴⁶ a mechanism which is rare in practice.⁴⁷ Consequently, there are concerns
21 about possible loss of precision in inferences and the potential biases of the estimated
22 parameters⁴⁸ in the models employing CCA. While Multiple Imputation by Chained Equations
23 (MICE) is the principled method of handling missing data, implementing this method when the
24 data are not MAR could result in biased model estimates.⁴⁹ As a result, sensitivity analyses of the
25 resultant imputations is recommended to investigate the departure from MAR assumption.⁵⁰
26 However, this was not the case in the studies that performed imputations on their data. Finally,

1
2
3 handling of continuous predictors was also a concern in this review. Of the 13 models including
4 continuous predictors, 8 models^{19 20 24-27 37 51} categorized continuous predictors where a
5 continuous scale would have been possible. While this approach is intuitive to most researchers,
6
7 continuous scale would have been possible. While this approach is intuitive to most researchers,
8
9 its simplicity comes at a considerable cost of predictive performance.⁵² The resulting prognostic
10 models have been shown to have poor predictive accuracy because of the loss of statistical power
11 and information. It is recommended that the nature of continuous data should be retained or be
12 handled by using techniques e.g. regression splines, flexible parametrizations such as fractional
13 polynomial, or apply non-parametric techniques such as locally estimated scatterplot smoothing
14 (LOESS) functions.^{52 53} In this review, appropriate methods of transforming continuous data was
15 done by only 2 studies^{21 28} which applied fractional polynomial and restricted cubic splines.
16
17 Sixteen models attained the discrimination metric of above 80%, an indicator of promising
18 models. However, given that the median mortality of the included studies was 6.7%, the
19 performance reported should be interpreted with caution on account of heavily imbalanced data
20 as a result of the rare nature of the outcome of interest. For instance, in a study with a mortality
21 rate of 5%, a model predicting no deaths could easily attain 95% accuracy which could be
22 potentially misleading^{34 54}. Therefore, authors should report additional measures of model
23 performance such as model sensitivity, specificity, accuracy, positive and negative predictive
24 values for models to be contextualized appropriately.

45 **Comparison with Other Studies**

46
47
48 Methods used to assess quality measures of the included models in the current study have been
49 applied previously to critically evaluate the quality of predictive models in other specialties.⁵⁵⁻⁵⁷
50
51 Just like the findings of this review, other previous reviews^{9 58-60} describing the development of
52 prognostic models highlighted many flaws including inappropriate statistical analyses, poor
53
54
55
56
57

1
2
3 reporting of important clinical and methodological information needed for validation of the
4 model, and lack of external validations. Detailed and transparent reporting of the methods used
5 in model development is one of the core principles of integrity in research because this is the
6 only way the research community is able to judge the reliability of research findings, and the
7 assessment of risk of bias.⁶¹ Incomplete reporting of clinical models limits future studies on
8 prognostic research from building on the information of already existing models. This has been
9 marked as an important source of wasted research efforts.⁶² For example, external validation of
10 prognostic models requires a full model formula to enable direct estimation of survival
11 probabilities.³¹ However, this was presented in only 4 models . Five models ^{19 20 22 24 37} that were
12 reported to have undergone external validation did not report full model formula as required. It is
13 therefore not clear whether authors of these external validation studies applied model coefficients
14 to the external datasets, or they estimated new model coefficients (essentially model
15 redevelopment). Thus, this review highlights the need for researchers to adhere to the TRIPOD
16 guidelines that were created to help authors of prognostic models write complete and transparent
17 reports. Of note, the quality of clinical predictive models does not appear to have improved over
18 time as previous reviews from 1996,⁶³ 1997,⁶⁴ 2001,⁶⁵ 2005,⁶⁶ 2011,⁸ 2012,⁶⁷ 2016,^{68 69} 2017,⁷⁰
19 to 2019⁷¹ have consistently identified suboptimal methodologies in the development of the
20 predictive models especially in the domain of analysis. Poorly derived models may result in
21 overoptimistic results and misleading performances. Presumably there are reasons why many
22 prognostic models are of poor quality, including pressure to publish new predictive model
23 regardless of the clinical value of the resultant model⁷², and inadequate biostatistical support to
24 investigators. As observed by one of the reviewers of this study, some of the issues identified in
25 this review such as absence of the details on the model development process can be corrected

3 during the review and the editorial process by the journals publishing the work. There is
4
5 therefore a role for editorial process for promoting best practices and recommendations of
6
7 developing predictive models stated in the TRIPOD statement and ensuring compliance by
8
9 authors as part of checklist for submission.
10
11

12 13 **Implications of this study**

14
15
16 Prognostic model development pipeline include development, validation (internal and external),
17
18 impact assessment and implementation. Most of the included models are still in the first step of
19
20 the pipeline. This suggests that researchers focus more on deriving new models, often using
21
22 similar prognostic factors, rather than validating and improving existing prognostic models. This
23
24 leaves healthcare policy makers with doubts as to which model to recommend in their setting. It
25
26 is now time to move the prognostic research to the next step (external validation). Large patient-
27
28 level datasets such as that of the Clinical Information Network (CIN)³ which has been collected
29
30 over time from a number of referral hospitals now exist in Kenya and it has been used to answer
31
32 a number of salient clinical questions relevant across a range of resource-limited setting⁷³⁻⁷⁵.
33
34

35
36
37 Future studies on prognostic research should leverage such datasets to externally validate
38
39 competing models identified in this review for comparative performances as recommended by
40
41 Collins *et al*,⁷⁶ and if necessary, predictive performance of such models should be improved by
42
43 addition of new prognostic factors. We also noted that most of the included models simplified
44
45 the original predictor coefficients by rounding them to a nearest integer. This practice has an
46
47 implication on model performance during external validation due to loss in predictive accuracy
48
49 arising from rounding coefficients to nearest integers.⁴⁷
50
51

52
53 We now provide guidance on methodological concerns about the candidate predictors as noted in
54
55 this review. While considering potential candidate predictors to include in the prediction model,
56
57

1
2
3 researchers should focus on the predictors that will be available at the time the prediction is
4 made. We acknowledge that some predictors obtained from invasive procedures e.g. C-reactive
5 protein, blood gas analyses, blood or cerebrospinal fluid culture, etc might have a higher
6
7 predictive value for mortality compared to predictors derived from subjective clinical
8
9 assessments, however in resource-limited settings results of such laboratory tests typically take
10
11 days to be reported or resources might not be available to perform such tests in many hospitals.
12
13 Consequently, models utilising such variables might not be useful to clinicians to make a
14
15 decision at typical emergency departments in LMIC. Screening of model candidate predictors
16
17 based on the bivariate associations whereby predictors are selected if they meet some p -value
18
19 threshold (commonly 0.05) have been strongly discouraged previously^{77 78}. Categorising
20
21 continuous model predictors is a common practice by researchers however this practice discards
22
23 a lot of information and its assumptions are rarely clinically plausible.³⁴ Finally, there is a risk of
24
25 overfitting if the model includes more predictors than the dataset can support. The ratio of the
26
27 number of outcomes to the number of predictors (events per variable) have been discussed
28
29 extensively in methodological papers elsewhere^{79 80} and it has been recommended that ratio of
30
31 the EPV should be at least 10.
32
33
34
35
36
37
38
39
40
41
42
43
44

