

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<u>http://bmjopen.bmj.com</u>).

If you have any questions on BMJ Open's open peer review process please email <u>info.bmjopen@bmj.com</u>

## 26 Abstract

Introduction: Delirium is one of the most common conditions diagnosed in hospitalised older people
and is associated with numerous adverse outcomes, yet there are no proven pharmacological
treatments. Recent research has identified cerebral glucose hypometabolism as a pathophysiological
mechanism offering a therapeutic target in delirium. Insulin, delivered via the intranasal route, acts
directly on the central nervous system and has been shown to enhance cerebral metabolism and
improve cognition in patients with mild cognitive impairment and dementia. This trial will determine
whether intranasal insulin can reduce the duration of delirium in older hospitalised patients.

Methods and analysis: This is a prospective randomised, placebo-controlled, double blind study with 6 months follow up. One hundred patients aged 65 years or older presenting to hospital with delirium admitted under Geriatric Medicine will be recruited. Participants will be randomised to intranasal insulin detemir or placebo administered twice daily until delirium resolves, defined as Confusion Assessment Method (CAM) negative for two days, or discharge from hospital. The primary outcome measure will be duration of delirium using the CAM. Secondary outcome measures will include length of hospital stay, severity of delirium, adherence to treatment, hospital complications, new admission to nursing home, mortality, use of antipsychotic medications during hospital stay and cognitive and physical function at 6-months post-discharge.

Ethics and dissemination: This trial has been approved by the South Eastern Sydney Human Research
and Ethics Committee. Dissemination plans include submission to a peer-reviewed journal for
publication and presentation at scientific conferences.

46 Trial registration: ACTRN12618000318280

52

53

54

The study design is pragmatic, inclusive and representative of real-world older hospitalised
 patients who are often omitted from research due to multimorbidity.

• The results will add valuable insights into the neural mechanisms leading to delirium.

• Patients in this study will be followed up trained assessors daily for up to one-week postdischarge, however, assessment after one week is beyond the allocated resources for this

# 55 Background

trial.

56 Delirium is common, with figures reporting 10-35% of older people are delirious on admission to 57 hospital (prevalent delirium) and up to another 29% will become delirious during their admission (incident delirium) (1). It is characterised by sudden and fluctuating disturbances in cognition, 58 59 attention and awareness (2). The sequelae of delirium are manifold and extend beyond the acute 60 hospitalisation; increased mortality, new cognitive impairment, accelerated dementia, loss of 61 independence and increased admission to nursing home(3, 4). In older patients, delirium is 62 independently associated with a two-fold increase in mortality at 12 months (5). Longer duration 63 and increased severity of delirium predict poorer outcomes in older patients (6).

54 Studies suggest that only 30% of incident delirium is potentially preventable with non-pharmacological 55 multimodal intervention (7). Current management focuses on identifying and treating the underlying 66 cause of delirium combined with non-pharmacological interventions to provide an optimal 67 environment for brain recovery and reduce the risk of potentially avoidable complications such as falls 68 and pressure injuries.

69 Pharmacological management is focused on symptomatic control with antipsychotics. However,
 70 evidence does not support the use of antipsychotics for delirium and a recent randomised controlled
 71 trial demonstrated worsening symptoms and increased mortality (8, 9). At this point in time there are
 72 no proven pharmacological interventions to prevent or manage delirium.

#### **BMJ** Open

Delirium pathophysiology is poorly understood, although several hypotheses exist. These include neuroinflammation (10), neurotransmitter dysregulation (11), neuroendocrine dysregulation (12) and neural network dysconnectivity (13). As delirium is a complex and heterogeneous disorder, it is likely that several of these mechanisms may contribute to the development of delirium with varying effect depending on pre-existing patient vulnerabilities and the aetiology of the acute precipitant (14). However, regardless of the underlying cause, delirium presents in a recognisable and stereotyped manner (phenotypically hypoactive, hyperactive and mixed) and the hypothesis that a "final common pathway" may exist should not be disregarded.

Research has identified altered cerebral perfusion and metabolism as a feature of delirium. Delirious patients have higher cerebrospinal fluid (CSF) lactate and lower neuron-specific enolase suggesting suppressed aerobic metabolism during an episode of delirium (15, 16). Two studies have demonstrated cerebral glucose hypometabolism during delirium using fluorodeoxyglucose positron emission tomography (FDG-PET) (17, 18). Haggstrom et al have demonstrated a correlation between posterior cingulate cortex hypometabolism and attention as well as evidence of improved cortical glucose metabolism with resolution of delirium (17). Neuroimaging studies using a variety of modalities have demonstrated reduced cerebral perfusion, decreased cerebral oxygenation and abnormal cerebral autoregulation during an episode of delirium (19, 20). As cerebral blood flow and metabolism are closely coupled and considered to reflect synaptic activity(21), correction of perfusion and metabolism abnormalities may improve clinical outcomes in delirium. 

92 It is now well established that the brain is an insulin sensitive organ; insulin receptors are widely
93 expressed in the brain, with greatest saturation in the corticolimbic structures (22). Insulin enhances
94 learning and memory by modulating neuronal growth, metabolism, plasticity and cholinergic function
95 (22, 23).

96 The role of glucose metabolism in the pathogenesis of neurodegenerative disease is a growing area of 97 research (24). Mild Cognitive Impairment (MCI) and Alzheimer's Dementia (AD) have been

98 characterised as states of brain-specific insulin resistance and deficiency sometimes called "type 3 99 diabetes" (25). Patients with early stage AD demonstrate pronounced insulin and insulin-like growth 100 factor deficiency and resistance which progress with severity of neurodegeneration (22). 101 Administration of intravenous (IV) insulin while maintaining fasting serum glucose levels improves 102 memory in patients with Alzheimer's Disease (26). However, therapeutic administration of IV insulin 103 is not feasible or safe due to the substantial risk of systemic hypoglycaemia.

The intranasal route of delivery provides a non-invasive and safe means of transporting insulin to the brain. A recent systematic review identified seven studies (total, N =293) examining the effect of intranasal insulin on MCI or AD, of which six demonstrated significant improvements in verbal memory (27). Positive outcomes in functional status were also observed (28-30). Improvements in attention, visuospatial memory and executive function have also been demonstrated in other populations (31-33).

110 One pilot trial has assessed the effect of intranasal insulin on delirium prevention in a cohort of 21 111 older cardiothoracic surgical patients (34). The incidence of postoperative delirium was lower in the 112 intranasal group (18% vs 40%) although the result was not statistically significant, likely due to the 113 small sample size. No serious adverse events were reported (35).

114 Given that intranasal insulin improves cognition as well as cerebral perfusion and metabolism, this
 <sup>13</sup> 115 trial will investigate its potential role in treatment of delirium.

116 This randomised controlled trial will evaluate whether intranasal insulin, compared to placebo, can

117 reduce the duration of delirium in older patients admitted under Geriatric Medicine.

## 118 Methods

119 Design

This is a single site, randomised, double-blind, placebo-controlled trial of 100 older people diagnosed
with delirium on admission to hospital (prevalent delirium). Figure 1 gives an overview of study
design.

This research will be conducted in accordance with the Declaration of Helsinki. The trial methods, protocol and consent procedures were approved by the South Eastern Sydney Human Research and Ethics Committee (HREC 16\_320). As required by the New South Wales Guardianship act 1987 (part 5), New South Wales Civil and Administrative Tribunal, approval to conduct this clinical trial has also been obtained (case number 2017/00204946). The trial was registered in the Australian and New Zealand Clinical Trial Registry on 5 March 2018 (ACTRN12618000318280).

ies

#### 130 Population

The study population will comprise older people admitted under a Geriatrician at a large tertiary hospital in metropolitan Sydney, Australia. Potential participants must be a) diagnosed with prevalent delirium, b) receiving inpatient care on the Geriatric Medicine Wards, c) age > 64 years, d) have a consenting "person responsible" and e) be enrolled in the trial within 24 hours of admission to hospital. People with known cognitive impairment and dementia will be included. Exclusion criteria include a) people who are haemodynamically unstable, b) have a predicted life expectancy of less than seven days as judged by the admitting geriatrician, c) have an allergy to insulin detemir formulation or d) a structural abnormality precluding the use of the nasal drug delivery device. People will also be excluded if consent is not obtained or they were previously

1 2

### 143 Screening and Evaluation of delirium

Within the emergency department or on transfer to the Geriatric Medicine Ward, all patients age
>64 years will be screened by nursing staff for delirium using the Confusion Assessment Method
(CAM) (36, 37). Patients with delirium diagnosed by a Geriatrician or Advanced Trainee in Geriatric
Medicine using the Diagnostic and Statistical Manual of Mental Disorders Fifth Edition criteria (DSM
V) will be considered for the trial (38).