45 **Strengths and limitations**

46
47 To our knowledge, this is the first review identifying models predicting in-hospital paediatric
48
49 mortality in resource-limited settings. Our robust search strategy yielded a large number of
50
51 potentially eligible studies, hence it is unlikely that any potentially eligible study was not
52
53 included. The quality of included models was assessed based on recent reporting standards and
54
55
56
57

1
2
3 applied to the identified studies. For instance, if no mention was made of internal validation or
4
5 even verification of the model assumptions, it could not be determined whether these crucial
6
7 steps of model development were carried out or not. Thus, models that could have been
8
9 otherwise rated as low risk of bias were rated as either unclear or high risk of bias in each
10
11 domain. The PROBAST's analysis domain has most (9 out of 20) of the signalling questions and
12
13 any given model in this domain had much higher chance to be defined as high risk as long as
14
15 there was one negative (no or probably no) answer. This strict criterion led to all models being
16
17 classified as either unclear or high risk of bias and therefore metanalysis was not performed. We
18
19 acknowledge that if we somewhat relaxed this decision rule, our conclusion could change.
20
21 Despite this, we still hold that authors should adhere to guidelines of transparent and complete
22
23 reporting of any proposed prognostic model to facilitate its external validation and subsequent
24
25 application in practice. Finally, we used Google Translate to interpret a study by Bitwe et al⁵¹
26
27 from French to English. It is possible that some statistical terminologies were not rendered
28
29 correctly, or some model characteristics were lost in translation.
30
31
32
33
34

35 **Conclusion**

36
37 Rigorously developed and robustly validated promising predictive models have the potential for
38
39 improving child survival in resource-limited countries. This review identified models predicting
40
41 in-hospital mortality for paediatrics. However, none of them is of good quality. Our research
42
43 highlights the need to improve on the identified quality deficiencies when developing prognostic
44
45 models in the future by adhering to existing generally accepted standardized methodological
46
47 criteria. Majority of the derived models have not been externally validated as required.
48
49

50
51 Inadequate reporting observed in the included models hinders rigorous external validation by
52
53 other researchers in addition to undermining their application in practice. Rather than developing
54
55
56
57

1
2
3 new prognostic models, researchers should carry out comprehensive joint external validation of
4 the identified models using large datasets ideally collected over extended time periods and
5
6 different locations. This will allow head-to-head comparisons and adaptation of the competing
7
8 models, if necessary, to ascertain their generalizability.
9

Table 1: Systematic review framework as recommended by CHARMS checklist

Item	Criteria
Prognostic or diagnostic model	Prognostic model predicting in-hospital mortality.
Scope	Prognostic models to inform clinicians about the risk of deterioration or death.
Type of prediction models	Prognostic models with and/or without external validation.
Prediction target population	Children aged > 1 month to 15 years admitted in pediatric wards in developing countries
Outcome of interest	All-cause in-hospital mortality.
Prediction period	Any
Intended moment to apply the prediction tool	Prognostic model to be used in primary prevention to assess risk of deterioration and thus guide prevention/treatment.

KEY:

CHARMS= Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies

Table 2: Search terms for prognostic models

Search ID	Sub-heading	Search Terms
S4	Children	paediatric* OR pediatric* OR (MH "Pediatrics+") OR child*
S3	Hospital based	(MH "Hospitals+") OR hospital*
S2	Low-income countries	(MH "Developing Countries+") OR (MH "Africa+") OR TI ("low income" OR "low and middle income" OR "LMIC" OR "LIC" OR "limited resource*" OR "poor resource*" OR "resource* poor" OR ("developing countries") OR ("developing nations") OR ("third world") OR "resource-constrained" OR ("global south"))
S1	Predictive models	prognos* OR (MH "prognosis") OR (Predict* AND (Outcome* OR Risk* OR Model* OR Mortality OR Index OR Rule* OR decision* OR scor*)) OR "risk score" OR "scor* system" OR "logistic model*" OR "risk prediction" OR "risk calculation" OR "risk assessment" OR "c statistic" OR discrimination OR calibration OR AUC OR "area under the curve" OR "area under the receiver operator characteristic curve"

Table 3: List of domains and signaling questions used for assessment of risk of bias according to the PROBAST tool.

Domain	Signalling question
Participants selection	Were appropriate data sources used, e.g., cohort, RCT, or nested case–control study data?
	Were all inclusions and exclusions of participants appropriate?
Predictors	Were predictors defined and assessed in a similar way for all participants?
	Were predictor assessments made without knowledge of outcome data?
	Are all predictors available at the time the model is intended to be used?
Outcome	Was the outcome determined appropriately?
	Was a prespecified or standard outcome definition used?
	Were predictors excluded from the outcome definition?
	Was the outcome defined and determined in a similar way for all participants?
	Was the outcome determined without knowledge of predictor information?
	Was the time interval between predictor assessment and outcome determination appropriate?
Analysis	Were there a reasonable number of participants with the outcome?
	Were continuous and categorical predictors handled appropriately?
	Were all enrolled participants included in the analysis?
	Were participants with missing data handled appropriately?
	Was selection of predictors based on univariable analysis avoided?
	Were complexities in the data (e.g., censoring, competing risks, sampling of control participants) accounted for appropriately?
	Were relevant model performance measures evaluated appropriately?
	Were model overfitting, underfitting, and optimism in model performance accounted for?
	Do predictors and their assigned weights in the final model correspond to the results from the reported multivariable analysis?

Reporting checklist for systematic review and meta-analysis.

Based on the PRISMA guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA reporting guidelines, and cite them as:

Moher D, Liberati A, Tetzlaff J, Altman DG, The PRISMA Group. Preferred Reporting Items for Systematic Reviews and Meta-Analyses: The PRISMA Statement

	Reporting Item	Page Number
Title		
	#1 Identify the report as a systematic review, meta-analysis, or both.	1

Abstract

1	Structured	#2	Provide a structured summary including, as applicable:	2
2				
3	summary		background; objectives; data sources; study eligibility criteria,	
4			participants, and interventions; study appraisal and synthesis	
5			methods; results; limitations; conclusions and implications of key	
6			findings; systematic review registration number	
7

9				
10				
11				
12				
13	Introduction			
14				
15				
16	Rationale	#3	Describe the rationale for the review in the context of what is	3
17			already known.	
18				
19				
20				
21				
22	Objectives	#4	Provide an explicit statement of questions being addressed with	3
23			reference to participants, interventions, comparisons, outcomes,	
24			and study design (PICOS).	
25				
26				
27				
28				
29	Methods			
30				
31				
32	Protocol and	#5	Indicate if a review protocol exists, if and where it can be	4
33	registration		accessed (e.g., Web address) and, if available, provide	
34			registration information including the registration number.	
35				
36				
37				
38				
39				
40	Eligibility criteria	#6	Specify study characteristics (e.g., PICOS, length of follow-up)	4
41			and report characteristics (e.g., years considered, language,	
42			publication status) used as criteria for eligibility, giving rational	
43				
44				
45				
46				
47				
48	Information	#7	Describe all information sources in the search (e.g., databases	N/A
49	sources		with dates of coverage, contact with study authors to identify	
50			additional studies) and date last searched.	
51				
52				
53				
54				
55	Search	#8	Present full electronic search strategy for at least one database,	5
56			including any limits used, such that it could be repeated.	
57				
58				
59				
60				

1	Study selection	#9	State the process for selecting studies (i.e., for screening, for	6
2			determining eligibility, for inclusion in the systematic review, and,	
3			if applicable, for inclusion in the meta-analysis).	
4				
5				
6				
7				
8	Data collection	#10	Describe the method of data extraction from reports (e.g., piloted	6
9	process		forms, independently by two reviewers) and any processes for	
10			obtaining and confirming data from investigators.	
11				
12				
13				
14				
15				
16	Data items	#11	List and define all variables for which data were sought (e.g.,	6
17			PICOS, funding sources), and any assumptions and	
18			simplifications made.	
19				
20				
21				
22				
23				
24	Risk of bias in	#12	Describe methods used for assessing risk of bias in individual	7
25	individual studies		studies (including specification of whether this was done at the	
26			study or outcome level, or both), and how this information is to	
27			be used in any data synthesis.	
28				
29				
30				
31				
32				
33				
34	Summary	#13	State the principal summary measures (e.g., risk ratio, difference	N/A
35	measures		in means).	
36				
37				
38				
39	Planned methods	#14	Describe the methods of handling data and combining results of	N/A
40	of analysis		studies, if done, including measures of consistency (e.g., I ²) for	
41			each meta-analysis.	
42				
43				
44				
45				
46				
47	Risk of bias	#15	Specify any assessment of risk of bias that may affect the	7
48	across studies		cumulative evidence (e.g., publication bias, selective reporting	
49			within studies).	
50				
51				
52				
53				
54	Additional	#16	Describe methods of additional analyses (e.g., sensitivity or	N/A
55	analyses		subgroup analyses, meta-regression), if done, indicating which	
56				
57				
58				
59				
60				

were pre-specified.

Results

Study selection	#17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram .	8
Study characteristics	#18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citation.	8
Risk of bias within studies	#19	Present data on risk of bias of each study and, if available, any outcome-level assessment (see Item 12).	11
Results of individual studies	#20	For all outcomes considered (benefits and harms), present, for each study: (a) simple summary data for each intervention group and (b) effect estimates and confidence intervals, ideally with a forest plot.	N/A
Synthesis of results	#21	Present the main results of the review. If meta-analyses are done, include for each, confidence intervals and measures of consistency.	N/A
Risk of bias across studies	#22	Present results of any assessment of risk of bias across studies (see Item 15).	11
Additional analysis	#23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	N/A

Discussion

1	Summary of	#24	Summarize the main findings, including the strength of evidence	12
2				
3	Evidence		for each main outcome; consider their relevance to key groups	
4				
5			(e.g., health care providers, users, and policy makers	
6				
7				
8				
9	Limitations	#25	Discuss limitations at study and outcome level (e.g., risk of bias),	15
10				
11			and at review level (e.g., incomplete retrieval of identified	
12				
13			research, reporting bias).	
14				
15				
16	Conclusions	#26	Provide a general interpretation of the results in the context of	16
17				
18			other evidence, and implications for future research.	
19				
20				
21				
22	Funding			
23				
24				
25	Funding	#27	Describe sources of funding or other support (e.g., supply of	17
26				
27			data) for the systematic review; role of funders for the systematic	
28				
29			review.	
30

Abstract

Objectives: To identify and appraise the methodological rigor of multivariable prognostic models predicting in-hospital paediatric mortality in low- and middle-income countries (LMIC).

Design: Systematic review of peer-reviewed journals.

Data sources: MEDLINE, CINAHL, Google Scholar, and Web of Science electronic databases since inception to August 2019.

Eligibility criteria: We included model development studies predicting in-hospital paediatric mortality in LMIC.

Data extraction and synthesis: This systematic review followed the CHARMS (Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies) framework. The risk of bias assessment was conducted using PROBAST (Prediction model Risk of Bias Assessment Tool). No quantitative summary was conducted due to substantial heterogeneity that was observed after assessing the studies included.

Results: Our search strategy identified a total of 4054 unique articles. Among these, 3545 articles were excluded after review of titles and abstracts as they covered non-relevant topics. Full texts of 509 articles were screened for eligibility, of which 15 studies reporting 21 models met the eligibility criteria. Based on the PROBAST tool, risk of bias was assessed in four domains; participant, predictors, outcome, and analyses. The domain of statistical analyses was the main area of concern where none of the included models was judged to be of low risk of bias.

Conclusion: This review identified 21 models predicting in-hospital paediatric mortality in LMIC. However, most reports characterising these models are of poor quality when judged against recent reporting standards due to a high risk of bias. Future studies should adhere to

1
2
3 standardized methodological criteria and progress from identifying new risk scores to validating
4
5 or adapting existing scores.

9

10 **Article summary**

11 **Strengths and limitations of this study**

- 12 • This is the first review on methodological rigor of models predicting paediatric mortality
13 in resource-limited settings.
- 14 • We used a robust search strategy with no language restriction yielding many potentially
15 eligible studies.
- 16 • Due to substantial heterogeneity in the models included no meta-analyses was
17 conducted.
- 18 • We relied on what was reported to determine the risk of bias in prognostic models
19 included.
- 20 • Google Translate was used to translate one study from French to English.