149Study team members will use the CAM to conduct daily delirium assessments between 12-2pm. All150members of the study team will undergo formal training using the CAM. Bedside assessment will be151supplemented by review of the medical records and collateral history from the patient's carer or152ward staff where appropriate. The presence of delirium will be documented using the long form153CAM (36). Delirium severity will be assessed using the Delirium Index (DI) (39). Delirium clinical154subtype will be assessed using the abbreviated version of the Delirium Motor Subtyping Scale155(DMSS-4) (40).

156 Interrater reliability using the CAM and DI will be assessed using Cohen's kappa coefficient based on
157 twenty patient reviews (41).

159 Consent

158

160 Consent will involve conversations regarding the study risks, benefits and burdens between the
 161 researchers, patient and the "person responsible" (substitute decision maker according to the New

1 2		
- 3 4	162	South Wales Guardianship Act 1987). To avoid a delay in initiation of the intervention, where a
5 6	163	person responsible is unable to attend the hospital to sign the consent, an initial verbal consent may
7 8 9	164	be granted (by phone) and written consent obtained as soon as possible.
10 11 12	165	Consent to remain in the trial will be obtained from the patient if capacity returns. Should the
12 13 14	166	patient decline further involvement in the trial the researcher will ask the patient for consent to use
15 16 17	167	trial data up until the time of withdrawal in the final analysis.
18 19	168	Consent will also be obtained for the collection and study of patient blood specimens.
20 21 22 23	169	
24 25 26	170	Assessment over the study period
27 28	171	Table 1 highlights the measures to be undertaken at each pre-determined time point.
29 30 31	172	Measurements will be taken daily while receiving the intervention. Patient assessment will also
32 33 34	173	occur at discharge from hospital and 6 months post discharge.
34 35 36	174	In addition to routine blood tests, 20millilitres of blood will be taken from each patient and stored
37 38	175	for later analysis, including the effect of Apolipoprotein E4 (APOE4) status on study outcomes.
39 40	176	Specimens will be frozen and stored at -80 degrees Celsius in the University of New South Wales
41 42 43	177	Lowy Biorepository.
44 45 46	178	
47 48 49 50	179	Randomisation and blinding
51 52	180	Permutated block randomisation will be conducted with a block size of 4 and 25 blocks using a
53 54	181	computer-generated algorithm. An independent clinical trials pharmacist will create the
55 56 57	182	randomisation schedule which will be provided to the clinical trials pharmacy staff responsible for
57 58 59	183	production and dispensing of the medication. Each vial of insulin or placebo will be labelled with a
60	184	sequentially allocated randomisation number, which will become that patient's study number.

Participants, research and ward staff will be blinded to treatment allocation. 

Intervention Patients will receive 20 international units (IU) of long-acting insulin (detemir) or a placebo of normal saline intranasally twice daily at 8am and 8pm via a commercially available drug delivery device (ViaNase delivery device, Kurve Technology, Bothell, Washington). This device has been used successfully in previous trials of intranasal insulin in cognitive impairment (29, 30). The device will release 20IU insulin detemir or placebo intranasally via a small nose piece over a 40 second period. Patients will receive 20 seconds per nostril twice daily and during administration be instructed to breath normally through the nose. Following intranasal administration, insulin enters the brain either through direct entry via the cribriform plate and the olfactory nerves or via specific receptors in the blood-brain barrier or a combination of the two (42). In 15-30 minutes, insulin peptides are detected within the cerebral cortex and hippocampus (43). Compared to the subcutaneous route, intranasal administration of insulin demonstrates an approximately 2000-fold increase in the AUC<sub>brain:plasma</sub> ratio, meaning at similar doses the intranasal route reaches comparable or increased brain insulin concentration but substantially lower plasma concentration (44). The total daily dose of 40IU of insulin detemir is based on research by Claxton et. al demonstrating safety and efficacy in older patients with Alzheimer's dementia. In this trial, 60 patients with mild cognitive impairment or mild-to-moderate AD received either placebo, 20IU of insulin detemir, or 40IU of insulin detemir intranasally for 21 days. Participants receiving 40IU of insulin detemir demonstrated significant improvements in verbal and visuospatial working memory. No statistically significant effect was found in the 20IU detemir group. No treatment-related severe adverse events were reported (45).

1 2		
2 3 4	209	Pre-prepared, spare vials and in-use devices will be stored between 2-8 degrees Celsius in the ward
5 6 7	210	medication fridge.
8 9	211	The medication will be administered by ward registered nurses specifically trained for the trial.
10 11	212	Insulin is considered a "schedule 4" drug meaning two nurses must check the prescription, patient
12 13 14	213	identity and be present for drug administration. Nurses will record challenges regarding
15 16	214	administration of the intervention, including partially received or omitted doses, in the electronic
17 18 19	215	patient record which will be reviewed by trial staff daily.
20 21	216	The intervention will cease following two consecutive CAM negative days.
22 23	217	Cessation of treatment with the study intervention will also occur if:
24 25	218	The patient is discharged from the hospital
26 27 28	219	Patient or treating clinician requests discontinuation
29 30	220	Unacceptable side effects from study medications (defined by National Cancer Institute
31 32	221	Common Criteria for Adverse Events; Common Terminology Criteria for Adverse Events
33 34	222	version 4.0)
35 36 37	223	• Participants who in the opinion of the investigator are not well enough to continue in the
38 39	224	study
40 41	225	Adverse events related to the study medicine are unacceptable to the participant/carer or
42 43	226	clinician in charge e.g. symptomatic or severe hypoglycaemia (blood sugar level <3.0mmol/L)
44 45 46	227	• Treatment is deemed ineffective, defined as no improvement in delirium index over 7 days.
47 48 49	228	Patients withdrawn from the study will be included in statistical analysis on an intention-to-treat
50 51	229	basis.
52 53 54 55 56 57 58 59 60	230	

### 231 Safety

Studies have demonstrated that less than 3% of intranasally-delivered insulin is detectable in the
serum and as a result intranasal insulin has a negligible risk of hypoglycaemia (27, 46). A systematic
review on the safety of intranasal insulin included 38 studies (N=1092) and found no cases of
hypoglycaemia or severe adverse events (47). The most commonly reported side effects were
transient and local to the nasal area including nasal tingling and burning, less commonly rhinitis and
nasal bleeding occurred.

Although the risk of hypoglycaemia is largely theoretical, blood glucose levels will be measured at
baseline and four times daily during the study intervention (07:00, 13:00, 19:00, 22:00). As adequate
and uninterrupted sleep is a core principle in delirium management and disturbed sleep can
precipitate or exacerbate delirium, blood glucose levels will not be taken overnight.

Adverse events will be assessed daily through participant interview supplemented by review of the electronic medical record. Serious adverse events as defined by the International Conference on Harmonisation Guidelines for Good Clinical Practice will be reported in accordance with local ethics requirements. An independent data and safety monitoring board (DSMB) will oversee the study and meet after each twenty patients. Serious adverse events will be discussed with the lead investigator immediately and reported to the Human Research Ethics Committee (HREC) and trial DSMB within 248 24 hours.

Delirium is associated with a high in-hospital mortality rate, previously demonstrated to reach 35% in an older population (48). As such, a key role of DSMB will be to review all deaths and serious adverse events in detail to determine if the adverse event was in keeping with the natural history of the illness or could be attributed to the study intervention (49). Should concerns arise regarding patient safety the DSMB may request to unblind for decision making purposes.

#### **BMJ** Open

There are two main scenarios which could prompt DSMB to request termination of the study. Firstly, if there are a significant number of serious adverse events possibly attributed to the intervention leading to patient safety concerns and secondly, significant benefit from the intervention. Should termination of the trial be requested, researchers would be unblinded and data analysis would occur. The HREC and participants would be informed the trial was stopped and reasons for termination given.