Introduction

Over recent decades, there has been considerable progress in improving child survival¹ but child mortality remains high in sub-Saharan Africa relative to the rest of the world.² Paediatric deaths in hospitalized children mostly occur soon after admission,³ and are caused by common conditions such as malaria, pneumonia, and diarrhoeal diseases among others, which are readily treatable by cost-effective interventions.³⁻⁵ In low- and middle-income countries (LMIC), clinicians often use a set of clinical signs as recommended in the guidelines by World Health Organization (WHO) to identify patients at risk of deterioration while making decisions on appropriate treatment.⁶ Clinical criteria recommended by WHO were developed following expert recommendations based on review of evidence from studies reporting risk factors for mortality. Prognostic/predictive models use statistical equations to predict high-risk patients based on the combination of risk factors. Use of these models by clinicians may improve patients' outcomes by enhancing clinicians' ability in identifying patients at the risk of deterioration.⁷ Several prognostic models for hospitalised children have been published over the last 3 decades,⁸ however, there are doubts as to whether authors of these models used the appropriate methodology in their development.⁹ Notably, in the current clinical practice guidelines, none of these models have been recommended for use in resource-limited setting and reviews of the methodology utilized in their development have been highly recommended.¹⁰ This systematic review addresses this need and aims at identifying and summarizing existing studies reporting prognostic models or scoring systems predicting in-hospital paediatric mortality in LMIC. Specifically, the research summarises the evidence from the published studies and appraises the methodological rigor of each existing model.

Methods

Protocol and registration

As recommended, a research protocol for this review was published in a peer-reviewed journal,¹¹ and is also registered with the International Prospective Register of Systematic Reviews (PROSPERO) the registration number is CRD42018088599.¹² This study is reported as per guidelines by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA).¹³

Eligibility criteria

We used the following eligibility criteria for inclusion of articles:

1. Study design: we included peer-reviewed studies whose study design was either a case-control, cohort (prospective or retrospective), cross-sectional, or randomized controlled trial.
2. Outcome: we included studies predicting all-cause in-hospital mortality. Studies predicting operative, trauma or post-discharge mortality were excluded.
3. Setting and target population: we focused on studies targeting over 1 month old children admitted in paediatric wards within resource-limited settings as specified by the World Bank¹⁴. Studies whose target population were children in HDU (High Dependency Unit) or ICU (Intensive Care Unit) were excluded because of limited availability of such facilities in LMIC. We also excluded studies whose target population included conditions not common in children, such as diabetes, cancer, chronic kidney disease, musculoskeletal disorders, etc. However, if a study focused on one of the common

1
2
3 childhood illnesses such as malaria, pneumonia, meningitis, anaemia, and
4
5 diarrhoea/dehydration³, then it was included.
6

- 7
8 4. Prognostic research studies: we included studies whose main objective was deriving a
9
10 predictive model(s) or scoring system(s). We excluded case-series, conference
11
12 proceedings, editorials, commentaries, expert views, case reports, reviews and studies
13
14 that mainly generate hypothesis such as explanatory studies¹⁵.
15
16
17 5. Predictors in the model: studies that reported multivariable model with at least 2
18
19 variables/predictors were included.
20
21
22 6. Full text and language: no language restrictions were made, we used Google Translate to
23
24 translate non-English language studies. We excluded studies that were not available in
25
26 full text.
27

28 *Search strategy of articles*

29
30
31 Based on CHARMS (Checklist for critical Appraisal and data extraction for systematic Reviews
32
33 of prediction Modelling Studies) checklist¹⁶, we identified seven core items (see supplementary
34
35 file 1 Table 1) specific to our study that guided the formulation of the eligibility criteria, review
36
37 aims, and the search strategy.
38

39
40 Where applicable, MeSH (Medical Subject Headlines) terms and keywords were used to identify
41
42 research papers developing predictive models relevant for this review (see supplementary file 1
43
44 Table 2). We conducted a search of articles in CINAHL (via EbscoHost), Google Scholar,
45
46 MEDLINE, and Web of Science published since inception to August 2019. To identify other
47
48 potentially eligible studies, we manually searched reference lists of the identified articles and
49
50 collated the final search results in EndNoteX7™ bibliography tool.
51
52
53
54
55
56
57

Screening of articles for inclusion

Prior to screening titles and abstracts, 2 reviewers (MO and LM) standardized the approach to be used in the process of screening and a sample of 30 articles were used to familiarize and train reviewers (MO, LM, and JA) on the process of screening of articles and data abstraction. Two reviewers (MO and LM) screened articles' titles and abstracts. Disagreements were resolved via discussion and the third reviewer (JA) adjudicated the final decision where necessary.

Data extraction from the included articles

For each of the study included, we used CHARMS guidelines to abstract the following data items; participant enrolment, study design, study population characteristics, location, sample size, number and selection of predictors, study dates, handling of continuous predictors, missing data, method of modelling (e.g. logistic regression, or survival), verification of model assumptions, internal validation methods (e.g. resampling techniques such as cross validations and bootstrapping, or random split of data); model presentation (e.g. full regression formula with coefficients, score chart, or nomogram); and model performance metrics including discrimination -area under the curve (AUC) accompanied with 95% CI (confidence intervals); calibration; classification metrics including specificity, sensitivity, positive, and negative predictive values. We further explored literature to determine if included models have been externally validated elsewhere. We treated each model separately for articles that developed multiple prognostic models. Data extracted from articles by the two reviewers (MO & LM) were compared and disagreements were resolved via discussion with the third reviewer (JA). Due to substantial heterogeneity that was observed after assessing studies included, we did not conduct a quantitative summary of the identified models.

Assessment of methodological rigor of the identified prognostic models

Based on PROBAST (Prediction study Risk Of Bias Assessment Tool) a Cochrane tool for assessing risk of bias (RoB) in predictive models,^{17 18} we assessed the RoB for each model in four domains: selection of the study participant, predictors domain (e.g. selection of the candidate predictors), statistical analysis domain (e.g. sample size, continuous predictors, missing data), and outcome domain. See Table 3 in supplementary file 1 for details. In each domain there were a set of signalling questions each with five possible answers: yes; probably yes; probably no; no; and no information. Any positive answer (yes, or probably yes) suggests low RoB. There were three possible outcomes per domain namely: low; high; or unclear RoB. Using these outcomes, we came up with an overall rating of RoB for each model. As recommended by PROBAST, a prognostic model was rated to be of “low RoB” if all four domains had an outcome of “low”. A prognostic model was rated “high RoB” if at least one domain had an outcome of “high”. Finally, a prognostic model was rated as “unclear RoB” if at least one domain had an outcome of “unclear” and the rest of the domains had an outcome of “low”.

Patient and public involvement

No patient or public involvement.