#### Outcomes

The primary and secondary outcomes are outlined in table 1. The primary outcome will be duration of delirium in days. Delirium assessment will be conducted daily from enrolment until delirium resolution, defined as two consecutive days (48hours) CAM negative. Patients discharged with delirium will be followed up daily for up to one week to assess for delirium resolution. Secondary outcomes will determine if intranasal insulin compared to placebo decreases acute length of hospital stay, reduces severity of delirium, reduces hospital complications, reduces new admission to nursing home, decreases mortality and decreases use of antipsychotic medications during an inpatient stay. Patients will be followed up at 6 months post-discharge to assess if intranasal insulin reduces mortality and preserves cognition and function. Adherence to the intervention will be measured by percentage of doses successfully administered.

#### Sample size

Power analysis (with 5% significance and 80% power) was performed using published data which shows the mean duration of delirium clustered at approximately 8 days in Geriatric medicine ward populations(50, 51). Power calculation shows reducing delirium duration by two days (from 8 days to

6 days) requires 36 in each arm for a total of 72 patients. Allowing for a 30% dropout rate, a total of 100 participants will be sought.

#### **Statistical Analysis**

Statistical analysis will be conducted using IBM SPSS Statistics software. An intention-to-treat approach will be adopted for all analyses and statistical significance assumed at the level of 5% (P<0.05). Baseline characteristics will be reported for the overall population and separately for each group.

The primary outcome, duration of delirium measured in days, will be analysed first with a Mann Whitney U test which has high statistical power (52) and then using survival analysis Cox proportional hazard method including dementia, nursing home status, severity of disease and comorbidity as covariates. Sensitivity analysis will be conducted using normality-improving data transformations or Gamma regression with a log link according to the distribution of the primary outcome. For the major secondary outcome, trajectory of delirium severity measured by the delirium index over time, a generalised linear mixed model will be used. Binary outcomes like mortality (in-hospital and at six months) and institutionalisation will be evaluated using a modified Poisson regression (53). A linear regression will assess possible preservation of function, measured by Barthel index (54) and modified Instrumental Activities of Daily Living (55), and for all other linear secondary outcomes. Bootstrapping will be applied if the models fail to satisfy the normality assumptions. For length of hospital stay, a log-linear or gamma regression with a log link will be implemented. The number of hospital complications and the use of antipsychotics during hospitalization will be reported. Subgroup analysis stratifying by age, sex, dementia and APOE status will be conducted.

#### 301 Data Management

302 Data will be collected by trained researchers and stored on a password protected database. One
 303 researcher will be responsible for data entry while another member of the study team will monitor
 304 the accuracy of data by cross-checking a random 10% sample of subjects.

Paper files of individual records will be stored in a locked cabinet in a secure location accessible to authorised members of the study team only. Electronic data will be entered in a de-identified format and stored on a password-protected secure server. The complete data set will be stored on the University of New South Wales Data Archive and will be made available at the completion of the trial

309 on reasonable request.

310

#### 311 Patient and public involvement

A public representative approved trial concept, design and consent procedures as part of the
application to New South Wales Civil and Administrative Tribunal. Results of the trial will be
published in biomedical journals and presented at international scientific conferences. Social media
platforms will be used to inform the general public about the results. Authorship on publications
related to this study will follow standard eligibility guidelines ensuring significant contribution.

# 318 Discussion

317

Delirium is a debilitating condition commonly affecting older people in hospital and for which there are no registered treatments. It has been consistently demonstrated that longer duration of delirium predicts worse outcomes, including higher mortality and new admission to residential aged care facility (6, 56). Although the pathophysiological mechanisms are incompletely understood, it is probable that an episode of delirium causes irreversible neuronal damage leading to sustained

324 cognitive and functional impairment (57), with prolonged delirium exposure leading to greater325 cerebral damage.

To date, there are no trials assessing intranasal insulin as a treatment for delirium, however, it could improve cognitive and clinical outcomes for delirious patients via a variety of mechanisms. Intranasal insulin increases cerebral perfusion (32, 58-60) and increases or maintains cerebral glucose metabolism on FDG-PET (61, 62). In young healthy adults and patients with type II diabetes mellitus, intranasal insulin enhances functional connectivity within the default mode network, an important centre for higher cognitive processes in which delirious patients demonstrate dysconnectivity (13, 63, 64). The hypothalamic-pituitary-adrenal (HPA) axis is also insulin responsive and following administration of intranasal insulin healthy populations demonstrate diminished saliva and plasma cortisol (31, 65). As aberrant HPA axis activity is hypothesised to contribute to delirium pathophysiology, modification of this pathway may also lead to improved outcomes (12).

We anticipate this trial will be pragmatic, inclusive and representative of real-world Geriatric medicine inpatients. As such, we will include patients with pre-existing dementia and those residing in residential aged care facilities. This vulnerable population is at highest risk for delirium yet commonly under-represented in therapeutic trials.

An important aspect of this study will be patient tolerability of an inhaled nasal solution twice daily. Ward registered nurses administering intranasal insulin will receive training in both administration and subsequent documentation of the intervention. We will report on adherence and patients will be analysed on an intention-to-treat basis.

As duration of delirium is perhaps the most clinically relevant outcome for both clinicians and patients, we have chosen this as the primary outcome for the trial. The mean duration of delirium in Geriatric medicine inpatients has been demonstrated to be 8 +/- 9 days, however, symptoms of delirium can persist for up to 12 months (50). We anticipate some patients, particularly those returning to high level care residential aged care facilities, will be discharged with delirium and this group will be

**BMJ** Open

followed up daily for up to one week to assess for delirium resolution. Daily assessment after one week is beyond the allocated resources for this trial.

If found to be efficacious, this would lead to multicentre trials to confirm these findings. There would also be the opportunity to explore intranasal insulin in prevention of delirium and its role across settings, including in the intensive care and post-operative populations which also represent vulnerable patient groups.

Should the intervention reduce the duration of delirium the benefits to patients and their families could be significant, both in alleviating acute distress and longer-term negative sequelae of delirium. The treatment also has the potential to save significant financial resources related to both the acute treatment of delirium and the residual effects with regards to loss of independence and higher care needs after resolution of delirium. Finally, irrespective of the outcome, this trial will contribute to our understanding of the pathophysiological mechanisms of delirium particularly the role of impaired Y.C. cerebral perfusion and metabolism.

#### **Declarations**

Ethics approval and consent to participate: The trial methods, protocol and consent procedures were approved by the South Eastern Sydney Human Research and Ethics Committee (HREC 16\_320). As required by the New South Wales Guardianship act 1987 (part 5), New South Wales Civil and Administrative Tribunal, approval to conduct this clinical trial has also been obtained (case number 2017/00204946).

Consent for publication: Not applicable.

Availability of data and materials: Materials including data collection and consent forms can be accessed by contacting the corresponding author.

**Competing interest:** The authors declare that they have no competing interests.

# Reporting checklist for protocol of a clinical trial.

Based on the SPIRIT guidelines.

# **Instructions to authors**

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to include the missing information. If you are certain that an item does not apply, please write "n/a" and provide a short explanation.

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the SPIRITreporting guidelines, and cite them as:

Chan A-W, Tetzlaff JM, Gøtzsche PC, Altman DG, Mann H, Berlin J, Dickersin K, Hróbjartsson A, Schulz KF, Parulekar WR, Krleža-Jerić K, Laupacis A, Moher D. SPIRIT 2013 Explanation and Elaboration: Guidance for protocols of clinical trials. BMJ. 2013;346:e7586

1 2 3 4 5	Roles and responsibilities: sponsor contact	<u>#5b</u>	Name and contact information for the trial sponsor	16
6 7 8 9 10 11 12 13 14	information Roles and responsibilities: sponsor and funder	<u>#5c</u>	Role of study sponsor and funders, if any, in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities	16
15 16 17 18 19 20 21 22	Roles and responsibilities: committees	<u>#5d</u>	Composition, roles, and responsibilities of the coordinating centre, steering committee, endpoint adjudication committee, data management team, and other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	10, 11, 13
23 24	Introduction			
25 26 27 28	Background and rationale	<u>#6a</u>	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	3, 4, 8- 10
29 30 31 32 33	Background and rationale: choice of	<u>#6b</u>	Explanation for choice of comparators	8
34 35 36	comparators Objectives	#7	Specific objectives or hypotheses	5
37	Objectives	<u>#7</u>		5
38 39 40 41 42 43 44	Trial design	<u>#8</u>	Description of trial design including type of trial (eg, parallel group, crossover, factorial, single group), allocation ratio, and framework (eg, superiority, equivalence, non-inferiority, exploratory)	5
45 46	Methods:			
47	Participants,			
48 49	interventions, and			
50 51	outcomes			
51 52 53 54 55 56	Study setting	<u>#9</u>	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	5, 6
57 58 59 60	Eligibility criteria	<u>#10</u> For peer r	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will eview only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	6, 7

1			perform the interventions (eg, surgeons, psychotherapists)	
2 3 4 5 6 7 8 9 10	Interventions: description	<u>#11a</u>	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	8, 9
	Interventions: modifications	<u>#11b</u>	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving / worsening disease)	9 -11
11 12 13 14 15	Interventions: adherance	<u>#11c</u>	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return; laboratory tests)	11
16 17 18 19	Interventions: concomitant care	<u>#11d</u>	Relevant concomitant care and interventions that are permitted or prohibited during the trial	8
20 21 22 23 24 25 26 27 28 29	Outcomes	<u>#12</u>	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	11, 12
30 31 32 33 34	Participant timeline	<u>#13</u>	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	table 1
35 36 37 38 39 40	Sample size	<u>#14</u>	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	12
40 41 42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 59 60	Recruitment	<u>#15</u>	Strategies for achieving adequate participant enrolment to reach target sample size	6, 7
	Methods: Assignment of interventions (for controlled trials)			
	Allocation: sequence generation	<u>#16a</u> or peer re	Method of generating the allocation sequence (eg, computer- generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions eview only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	8

1 2 3 4 5 6	Allocation concealment mechanism	t <u>#16b</u>	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	8
7 8 9 10	Allocation: implementation	<u>#16c</u>	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	6-8
11 12 13 14 15 16	Blinding (masking)	<u>#17a</u>	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	8
17 18 19 20 21	Blinding (masking): emergency unblinding	<u>#17b</u>	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	10, 11
22 23	Methods: Data			
24	collection,			
25 26	management, and			
27 28	analysis			
28 29 30 31 32 33 34 35 36 37	Data collection plan	<u>#18a</u>	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	table 1, 13
38 39 40 41 42 43	Data collection plan: retention	<u>#18b</u>	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	7, 12
44 45 46 47 48 49 50	Data management	<u>#19</u>	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	13
51 52 53 54 55	Statistics: outcomes	<u>#20a</u>	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	12
56 57	Statistics: additional	<u>#20b</u>	Methods for any additional analyses (eg, subgroup and adjusted	12, 13
58	analyses		analyses)	
59 60		For peer re	eview only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

# 27 Abstract

Introduction: Delirium is one of the most common conditions diagnosed in hospitalised older people and is associated with numerous adverse outcomes, yet there are no proven pharmacological treatments. Recent research has identified cerebral glucose hypometabolism as a pathophysiological mechanism offering a therapeutic target in delirium. Insulin, delivered via the intranasal route, acts directly on the central nervous system and has been shown to enhance cerebral metabolism and improve cognition in patients with mild cognitive impairment and dementia. This trial will determine whether intranasal insulin can reduce the duration of delirium in older hospitalised patients.

Methods and analysis: This is a prospective randomised, placebo-controlled, double blind study with 6 months follow up. One hundred patients aged 65 years or older presenting to hospital with delirium admitted under Geriatric Medicine will be recruited. Participants will be randomised to intranasal insulin detemir or placebo administered twice daily until delirium resolves, defined as Confusion Assessment Method (CAM) negative for two days, or discharge from hospital. The primary outcome measure will be duration of delirium using the CAM. Secondary outcome measures will include length of hospital stay, severity of delirium, adherence to treatment, hospital complications, new admission to nursing home, mortality, use of antipsychotic medications during hospital stay and cognitive and physical function at 6-months post-discharge.

Ethics and dissemination: This trial has been approved by the South Eastern Sydney Human Research
and Ethics Committee. Dissemination plans include submission to a peer-reviewed journal for
publication and presentation at scientific conferences.

47 Trial registration: ACTRN12618000318280

50 The study design is pragmatic, inclusive and representative of real-world older hospitalised 51 patients who are often omitted from research due to multimorbidity. 52 The primary outcome, duration of delirium, is clinically relevant with longer duration of 53 delirium predicting worse outcomes in patients. 54 This is a single site trial based in Sydney, Australia therefore generalisability may be restricted. 55 Bedside assessment of delirium will occur daily rather than multiple times per day, meaning 56 57 diurnal fluctuations in behaviour will be captured by record review and informant history. Patients in this study will be reviewed in person by trained assessors daily for up to one-58 59 week post-discharge, however, assessment after one week is beyond the resources

allocated for this trial.

# 61 Background

Delirium is common, with figures reporting 10-35% of older people are delirious on admission to 62 63 hospital (prevalent delirium) and up to another 29% will become delirious during their admission 64 (incident delirium) (1). It is characterised by sudden and fluctuating disturbances in cognition, 65 attention and awareness (2). The sequelae of delirium are manifold and extend beyond the acute 66 hospitalisation; increased mortality, new cognitive impairment, accelerated dementia, loss of 67 independence and increased admission to nursing home(3, 4). In older patients, delirium is 68 independently associated with a two-fold increase in mortality at 12 months (5). Longer duration 69 and increased severity of delirium predict poorer outcomes in older patients (6).

Studies suggest that only 30% of incident delirium is potentially preventable with non-pharmacological
 multimodal intervention (7). Current management focuses on identifying and treating the underlying
 cause of delirium combined with non-pharmacological interventions to provide an optimal

**BMJ** Open

environment for brain recovery and reduce the risk of potentially avoidable complications such as fallsand pressure injuries.

Pharmacological management is focused on symptomatic control with antipsychotics. However,
evidence does not support the use of antipsychotics for delirium and a recent randomised controlled
trial demonstrated worsening symptoms and increased mortality (8, 9). At this point in time there are
no proven pharmacological interventions to prevent or manage delirium.

Delirium pathophysiology is poorly understood, although several hypotheses exist (10). These include neuroinflammation (11), neurotransmitter dysregulation (12), neuroendocrine dysregulation (13) and neural network dysconnectivity (14). As delirium is a complex and heterogeneous disorder, it is likely that several of these mechanisms may contribute to the development of delirium with varying effect depending on pre-existing patient vulnerabilities and the aetiology of the acute precipitant (15). However, regardless of the underlying cause, delirium presents in a recognisable and stereotyped manner (phenotypically hypoactive, hyperactive and mixed) and the hypothesis that a "final common pathway" may exist should not be disregarded.

Research has identified altered cerebral perfusion and metabolism as a feature of delirium. Delirious patients have higher cerebrospinal fluid (CSF) lactate and lower neuron-specific enolase suggesting suppressed aerobic metabolism during an episode of delirium (16, 17). Two studies have demonstrated cerebral glucose hypometabolism during delirium using fluorodeoxyglucose positron emission tomography (FDG-PET) (18, 19). Haggstrom et al have demonstrated a correlation between posterior cingulate cortex hypometabolism and attention as well as evidence of improved cortical glucose metabolism with resolution of delirium (18). Neuroimaging studies using a variety of modalities have demonstrated reduced cerebral perfusion, decreased cerebral oxygenation and abnormal cerebral autoregulation during an episode of delirium (20, 21). As cerebral blood flow and metabolism are closely coupled and considered to reflect synaptic activity(22), correction of perfusion and metabolism abnormalities may improve clinical outcomes in delirium.

98 It is now well established that the brain is an insulin sensitive organ; insulin receptors are widely
99 expressed in the brain, with greatest saturation in the corticolimbic structures (23). Insulin enhances
100 learning and memory by modulating neuronal growth, metabolism, plasticity and cholinergic function
101 (23, 24).

The role of glucose metabolism in the pathogenesis of neurodegenerative disease is a growing area of research (25). Mild Cognitive Impairment (MCI) and Alzheimer's Dementia (AD) have been characterised as states of brain-specific insulin resistance and deficiency sometimes called "type 3 diabetes" (26). Patients with early stage AD demonstrate pronounced insulin and insulin-like growth factor deficiency and resistance which progress with severity of neurodegeneration (23). Administration of intravenous (IV) insulin while maintaining fasting serum glucose levels improves memory in patients with Alzheimer's Disease (27). However, therapeutic administration of IV insulin is not feasible or safe due to the substantial risk of systemic hypoglycaemia.

The intranasal route of delivery provides a non-invasive and safe means of transporting insulin to the brain. A recent systematic review identified seven studies (total, N =293) examining the effect of intranasal insulin on MCI or AD, of which six demonstrated significant improvements in verbal memory (28). Positive outcomes in functional status were also observed (29-31). Improvements in attention, visuospatial memory and executive function have also been demonstrated in other populations (32-34).