Results

Characteristics of the included studies

Our search strategy identified a total of 4054 unique articles, 3545 articles were excluded after review of titles and abstracts as they reported non-relevant topics. Full texts of 509 articles were assessed for eligibility, of which 15 primary studies reporting 21 developed models met the eligibility criteria (Figure 1). The eligible studies analysed data for patients who were below 15 years of age with median mortality being 6.7% (range 1.2% to 43.9%).^{19 20} While majority of the models were developed for general cases in paediatric wards (n=9), some were tailored for specific paediatric groups defined by common diagnoses such as febrile illness (n=1),²¹ malaria (n=2),^{22 23} pneumonia (n=4),^{19 24-26} malnutrition (n=2)^{27 28} and other infectious diseases (n=3) (see supplementary file 2).

Most of the included studies have been published post year 2000 (n = 20) except for one study²⁷ published in 1996. The latest data used in the models under review were from 2016 to 2017 by Rosman *et al.*²⁹ and the oldest data were utilized by Drimax *et al.*²⁷ from 1986 to 1988.

Five reports of the 15 included studies utilized data from at least two hospitals of which 3 studies^{21 22 26} were conducted in multiple countries including sub-Saharan Africa and Asian countries (Figure 2). Of the reviewed studies, most of the information we were abstracting were either not reported or were partially reported, an indication of non-adherence to the Transparent Reporting of a Multivariable Prognostic Model for Individual Prognosis or Diagnosis guidelines (TRIPOD).^{30 31}

Summary of issues in methodology of the reviewed models

Candidate predictors

There were 61 distinct predictors used in the final reported models with a median of 7 predictors in any one model. Initial selection of the independent candidate predictors was mostly based on univariable analyses except for three studies^{21 25 27} where the selection was based on literature reviews or clinical relevance. Backward stepwise selection method was used in 6 models in a multivariable analysis to determine final model predictors. Commonly included predictors in the final models included altered consciousness, malnutrition indicators, vital signs, and signs of respiratory distress (see Figure 3). Some models included predictors that were either not easy to obtain or required laboratory techniques. Of the 13 models that used continuous predictors, 8 models categorized these continuous predictors where a continuous scale would have been possible. Two out of 13 models applied other techniques such as fractional polynomial²¹ and restricted cubic splines²⁸ to determine the suitable functional form of the continuous predictors (see supplementary file 2).

Sample size, events per variable (EPV) and missing data

Sample size ranged from 168²⁹ to 50249³² with a median of 1307. The median EPV was 21(IQR 8.3 – 32.5) of which 7 models had less than 10 EPVs, suggestive of insufficient sample sizes which is prone to over-fitting. For instance, 60 deaths were reported in the dataset used to develop *PEDIA-Immediate* score in the study by Berkley *et al.* In reference to the rule that a study developing a predictive model should have a minimum of 10 events (deaths) for each independent candidate predictor in a predictive model,³³ a model with a maximum of 6

1
2
3 predictors should have been considered but 10 predictors were considered instead hence making
4
5 EPV to be 6.
6

7
8 Proportions of missing data was not always reported. Handling of missing data varied across the
9
10 reviewed studies as follows: 6 models did not report handling of missing data; 8 used complete
11
12 case analysis; 4 used multiple imputations by chained equations; and one study²⁸ used single
13
14 imputation.
15

16 17 Model development

18
19 Majority of the studies applied logistic regression, one study²¹ used Cox regression, one study²⁰
20
21 used Spiegelhalter/Knill-Jones method, and another study²³ used a machine learning technique
22
23 (classification and regression trees) in model development. Verification of model assumptions
24
25 was not reported in most of the studies. For instance, George *et al*²¹ despite utilizing Cox
26
27 regression to develop their model, did not report the verification of proportional hazard
28
29 assumption nor explore the possibility of competing risks as recommended³⁴. Other regression
30
31 assumptions e.g. multicollinearity was equally not reported. However, since backward
32
33 elimination method disregards redundant variables, we inferred the satisfaction of
34
35 multicollinearity assumption if this method was applied.³⁵ Five studies developed models using
36
37 data from different countries/centres but none of them clustered their analysis by source of data
38
39 in a multilevel model to account for heterogeneity. Ignoring clustering leads to a biased predictor
40
41 effect.³⁶
42
43
44
45
46
47

48 Model performance evaluation & presentation

49
50 Performance measures (both calibration and discrimination) were poorly reported in most of the
51
52 studies and in most cases (n=20) AUC for discrimination was reported. Performance of the
53
54 derived models was evaluated in 12 models using either split-sample, resampling methods, or
55
56
57

1
2
3 separate datasets. Except for the model derived by George *et al*,²¹ all other models did not report
4
5 both apparent discrimination (without any adjustment for optimism) and optimism-corrected
6
7 discrimination measures. Despite inadequate reporting of the models' performance, 16 models
8
9 reported AUCs ≥ 0.80 , an indication of promising models. Apart from the following exceptions;
10
11 *Lambarene Organ Dysfunction (LOD) score*,²² *Paediatric Early Death Index for Africa (PEDIA)*
12
13 *score*,²⁰ *Signs of Inflammation in Children that Kill (SICK) score*,³⁷ *Respiratory Index of Severity*
14
15 *in Children (RISC) score*,¹⁹ and *Modified Respiratory Index of Severity in Children (mRISC)*
16
17 *score*,²⁴ other prognostic models in this review have not been externally validated (by
18
19 independent investigators using diverse populations). Only 2 studies^{25 38} developing 4 models
20
21 provided a full model formula (both coefficients and intercept/baseline function) in their results
22
23 as recommended.^{30 31} While most of the models (n=17) were presented as simplified integer
24
25 scores, only a few were assigned weights according to the regression coefficients.
26
27
28
29
30

31 **Risk of bias (RoB)**

32
33
34 Based on the PROBAST tool, RoB was assessed in four domains; participants, predictors,
35
36 outcome, and analyses. Figure 4 summarizes the RoB assessment across all models included in
37
38 this review where the domain of outcome was deemed to be of low RoB in all models. The
39
40 domain of statistical analyses was the main area of concern where 19 out of 21 models did not
41
42 report comprehensive details of model development as expected to warrant a proper risk of bias
43
44 assessment using the 9 signalling questions under the analyses domain. As a result, these models
45
46 were judged to be of unclear RoB under this domain (see Figure 5). Details on how models were
47
48 scored against each of the PROBAST criterion (20 signalling questions) across the four domains
49
50 are provided in the supplementary file 3. In the overall judgement of RoB, 9 out of 21 models
51
52 were judged to be of high risk of bias because at least one out of four domains in these models
53
54
55
56
57

1
2
3 were rated as high RoB. The remaining models (12/21) were judged to be of unclear RoB on
4
5 account of being rated low and unclear RoB in the domains. No model was rated low RoB in all
6
7 four domains.
8
9