One pilot trial has assessed the effect of intranasal insulin on delirium prevention in a cohort of 21 older cardiothoracic surgical patients (35). The incidence of postoperative delirium was lower in the intranasal group (18% vs 40%) although the result was not statistically significant, likely due to the small sample size. No serious adverse events were reported (36).

Given that intranasal insulin improves cognition as well as cerebral perfusion and metabolism, thistrial will investigate its potential role in treatment of delirium.

judged by the admitting geriatrician, c) have an allergy to insulin detemir formulation or d) a
structural abnormality precluding the use of the nasal drug delivery device, e) proven or suspected
COVID-19. People will also be excluded if consent is not obtained or they were previously enrolled in
the trial. Non-English-speaking patients who are unable to participate in cognitive assessments will
also be excluded. The trial will not include patients with incident delirium.

150 Screening and Evaluation of delirium

Within the emergency department or on transfer to the Geriatric Medicine Ward, all patients age
>64 years will be screened by nursing staff for delirium using the Confusion Assessment Method
(CAM) (38, 39). Patients with delirium diagnosed by a Geriatrician or Advanced Trainee in Geriatric
Medicine using the Diagnostic and Statistical Manual of Mental Disorders Fifth Edition criteria (DSM
5) will be considered for the trial (40).

156 Study team members will use the CAM to conduct daily delirium assessments between 12-2pm. All 157 members of the study team will undergo formal training using the CAM. Bedside assessment will be supplemented by review of the medical records and collateral history from the patient's carer or 158 159 ward staff where appropriate. The presence of delirium will be documented using the long form 160 CAM (38). Delirium severity will be assessed using the Delirium Index (DI) (41). Delirium clinical 161 subtype will be assessed using the abbreviated version of the Delirium Motor Subtyping Scale 162 (DMSS-4) (42). A Mini-Mental Status Examination (MMSE) will be used to complete the CAM and DI 163 during the initial assessment and a standardised structured assessment will be conducted on 164 subsequent days (see appendix A).

165 Interrater reliability using the CAM and DI will be assessed using Cohen's kappa coefficient based on
 166 twenty patient reviews (43).

1 2		
2 3 4 5	167	
6 7 8	168	Consent
9 10 11	169	Consent will involve conversations regarding the study risks, benefits and burdens between the
12 13	170	researchers, patient and the "person responsible" (substitute decision maker according to the New
14 15	171	South Wales Guardianship Act 1987). To avoid a delay in initiation of the intervention, where a
16 17	172	person responsible is unable to attend the hospital to sign the consent, an initial verbal consent may
18 19 20	173	be granted (by phone) and written consent obtained as soon as possible.
21 22	174	Consent to remain in the trial will be obtained from the patient if capacity returns. Should the
23 24 25	175	patient decline further involvement in the trial the researcher will ask the patient for consent to use
26 27	176	trial data up until the time of withdrawal in the final analysis.
28 29 30	177	Consent will also be obtained for the collection and study of patient blood specimens.
31 32 33 34	178	
35 36 37	179	Assessment over the study period
38 39	180	Table 1 highlights the measures to be undertaken at each pre-determined time point.
40 41	181	Measurements will be taken daily while receiving the intervention. Patient assessment will also
42 43 44	182	occur at discharge from hospital and 6 months post discharge.

201

193

1

Dementia status will be determined by a history of dementia diagnosis (informant history and
 medical record review) and/or an average IQCODE score >3.44 (44).

In addition to routine blood tests, 20millilitres of blood will be taken from each patient and stored
for later analysis, including the effect of Apolipoprotein E4 (APOE4) status on study outcomes.(56)
Specimens will be frozen and stored at -80 degrees Celsius in the University of New South Wales
Lowy Biorepository.

194 Randomisation and blinding

Permutated block randomisation will be conducted with a block size of 4 and 25 blocks using a
computer-generated algorithm. An independent clinical trials pharmacist will create the
randomisation schedule which will be provided to the clinical trials pharmacy staff responsible for
production and dispensing of the medication. Each vial of insulin or placebo will be labelled with a
sequentially allocated randomisation number, which will become that patient's study number.

200 Participants, research and ward staff will be blinded to treatment allocation.

202 Intervention

Patients will receive 20 international units (IU) of long-acting insulin (detemir) or a placebo of normal
saline intranasally twice daily at 8am and 8pm via a commercially available drug delivery device
(ViaNase delivery device, Kurve Technology, Bothell, Washington). This device has been used
successfully in previous trials of intranasal insulin in cognitive impairment (30, 31). The device will
release 20IU insulin detemir or placebo intranasally via a small nose piece over a 40 second period.
Patients will receive 20 seconds per nostril twice daily and during administration be instructed to
breath normally through the nose.

1 2		
2 3 4	210	Following intranasal administration, insulin enters the brain either through direct entry via the
5 6	211	cribriform plate and the olfactory nerves or via specific receptors in the blood-brain barrier or a
7 8 9	212	combination of the two (57). In 15-30 minutes, insulin peptides are detected within the cerebral
9 10 11	213	cortex and hippocampus (58). Compared to the subcutaneous route, intranasal administration of
12 13	214	insulin demonstrates an approximately 2000-fold increase in the AUC <sub>brain:plasma</sub> ratio, meaning at
14 15	215	similar doses the intranasal route reaches comparable or increased brain insulin concentration but
16 17	216	substantially lower plasma concentration (59).
18 19 20	217	The total daily dose of 401U of insulin detemir is based on research by Claxton et. al demonstrating
21 22	218	safety and efficacy in older patients with Alzheimer's dementia. In this trial, 60 patients with mild
23 24	219	cognitive impairment or mild-to-moderate AD received either placebo, 20IU of insulin detemir, or
25 26 27	220	40IU of insulin detemir intranasally for 21 days. Participants receiving 40IU of insulin detemir
28 29	221	demonstrated significant improvements in verbal and visuospatial working memory. No statistically
30 31	222	significant effect was found in the 20IU detemir group. No treatment-related severe adverse events
32 33 34	223	were reported (56).
35 36 37	224	Pre-prepared, spare vials and in-use devices will be stored between 2-8 degrees Celsius in the ward
38 39	225	medication fridge.
40 41	226	The medication will be administered by ward registered nurses specifically trained for the trial.
42 43 44 45 46 47 48 49 50 51 52 53 54 55 56	227	Nurses will record challenges regarding administration of the intervention, including partially
	228	received or omitted doses, in the electronic patient record which will be reviewed by trial staff daily.
	229	The intervention will cease following two consecutive CAM negative days; this criteria has been
	230	successfully adopted in other studies assessing delirium duration.(60) The intervention will be
	231	discontinued for patients with subsyndromal delirium (defined by the presence of one or more CAM
	232	symptoms without meeting the criteria for delirium) (61).
57 58	233	Cessation of treatment with the study intervention will also occur if:
59 60	234	The patient is discharged from the hospital

3 4	235	Patient or treating clinician requests discontinuation				
5 6	236	Unacceptable side effects from study medications (defined by National Cancer Institute				
7 8	237	Common Criteria for Adverse Events; Common Terminology Criteria for Adverse Events				
9 10 11	238	version 4.0)				
12 13	239	• Participants who in the opinion of the investigator are not well enough to continue in the				
14 15	240	study				
16 17 18	241	Adverse events related to the study medicine are unacceptable to the participant/carer or				
19 20	242	clinician in charge e.g. symptomatic or severe hypoglycaemia (blood sugar level <3.0mmol/L)				
21 22	243	• Treatment is deemed ineffective, defined as no improvement in delirium index over 7 days.				
23 24 25	244	Patients withdrawn from the study will be included in statistical analysis on an intention-to-treat				
26 27	245	basis.				
28 29	246	If delirium recurs after resolution of the initial episode (i.e. hospital acquired delirium) the				
30 31 32	247	intervention will not be recommenced.				
33 34						
35 36	248					
37 38 39	249	Safety				
40 41	250	Studies have demonstrated that less than 3% of intranasally-delivered insulin is detectable in the				
42 43						
44 45	251	serum and as a result intranasal insulin has a negligible risk of hypoglycaemia (28, 62). A systematic				
46 47	252	review on the safety of intranasal insulin included 38 studies (N=1092) and found no cases of				
48 49	253	hypoglycaemia or severe adverse events (63). The most commonly reported side effects were				
50 51	254	transient and local to the nasal area including nasal tingling and burning, less commonly rhinitis and				
52 53	255	nasal bleeding occurred.				
54 55 56	256	Although the risk of hypoglycaemia is largely theoretical, blood glucose levels will be measured at				
56 57 58	257	baseline and four times daily during the study intervention (07:00, 13:00, 19:00, 22:00). As adequate				
58 59	237					

1 2		
2 3 4	258	and uninterrupted sleep is a core principle in delirium management and disturbed sleep can
5 6 7	259	precipitate or exacerbate delirium, blood glucose levels will not be taken overnight.
8 9	260	Adverse events will be assessed daily through participant interview supplemented by review of the
10 11 12 13 14	261	electronic medical record. Serious adverse events as defined by the International Conference on
	262	Harmonisation Guidelines for Good Clinical Practice will be reported in accordance with local ethics
15 16	263	requirements. An independent data and safety monitoring board (DSMB) will oversee the study and
17 18	264	meet after each twenty patients. Serious adverse events will be discussed with the lead investigator
19 20	265	immediately and reported to the Human Research Ethics Committee (HREC) and trial DSMB within
21 22 23 24 25 26 27 28 29 30	266	24 hours.
	267	Delirium is associated with a high in-hospital mortality rate, previously demonstrated to reach 35% in
	268	an older population (64). As such, a key role of DSMB will be to review all deaths and serious adverse
	269	events in detail to determine if the adverse event was in keeping with the natural history of the illness
31 32	270	or could be attributed to the study intervention (65). Should concerns arise regarding patient safety
33 34 35	271	the DSMB may request to unblind for decision making purposes.
36 37 38 39 40 41 42	272	There are two main scenarios which could prompt DSMB to request termination of the study. Firstly,
	273	if there are a significant number of serious adverse events possibly attributed to the intervention
	274	leading to patient safety concerns and secondly, significant benefit from the intervention. Should
43 44	275	termination of the trial be requested, researchers would be unblinded and data analysis would
45 46	276	occur. The HREC and participants would be informed the trial was stopped and reasons for
47 48 49	277	termination given.
50 51 52	278	
53 54 55	279	Outcomes
56 57 58	280	The primary and secondary outcomes are outlined in table 1. The primary outcome will be duration
59 60	281	of delirium in days. Delirium assessment will be conducted daily from enrolment until delirium

resolution, defined as two consecutive days (48hours) CAM negative. Patients discharged with delirium will be followed up in person daily for up to one week to assess for delirium resolution. Secondary outcomes will determine if intranasal insulin compared to placebo decreases acute length of hospital stay, reduces severity of delirium, reduces hospital complications, reduces new admission to nursing home, decreases mortality and decreases use of antipsychotic medications during an inpatient stay. Patients will be followed up at 6 months post-discharge to assess if intranasal insulin reduces mortality and preserves cognition and function. Adherence to the intervention will be measured by percentage of doses successfully administered.

#### 291 Sample size

Power analysis (with 5% significance and 80% power) was performed using published data which
shows the mean duration of delirium clustered at approximately 8 days in Geriatric medicine ward
populations(66, 67). Power calculation shows reducing delirium duration by two days (from 8 days to
6 days) requires 36 in each arm for a total of 72 patients. Allowing for a 30% dropout rate, a total of
100 participants will be sought.

298 Statistical Analysis

Statistical analysis will be conducted using IBM SPSS Statistics software. An intention-to-treat
approach will be adopted for all analyses and statistical significance assumed at the level of 5%
(P<0.05). Baseline characteristics will be reported for the overall population and separately for each</li>
group.

303 The primary outcome, duration of delirium measured in days, will be analysed first with a Mann 304 Whitney U test which has high statistical power (68) and then using survival analysis Cox

#### BMJ Open

305	proportional hazard method including dementia, nursing home status, severity of acute illness
306	(APACHE III) and comorbidity as covariates. Sensitivity analysis will be conducted using normality-
307	improving data transformations or Gamma regression with a log link according to the distribution of
308	the primary outcome. Analysis will include in hospital death as a competing risk. For the major
309	secondary outcome, trajectory of delirium severity measured by the delirium index over time, a
310	generalised linear mixed model will be used. Binary outcomes like mortality (in-hospital and at six
311	months) and institutionalisation will be evaluated using a modified Poisson regression (69). A linear
312	regression will assess possible preservation of function, measured by Barthel index (45) and
313	modified Instrumental Activities of Daily Living (46), and for all other linear secondary outcomes.
314	Bootstrapping will be applied if the models fail to satisfy the normality assumptions. For length of
315	hospital stay, a log-linear or gamma regression with a log link will be implemented. The number of
316	hospital complications and the use of antipsychotics during hospitalization will be reported.
317	Subgroup analysis stratifying by age, sex, dementia and APOE status will be conducted.
318	
510	Data Management
319	Data Management
320	Data will be collected by trained researchers and stored on a password protected database. One
321	researcher will be responsible for data entry while another member of the study team will monitor
322	the accuracy of data by cross-checking a random 10% sample of subjects.
222	
323	Paper files of individual records will be stored in a locked cabinet in a secure location accessible to
324	authorised members of the study team only. Electronic data will be entered in a de-identified format
325	and stored on a password-protected secure server. The complete data set will be stored on the
326	University of New South Wales Data Archive and will be made available at the completion of the trial
327	on reasonable request.

#### 

## 329 Patient and public involvement

A public representative approved trial concept, design and consent procedures as part of the
 application to New South Wales Civil and Administrative Tribunal.

## 333 Ethics and dissemination:

The trial methods, protocol and consent procedures were approved by the South Eastern Sydney Human Research and Ethics Committee (HREC 16\_320). Results of the trial will be published in biomedical journals and presented at international scientific conferences. Social media platforms will be used to inform the general public about the results. Authorship on publications related to this study will follow standard eligibility guidelines ensuring significant contribution.

#### 

## 340 Discussion

Delirium is a debilitating condition commonly affecting older people in hospital and for which there are no registered treatments. It has been consistently demonstrated that longer duration of delirium predicts worse outcomes, including higher mortality and new admission to residential aged care facility (6, 70). Although the pathophysiological mechanisms are incompletely understood, it is probable that an episode of delirium causes irreversible neuronal damage leading to sustained cognitive and functional impairment (71), with prolonged delirium exposure leading to greater cerebral damage.

To date, there are no trials assessing intranasal insulin as a treatment for delirium, however, it could improve cognitive and clinical outcomes for delirious patients via a variety of mechanisms. Intranasal insulin increases cerebral perfusion (33, 72-74) and increases or maintains cerebral glucose metabolism on FDG-PET (75, 76). In young healthy adults and patients with type II diabetes mellitus,

#### **BMJ** Open

intranasal insulin enhances functional connectivity within the default mode network, an important centre for higher cognitive processes in which delirious patients demonstrate dysconnectivity (14, 77, 78). The hypothalamic-pituitary-adrenal (HPA) axis is also insulin responsive and following administration of intranasal insulin healthy populations demonstrate diminished saliva and plasma cortisol (32, 79). As aberrant HPA axis activity is hypothesised to contribute to delirium pathophysiology, modification of this pathway may also lead to improved outcomes (13).

358 We anticipate this trial will be pragmatic, inclusive and representative of real-world Geriatric medicine 359 inpatients. As such, we will include patients with pre-existing dementia and those residing in 360 residential aged care facilities. This vulnerable population is at highest risk for delirium yet commonly 361 under-represented in therapeutic trials.

An important aspect of this study will be patient tolerability of an inhaled nasal solution twice daily. Ward registered nurses administering intranasal insulin will receive training in both administration and subsequent documentation of the intervention. We will report on adherence and patients will be analysed on an intention-to-treat basis.

As duration of delirium is perhaps the most clinically relevant outcome for both clinicians and patients, we have chosen this as the primary outcome for the trial. The mean duration of delirium in Geriatric medicine inpatients has been demonstrated to be 8 +/- 9 days, however, symptoms of delirium can persist for up to 12 months (66). We anticipate some patients, particularly those returning to high level care residential aged care facilities, will be discharged with delirium and this group will be followed up daily for up to one week to assess for delirium resolution. Daily assessment after one week is beyond the allocated resources for this trial.

If found to be efficacious, this would lead to multicentre trials to confirm these findings. There would
 also be the opportunity to explore intranasal insulin in prevention of delirium and its role across
 settings, including in the intensive care and post-operative populations which also represent
 vulnerable patient groups.