10 **Discussion**

11 **Summary of key findings**

12
13
14 We conducted a systematic review to identify scores predicting in-hospital mortality for
15
16 paediatrics in resource-limited countries. Fifteen studies that described the development of 21
17
18 prognostic models were identified. We describe characteristics of these studies as well as the
19
20 methodological quality of the included models by using agreed recent guidelines applicable to
21
22 predictive models. We have identified several important quality deficiencies such as inadequate
23
24 reporting and other methodological concerns, including poor handling of missing data,
25
26 automated selection of predictors, categorization of continuous predictors, inadequate EPV and
27
28 the poor presentation of the proposed model for use. As a result, no model was found to be of
29
30 good methodological quality and consequently judged to be potentially high or unclear risk of
31
32 bias in predictions (Figure 5).
33
34
35
36
37
38
39

40 Our findings suggest that predictive models fail to meet recently agreed methodological criteria
41
42 in various ways. Firstly, in this review we observed that univariable analysis was routinely used
43
44 in 18 out of 21 models in the selection of candidate predictors to be used in a multivariable
45
46 analysis. This strategy tends to leave out possibly important prognostic factors which might be
47
48 insignificant in a univariable analysis but turn out to be significant when combined with other
49
50 predictors.^{30 31} *A priori* selection of predictors using expert opinion, clinical intuition or literature
51
52 is recommended for this purpose,^{39 40} however only three studies in this review employed this
53
54 approach.^{21 25 27}
55
56
57

1
2
3 Small sample sizes in model development can lead to poor predictive performance, over-fitting,
4 and biased effect estimates. Prognostic models must have a minimum of ten events per candidate
5 independent predictor, as this is the accepted norm⁴¹⁻⁴³ and underpowered models arising from
6 inadequate events per variable (EPV) increases the possibility of spurious results.³³ In this
7 review, 7/21 models had inadequate sample sizes (EPV<10) and there was no information on
8 whether bootstrapping, which serves to reduce overfitting was used in these models.⁴⁴
9

10
11 Just like most of the epidemiological studies, missing data is a common problem which is solved
12 using multiple imputation or other appropriate approaches, but this was rarely the case in the
13 model development studies under this review. For instance, 8/21 models used Complete Case
14 Analysis (CCA), 4/21 used multiple imputation under the MAR (Missing at Random)
15 assumption, and 6/21 models did not report handling of missing data and therefore we assumed
16 CCA was used. Following Harrell's guidelines,⁴⁵ CCA should only be used if the percentage of
17 missingness is < 5% but the appropriateness of the CCA approach could not be ascertained as
18 most of the included studies failed to report the proportion of missing data per variable.
19

20
21 Inappropriate use of CCA results in use of only a small subset of the data which cannot be
22 regarded as a random sample from the target population unless data are MCAR (Missing
23 Completely At Random),⁴⁶ a mechanism which is rare in practice.⁴⁷ Consequently, there are
24 concerns about possible loss of precision in inferences and the potential biases of the estimated
25 parameters⁴⁸ in the models employing CCA. While Multiple Imputation by Chained Equations
26 (MICE) is the principled method of imputing missing data, implementing this method when the
27 data are not missing at random could result in biased model quantities.⁴⁹ As a result, sensitivity
28 analyses of the resultant imputations is recommended to investigate the departure from MAR
29 assumption.⁵⁰ However, this was not the case in the studies that performed imputations on their
30

52
53
54
55
56
57
58
59
60

1
2
3 data. Finally, handling of continuous predictors was also a concern in this review. Of the 13
4
5 models including continuous predictors, 8 models^{19 20 24-27 37 51} categorized continuous predictors
6
7 where a continuous scale would have been possible. While this approach is intuitive to most
8
9 researchers, its simplicity comes at a considerable cost of predictive performance.⁵² The resulting
10
11 prognostic models have been shown to have poor predictive accuracy because of the loss of
12
13 statistical power and information. It is recommended that the nature of continuous data should be
14
15 reserved or be handled by appropriate techniques e.g. flexible parametrizations such as fractional
16
17 polynomial, regression splines, or apply non-parametric techniques such as locally estimated
18
19 scatterplot smoothing (LOESS) functions.^{52 53} In this review, appropriate methods of
20
21 transforming continuous data was done by only 2 studies^{21 28} which applied restricted cubic
22
23 splines and fractional polynomial.
24
25
26
27

28 Sixteen models attained the discrimination metric of above 80%, an indicator of promising
29
30 models. However, given that the median mortality of the included studies was 6.7%, the
31
32 performance reported should be interpreted with caution on account of heavily imbalanced data
33
34 as a result of the rare nature of the outcome of interest. For instance, in a study with a mortality
35
36 rate of 5%, a model predicting no deaths could easily attain 95% accuracy which could be
37
38 potentially misleading^{34 54}. Therefore, authors should report additional measures of model
39
40 performance such as model specificity, sensitivity, accuracy, positive and negative predictive
41
42 values for models to be contextualized appropriately.

Comparison with Other Studies

Methods used to assess quality measures of the included models in the current study have been applied previously to critically evaluate the quality of predictive models in other specialties.⁵⁵⁻⁵⁷ Just like the findings of this review, other previous reviews^{9 58-60} describing the development of prognostic models highlighted many flaws including inappropriate statistical analyses, poor reporting of key methodological information necessary for model validation, and lack of external validations in general. Detailed and transparent reporting of the methods used in model development is one of the core principles of integrity in research because this is the only way the research community is able to evaluate study findings, and the assessment of risk of bias.⁶¹ Incomplete reporting of clinical models limits future studies on prognostic research from building on the information of already existing models. This has been marked as an important source of wasted research efforts.⁶² For example, external validation of prognostic models requires a full model formula to enable direct estimation of survival probabilities.³¹ However, this was presented in only 4 models. Five models^{19 20 22 24 37} that were reported to have undergone external validation did not report full model formula as required. It is therefore not clear whether authors of these external validation studies applied model coefficients to the external datasets, or they estimated new model coefficients (essentially model redevelopment). Thus, this review highlights the need for researchers to adhere to the TRIPOD guidelines that were created to help authors of prognostic models write complete and transparent reports. Of note, the quality of clinical predictive models does not appear to have improved over time as previous reviews from 1996,⁶³ 1997,⁶⁴ 2001,⁶⁵ 2005,⁶⁶ 2011,⁸ 2012,⁶⁷ 2016,^{68 69} 2017,⁷⁰ to 2019⁷¹ have consistently identified suboptimal methodologies in the development of the score/predictive models especially in the domain of analysis. Poorly derived models may result