Should the intervention reduce the duration of delirium the benefits to patients and their families could be significant, both in alleviating acute distress and longer-term negative sequelae of delirium. The treatment also has the potential to save significant financial resources related to both the acute treatment of delirium and the residual effects with regards to loss of independence and higher care needs after resolution of delirium. Finally, irrespective of the outcome, this trial will contribute to our understanding of the pathophysiological mechanisms of delirium particularly the role of impaired cerebral perfusion and metabolism.

# **Declarations**

Ethics approval and consent to participate: The trial methods, protocol and consent procedures
were approved by the South Eastern Sydney Human Research and Ethics Committee (HREC 16\_320).
As required by the New South Wales Guardianship act 1987 (part 5), New South Wales Civil and
Administrative Tribunal, approval to conduct this clinical trial has also been obtained (case number
2017/00204946).

**Consent for publication:** Not applicable.

392 Availability of data and materials: Materials including data collection and consent forms can be

393 accessed by contacting the corresponding author.

**Competing interest:** The authors declare that they have no competing interests.

5 395 **Funding:** This trial is financially supported by the JJ Mason and HS Williams Memorial Foundation,

The Julia Lowy Foundation and the Harry Triguboff Foundation. Award/Grant number not applicable.

<sup>0</sup> 397 The funding bodies have no role in trial design, trial conduct, data management, analysis,

398 interpretation of the data, writing of the manuscript or decision to publish.

**Disclosures:** MA receives delirium clinical trial funding from Cancer Australia.

7 400 **Author contributions:** GC initiated the study and is the trial sponsor. AN, AM and GC designed the

59 401 original protocol. JC and MA provided substantial input in study processes and logistics. BTu 60

Flect	onic Medical Record Review
21000	Administration of intervention:
	- Review if administered successfully, review nursing notes regarding administration,
	tolerability and side effects.
	Review glycaemic control.
	Review nursing and medical notes <sup>*</sup> :
	- Evidence of fluctuating levels of consciousness and behaviour, disturbed sleep cycle
	perceptual changes including hallucinations.
	- Evidence of hospital acquired complications.
	- New prescription of antipsychotics or benzodiazepines.
Infor	nant history from patient's family and health care workers where available.
Patie	nt review
	General observations*:
	<ul> <li>Alertness, level of consciousness, motor activity, hallucinations.</li> </ul>
	Trial related questions:
	- Does the patient recall receiving the intervention? Side effects? Nasal irritation? Tri
	related issues?
	Orientation and thought content:
	- Assess orientation <sup>*</sup> to: date of birth, current year, place, age, day of week, month.
	- Is the patient aware of the reason for hospitalisation? Duration of hospital admissio
	<ul> <li>If required consider specific questions to assess disorganised thinking<sup>#</sup> (Does a ston- float on water? Are there fish in the sea? Do you hit a nail with a hammer?)</li> </ul>
	Registration <sup>*</sup> :
	<ul> <li>Three-word registration (rotating words daily to avoid learning bias)</li> </ul>
	Attention:
	<ul> <li>Ability to participate in conversation and shift attention.</li> </ul>
	- Five letter word backwards <sup>*</sup> (rotating single syllable words daily to avoid learning bi
	<ul> <li>Months of the year backwards (&lt;7 months)</li> </ul>
	<ul> <li>Supplementary tests as required<sup>#</sup><sup>^</sup>: SAVEAHAART (≥2 errors), days of the week</li> </ul>
	backwards (≥1 errors), five-digit span forwards(≥1 errors), three-digit span
	backwards(≥1 errors).
	Recall <sup>*</sup>
	Assessment of perceptual abnormalities:
	<ul> <li>Have you seen and experienced anything unusual or unexpected*?</li> </ul>
	<ul> <li>Other questions: Do you feel safe? Do you think anyone is out to harm you? Are you being well looked after in the hospital?</li> </ul>
Comr	•
comp	<ul> <li>blete short and long from confusion assessment method and delirium index.</li> <li>If the patient is negative on the short form confusion assessment for two consecutive days cease the trial.</li> </ul>
	red for delirium index/long-form confusion assessment method

<sup>^</sup>Consider if lower education, learning bias suspected

Based on the SPIRIT guidelines.

# Instructions to authors

provide a short explanation.

Complete this checklist by entering the page numbers from your manuscript where readers will find each of the items listed below.

Your article may not currently address all the items on the checklist. Please modify your text to

include the missing information. If you are certain that an item does not apply, please write "n/a" and

Upload your completed checklist as an extra file when you submit to a journal.

In your methods section, say that you used the SPIRITreporting guidelines, and cite them as:

Chan A-W, Tetzlaff JM, Gøtzsche PC, Altman DG, Mann H, Berlin J, Dickersin K, Hróbjartsson A,

Schulz KF, Parulekar WR, Krleža-Jerić K, Laupacis A, Moher D. SPIRIT 2013 Explanation and

Elaboration: Guidance for protocols of clinical trials. BMJ. 2013;346:e7586

information			
Title	<u>#1</u>	Descriptive title identifying the study design, population, interventions, and, if applicable, trial acronym	1