1
2
3 in overoptimistic results and misleading performances. Presumably there are reasons why many
4 prognostic models are of poor quality, including pressure to publish new predictive model
5
6 regardless of the clinical value of the resultant model⁷², and inadequate biostatistical support to
7
8 investigators. As observed by one of the reviewers of this study, some of the issues identified in
9
10 this review such as absence of the details on the model development process can be corrected
11
12 during the review and the editorial process by the journals publishing the work. There is
13
14 therefore a role for editorial process for promoting best practices and recommendations of
15
16 developing predictive models stated in the TRIPOD statement and ensuring compliance by
17
18 authors as part of checklist for submission.
19
20
21
22
23

24 **Implications of this study**

25
26
27 Prognostic model development pipeline include development, validation (internal and external),
28
29 impact assessment and implementation. Most of the included models are still in the first step of
30
31 the pipeline. This suggests that researchers focus more on deriving new models, often using
32
33 similar prognostic factors, rather than validating and improving existing prognostic models. This
34
35 leaves healthcare policy makers with doubts as to which model to recommend in their setting. It
36
37 is now time to move the prognostic research to the next step (external validation). Large patient-
38
39 level datasets such as that of the Clinical Information Network (CIN)³ which has been collected
40
41 over time from a number of referral hospitals now exist in Kenya and it has been used to answer
42
43 a number of salient clinical questions relevant across a range of resource-limited setting⁷³⁻⁷⁵.
44
45
46
47

48 Future studies on prognostic research should leverage such datasets to externally validate
49
50 competing models identified in this review for comparative performances as recommended by
51
52 Collins *et al*,⁷⁶ and if necessary, predictive performance of such models should be improved by
53
54 addition of new prognostic factors. We also noted that most of the included models simplified
55
56
57

1
2
3 the original predictor coefficients by rounding them to a nearest integer. This practice has an
4
5 implication on model performance during external validation due to loss in predictive accuracy
6
7 arising from rounding coefficients to nearest integers.⁴⁷
8
9

10 We now provide guidance on methodological concerns about the candidate predictors as noted in
11
12 this review. While considering potential candidate predictors to include in the prediction model,
13
14 researchers should focus on the predictors that will be available at the time the prediction is
15
16 made. We acknowledge that some predictors obtained from invasive procedures e.g. C-reactive
17
18 protein, blood gas analyses, blood or cerebrospinal fluid culture, etc might have a higher
19
20 predictive value for mortality compared to predictors derived from subjective clinical
21
22 assessments, however in resource-limited settings results of such laboratory tests typically take
23
24 days to be reported or resources might not available to perform such tests in many hospitals.
25
26 Consequently, models utilising such variables might not be useful to clinicians to make a
27
28 decision at typical emergency departments in LMIC. Screening of model candidate predictors
29
30 based on the bivariate associations whereby predictors are selected if they meet some *p*-value
31
32 threshold (commonly 0.05) have been strongly discouraged previously^{77 78}. Categorising
33
34 continuous model predictors is a common practice by researchers however this practice discards
35
36 a lot of information and its assumptions are rarely clinically plausible.³⁴ Finally, there is a risk of
37
38 overfitting if the model includes more predictors than the dataset can support. The ratio of the
39
40 events (deaths) to the number of independent candidate predictors have been discussed
41
42 extensively in methodological papers elsewhere^{79 80} and it has been recommended that ratio of
43
44 the EPV should be at least 10.

Strengths and limitations

To our knowledge, this is the first systematic review identifying prognostic models and scoring systems predicting in-hospital all-cause paediatric mortality in low-and-middle income settings. Our robust search strategy yielded a number of potentially eligible studies, hence it is unlikely that any potentially eligible study was not included. The quality of included models was assessed based on recent reporting standards and applied to the identified studies. For instance, if no mention was made of internal validation or even verification of the model assumptions, we could determine whether these crucial steps of model development were carried out or not. Thus, models that could have been otherwise rated as low risk of bias were rated as either unclear or high risk of bias in each domain. The PROBAST's analysis domain has most (9 out of 20) of the signalling questions and any given model in this domain had much higher chance to be defined as high risk as long as there was one negative (no or probably no) answer. This strict criterion led to all models being classified as either unclear or high risk of bias and therefore metanalysis was not performed. We acknowledge that if we somewhat relaxed this decision rule, our conclusion could change. Despite this, we still hold that authors should adhere to guidelines of transparent and complete reporting of any proposed prognostic model to facilitate its external validation and subsequent application in practice. Finally, we used Google Translate to interpret a study by Bitwe et al⁵¹ from French to English. It is possible that some statistical terminologies were not rendered correctly, or some model characteristics were lost in translation.

Conclusion

Rigorously developed and robustly validated promising predictive models have the potential for improving child survival in resource-limited countries. This review identified models predicting in-hospital mortality for paediatrics. However, none of them is of good quality. Our research

1
2
3 highlights the need to improve on the identified quality deficiencies when developing prognostic
4 models in the future by adhering to existing generally accepted standardized methodological
5 criteria. Majority of the derived models have not been externally validated as required.
6
7

8
9
10 Inadequate reporting observed in the included models hinders rigorous external validation by
11 other researchers in addition to undermining their application. Rather than developing new
12 prognostic models, researchers should carry out comprehensive joint external validation of the
13 identified models using large datasets ideally collected over extended time periods and different
14 locations. This will allow model comparisons and adaptation of the competing models, if
15 necessary, to ascertain their generalizability.

Table 1: Systematic review framework as recommended by CHARMS checklist

Item	Criteria
Prognostic or diagnostic model	Prognostic model predicting in-hospital mortality.
Scope	Prognostic models to inform clinicians about the risk of deterioration or death.
Type of prediction models	Prognostic models with and/or without external validation.
Prediction target population	Children aged > 1 month to 15 years admitted in pediatric wards in developing countries
Outcome of interest	All-cause in-hospital mortality.
Prediction period	Any
Intended moment to apply the prediction tool	Prognostic model to be used in primary prevention to assess risk of deterioration and thus guide prevention/treatment.

KEY:

CHARMS= Checklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies

Table 2: Search terms for prognostic models

Search ID	Sub-heading	Search Terms
S4	Children	paediatric* OR pediatric* OR (MH "Pediatrics+") OR child*
S3	Hospital based	(MH "Hospitals+") OR hospital*
S2	Low-income countries	(MH "Developing Countries+") OR (MH "Africa+") OR TI ("low income" OR "low and middle income" OR "LMIC" OR "LIC" OR "limited resource*" OR "poor resource*" OR "resource* poor" OR ("developing countries") OR ("developing nations") OR ("third world") OR "resource-constrained" OR ("global south"))
S1	Predictive models	prognos* OR (MH "prognosis") OR (Predict* AND (Outcome* OR Risk* OR Model* OR Mortality OR Index OR Rule* OR decision* OR scor*)) OR "risk score" OR "scor* system" OR "logistic model*" OR "risk prediction" OR "risk calculation" OR "risk assessment" OR "c statistic" OR discrimination OR calibration OR AUC OR "area under the curve" OR "area under the receiver operator characteristic curve"

Table 3: List of domains and signaling questions used for assessment of risk of bias according to the PROBAST tool.

Domain	Signalling question
Participants selection	Were appropriate data sources used, e.g., cohort, RCT, or nested case–control study data?
	Were all inclusions and exclusions of participants appropriate?
Predictors	Were predictors defined and assessed in a similar way for all participants?
	Were predictor assessments made without knowledge of outcome data?
	Are all predictors available at the time the model is intended to be used?
Outcome	Was the outcome determined appropriately?
	Was a prespecified or standard outcome definition used?
	Were predictors excluded from the outcome definition?
	Was the outcome defined and determined in a similar way for all participants?
	Was the outcome determined without knowledge of predictor information?
	Was the time interval between predictor assessment and outcome determination appropriate?
Analysis	Were there a reasonable number of participants with the outcome?
	Were continuous and categorical predictors handled appropriately?
	Were all enrolled participants included in the analysis?
	Were participants with missing data handled appropriately?
	Was selection of predictors based on univariable analysis avoided?
	Were complexities in the data (e.g., censoring, competing risks, sampling of control participants) accounted for appropriately?
	Were relevant model performance measures evaluated appropriately?
	Were model overfitting, underfitting, and optimism in model performance accounted for?
	Do predictors and their assigned weights in the final model correspond to the results from the reported multivariable analysis?

Reporting checklist for systematic review and meta-analysis.

Based on the PRISMA guidelines.

Instructions to authors

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the PRISMA reporting guidelines, and cite them as:

Moher D, Liberati A, Tetzlaff J, Altman DG, The PRISMA Group. Preferred Reporting Items for Systematic Reviews and Meta-Analyses: The PRISMA Statement

	Reporting Item	Page Number
Title		
	#1 Identify the report as a systematic review, meta-analysis, or both.	1

Abstract

1	Structured	#2	Provide a structured summary including, as applicable:	2
2				
3	summary		background; objectives; data sources; study eligibility criteria,	
4			participants, and interventions; study appraisal and synthesis	
5			methods; results; limitations; conclusions and implications of key	
6			findings; systematic review registration number	
7				
8				
9				
10				
11				
12				
13	Introduction			
14				
15				
16	Rationale	#3	Describe the rationale for the review in the context of what is	3
17			already known.	
18				
19				
20				
21				
22	Objectives	#4	Provide an explicit statement of questions being addressed with	3
23			reference to participants, interventions, comparisons, outcomes,	
24			and study design (PICOS).	
25				
26				
27				
28				
29	Methods			
30				
31				
32	Protocol and	#5	Indicate if a review protocol exists, if and where it can be	4
33	registration		accessed (e.g., Web address) and, if available, provide	
34			registration information including the registration number.	
35				
36

38				
39				
40	Eligibility criteria	#6	Specify study characteristics (e.g., PICOS, length of follow-up)	4
41			and report characteristics (e.g., years considered, language,	
42			publication status) used as criteria for eligibility, giving rational	
43				
44				
45				
46				
47				
48	Information	#7	Describe all information sources in the search (e.g., databases	N/A
49	sources		with dates of coverage, contact with study authors to identify	
50			additional studies) and date last searched.	
51				
52				
53				
54				
55	Search	#8	Present full electronic search strategy for at least one database,	5
56			including any limits used, such that it could be repeated.	
57				
58				
59				
60				

1	Study selection	#9	State the process for selecting studies (i.e., for screening, for	6
2			determining eligibility, for inclusion in the systematic review, and,	
3			if applicable, for inclusion in the meta-analysis).	
4				
5				
6				
7				
8	Data collection	#10	Describe the method of data extraction from reports (e.g., piloted	6
9	process		forms, independently by two reviewers) and any processes for	
10			obtaining and confirming data from investigators.	
11				
12				
13				
14				
15				
16	Data items	#11	List and define all variables for which data were sought (e.g.,	6
17			PICOS, funding sources), and any assumptions and	
18			simplifications made.	
19				
20				
21				
22				
23				
24	Risk of bias in	#12	Describe methods used for assessing risk of bias in individual	7
25	individual studies		studies (including specification of whether this was done at the	
26			study or outcome level, or both), and how this information is to	
27			be used in any data synthesis.	
28				
29				
30				
31				
32				
33				
34	Summary	#13	State the principal summary measures (e.g., risk ratio, difference	N/A
35	measures		in means).	
36				
37				
38				
39	Planned methods	#14	Describe the methods of handling data and combining results of	N/A
40	of analysis		studies, if done, including measures of consistency (e.g., I ²) for	
41			each meta-analysis.	
42				
43				
44				
45				
46				
47	Risk of bias	#15	Specify any assessment of risk of bias that may affect the	7
48	across studies		cumulative evidence (e.g., publication bias, selective reporting	
49			within studies).	
50				
51				
52				
53				
54	Additional	#16	Describe methods of additional analyses (e.g., sensitivity or	N/A
55	analyses		subgroup analyses, meta-regression), if done, indicating which	
56				
57				
58				
59				
60				

were pre-specified.

Results

Study selection	#17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram .	8
Study characteristics	#18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citation.	8
Risk of bias within studies	#19	Present data on risk of bias of each study and, if available, any outcome-level assessment (see Item 12).	11
Results of individual studies	#20	For all outcomes considered (benefits and harms), present, for each study: (a) simple summary data for each intervention group and (b) effect estimates and confidence intervals, ideally with a forest plot.	N/A
Synthesis of results	#21	Present the main results of the review. If meta-analyses are done, include for each, confidence intervals and measures of consistency.	N/A
Risk of bias across studies	#22	Present results of any assessment of risk of bias across studies (see Item 15).	11
Additional analysis	#23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression [see Item 16]).	N/A

Discussion

1	Summary of	#24	Summarize the main findings, including the strength of evidence	12
2				
3	Evidence		for each main outcome; consider their relevance to key groups	
4				
5			(e.g., health care providers, users, and policy makers	
6				
7				
8				
9	Limitations	#25	Discuss limitations at study and outcome level (e.g., risk of bias),	15
10				
11			and at review level (e.g., incomplete retrieval of identified	
12				
13			research, reporting bias).	
14				
15				
16	Conclusions	#26	Provide a general interpretation of the results in the context of	16
17				
18			other evidence, and implications for future research.	
19				
20				
21				
22	Funding			
23				
24				
25	Funding	#27	Describe sources of funding or other support (e.g., supply of	17
26				
27			data) for the systematic review; role of funders for the systematic	
28				
29			review.