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

1 2	Trial registration	<u>#2a</u>	Trial identifier and registry name. If not yet registered,	2
3 4 5 7 8 9 10 11 12 13			name of intended registry	
	Trial registration:	<u>#2b</u>	All items from the World Health Organization Trial	6,7
	data set		Registration Data Set	
	Protocol version	<u>#3</u>	Date and version identifier	N/A
14 15 16 17 18	Funding	<u>#4</u>	Sources and types of financial, material, and other support	17
19 20 21 22	Roles and	<u>#5a</u>	Names, affiliations, and roles of protocol contributors	1, 17
23 24	responsibilities:			
25 26 27	contributorship			
27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51	Roles and	<u>#5b</u>	Name and contact information for the trial sponsor	17
	responsibilities:			
	sponsor contact			
	information			
	Roles and	<u>#5c</u>	Role of study sponsor and funders, if any, in study	17
	responsibilities:		design; collection, management, analysis, and	
	sponsor and funder		interpretation of data; writing of the report; and the	
			decision to submit the report for publication, including	
			whether they will have ultimate authority over any of	
			these activities	
52 53	Roles and	<u>#5d</u>	Composition, roles, and responsibilities of the	11, 12,
54 55	responsibilities:		coordinating centre, steering committee, endpoint	14
56 57 58	committees		adjudication committee, data management team, and	
59 60	Fc	or peer rev	view only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2 3			other individuals or groups overseeing the trial, if applicable (see Item 21a for data monitoring committee)	
4 5 6 7	Introduction			
8 9 10	Background and	<u>#6a</u>	Description of research question and justification for	3-5, 9-10
10 11 12	rationale		undertaking the trial, including summary of relevant	
13 14 15 16			studies (published and unpublished) examining benefits	
			and harms for each intervention	
17 18	De al construction and	#0h	Eventeen for chains of commonstant	0
19 20	Background and	<u>#6b</u>	Explanation for choice of comparators	9
21 22 23	rationale: choice of			
24 25	comparators			
25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42	Objectives	<u>#7</u>	Specific objectives or hypotheses	5
	<b></b>			0
	Trial design	<u>#8</u>	Description of trial design including type of trial (eg,	6
			parallel group, crossover, factorial, single group),	
			allocation ratio, and framework (eg, superiority,	
			equivalence, non-inferiority, exploratory)	
	Methods:			
	Participants,			
43 44	interventions, and			
45 46				
47 48	outcomes			
49 50	Study setting	<u>#9</u>	Description of study settings (eg, community clinic,	6,7
51 52			academic hospital) and list of countries where data will	
53 54			be collected. Reference to where list of study sites can	
55 56 57			be obtained	
57 58 59				
60		For peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2	Eligibility criteria	<u>#10</u>	Inclusion and exclusion criteria for participants. If	6, 7
3 4			applicable, eligibility criteria for study centres and	
5 6 7			individuals who will perform the interventions (eg,	
7 8 9 10			surgeons, psychotherapists)	
11 12	Interventions:	<u>#11a</u>	Interventions for each group with sufficient detail to allow	9,10
13 14	description		replication, including how and when they will be	
15 16 17 18			administered	
19 20	Interventions:	<u>#11b</u>	Criteria for discontinuing or modifying allocated	10-12
21 22	modifications		interventions for a given trial participant (eg, drug dose	
23 24			change in response to harms, participant request, or	
25 26			improving / worsening disease)	
27 28	Interventions:	#11c	Stratagios to improve adherance to intervention	11-12
29 30 31		<u>#110</u>	Strategies to improve adherence to intervention	11-12
32 33	adherance		protocols, and any procedures for monitoring adherence	
34 35			(eg, drug tablet return; laboratory tests)	
36 37	Interventions:	<u>#11d</u>	Relevant concomitant care and interventions that are	9
38 39 40	concomitant care		permitted or prohibited during the trial	
41 42 42	Outcomes	<u>#12</u>	Primary, secondary, and other outcomes, including the	12
43 44 45			specific measurement variable (eg, systolic blood	
46 47			pressure), analysis metric (eg, change from baseline,	
48 49			final value, time to event), method of aggregation (eg,	
50 51			median, proportion), and time point for each outcome.	
52 53 54			Explanation of the clinical relevance of chosen efficacy	
55 56			and harm outcomes is strongly recommended	
57 58				
59 60	F	or peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2	Participant timeline	<u>#13</u>	Time schedule of enrolment, interventions (including any	table 1
3 4 5 6 7 8 9 10 11 12			run-ins and washouts), assessments, and visits for	
			participants. A schematic diagram is highly	
			recommended (see Figure)	
	Sample size	<u>#14</u>	Estimated number of participants needed to achieve	12
13 14			study objectives and how it was determined, including	
15 16 17			clinical and statistical assumptions supporting any	
17 18 19 20			sample size calculations	
20 21 22	Recruitment	<u>#15</u>	Strategies for achieving adequate participant enrolment	7
23 24			to reach target sample size	
25 26 27	Methods:			
28 29 30	Assignment of			
30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 48 49 50 51 52 53 54	interventions (for			
	controlled trials)			
	Allocation: sequence	<u>#16a</u>	Method of generating the allocation sequence (eg,	8
	generation		computer-generated random numbers), and list of any	
			factors for stratification. To reduce predictability of a	
			random sequence, details of any planned restriction (eg,	
			blocking) should be provided in a separate document that	
			is unavailable to those who enrol participants or assign	
			interventions	
	Allocation	<u>#16b</u>	Mechanism of implementing the allocation sequence (eg,	8,9
55 56	concealment		central telephone; sequentially numbered, opaque,	
57 58	mechanism			
59 60	Fo	r peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1			sealed envelopes), describing any steps to conceal the	
2 3 4			sequence until interventions are assigned	
5 6 7	Allocation:	<u>#16c</u>	Who will generate the allocation sequence, who will enrol	6-9
8 9	implementation		participants, and who will assign participants to	
10 11			interventions	
12 13 14	Blinding (masking)	<u>#17a</u>	Who will be blinded after assignment to interventions (eg,	9
15 16			trial participants, care providers, outcome assessors,	
17 18			data analysts), and how	
19 20				
21 22	Blinding (masking):	<u>#17b</u>	If blinded, circumstances under which unblinding is	11,12
23 24	emergency		permissible, and procedure for revealing a participant's	
25 26 27 28	unblinding		allocated intervention during the trial	
29 30	Methods: Data			
31 32	collection,			
33 34	management, and			
35 36	analysis			
37 38			0.	
39 40	Data collection plan	<u>#18a</u>	Plans for assessment and collection of outcome,	table 1,
41 42			baseline, and other trial data, including any related	14
43 44			processes to promote data quality (eg, duplicate	
45 46			measurements, training of assessors) and a description	
47 48			of study instruments (eg, questionnaires, laboratory tests)	
49 50 51			along with their reliability and validity, if known.	
51 52 53			Reference to where data collection forms can be found, if	
54 55			not in the protocol	
56 57				
58 59				
60	Fc	or peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2	Data collection plan:	<u>#18b</u>	Plans to promote participant retention and complete	8, 13
3 4 5 6 7 8 9 10 11 2 13 14 15 16 17 8 9 20 21 22 34 25 26 27 28 9 30 122 23 4 5 26 27 28 9 30 132 33 4 5 6 37 8 9 40 41 42 34 45 6 7 8 9 0 11 22 34 5 6 7 8 9 0 11 22 23 45 26 27 8 9 30 132 33 45 36 37 8 9 40 41 42 34 45 6 5 7 8 9 0 11 22 34 5 6 7 8 9 0 11 22 34 5 6 7 8 9 30 12 23 45 26 27 8 9 30 132 33 45 36 37 8 9 40 41 42 43 44 5 6 5 7 8 9 0 12 23 45 6 7 8 9 0 12 23 45 26 27 8 9 30 122 23 45 26 27 8 9 30 122 33 45 56 57 8 9 00 122 33 45 56 57 8 9 00 122 33 45 56 57 8 9 00 122 33 45 56 57 8 9 00 122 33 45 56 57 8 9 00 122 3 3 45 56 57 8 9 00 122 3 3 45 56 57 8 9 00 122 3 54 55 6 57 8 9 00 122 3 54 55 6 57 8 9 00 122 3 54 55 6 57 8 9 00 122 3 54 55 6 57 8 9 00 122 3 54 55 6 57 8 9 00 122 3 54 55 6 57 8 9 00 12 53 56 57 8 9 00 12 53 56 57 56 57 8 9 60 12 53 56 57 56 57 8 9 60 1 25 57 56 57 57 57 56 57 57 57 57 57 57 57 57 57 57 57 57 57	retention		follow-up, including list of any outcome data to be	
			collected for participants who discontinue or deviate from	
			intervention protocols	
	Data management	<u>#19</u>	Plans for data entry, coding, security, and storage,	13
			including any related processes to promote data quality	
			(eg, double data entry; range checks for data values).	
			Reference to where details of data management	
			procedures can be found, if not in the protocol	
	Statistics: outcomes	<u>#20a</u>	Statistical methods for analysing primary and secondary	13
			outcomes. Reference to where other details of the	
			statistical analysis plan can be found, if not in the	
			protocol	
	Statistics: additional	<u>#20b</u>	Methods for any additional analyses (eg, subgroup and	13
	analyses		adjusted analyses)	
	Statistics: analysis	<u>#20c</u>	Definition of analysis population relating to protocol non-	13
	population and		adherence (eg, as randomised analysis), and any	
	missing data		statistical methods to handle missing data (eg, multiple	
			imputation)	
	Methods: Monitoring			
	Data monitoring:	<u>#21a</u>	Composition of data monitoring committee (DMC);	11, 13
	formal committee		summary of its role and reporting structure; statement of	
			whether it is independent from the sponsor and	
	For	peer revi	ew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2 3 4 5 6 7 8 9 10 11	Data monitoring:	#21b	competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation of why a DMC is not needed Description of any interim analyses and stopping	10- 12
12				
13 14	interim analysis		guidelines, including who will have access to these	
15 16			interim results and make the final decision to terminate	
17 18			the trial	
19 20		C		
21	Harms	<u>#22</u>	Plans for collecting, assessing, reporting, and managing	10-12
22 23			solicited and spontaneously reported adverse events and	
24 25			other unintended effects of trial interventions or trial	
26 27			conduct	
28 29				
30 31	Auditing	<u>#23</u>	Frequency and procedures for auditing trial conduct, if	11
32 33			any, and whether the process will be independent from	
34 35			investigators and the sponsor	
36 37				
38 39	Ethics and			
39 40 41 42	dissemination			
43 44	Research ethics	<u>#24</u>	Plans for seeking research ethics committee / institutional	14
45 46	approval		review board (REC / IRB) approval	
47 48				
49 50	Protocol	<u>#25</u>	Plans for communicating important protocol modifications	6
50 51 52	amendments		(eg, changes to eligibility criteria, outcomes, analyses) to	
53 54			relevant parties (eg, investigators, REC / IRBs, trial	
55 56 57			participants, trial registries, journals, regulators)	
58 59 60		For peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2	Consent or assent	<u>#26a</u>	Who will obtain informed consent or assent from potential	7-8
3 4			trial participants or authorised surrogates, and how (see	
5 6 7			Item 32)	
8 9 10	Consent or assent:	<u>#26b</u>	Additional consent provisions for collection and use of	7-8
11 12	ancillary studies		participant data and biological specimens in ancillary	
13 14 15 16 17 18			studies, if applicable	
	Confidentiality	<u>#27</u>	How personal information about potential and enrolled	14
18 19 20			participants will be collected, shared, and maintained in	
21 22			order to protect confidentiality before, during, and after	
23 24 25			the trial	
26 27	Declaration of	<u>#28</u>	Financial and other competing interests for principal	16-17
28 29 30	interests		investigators for the overall trial and each study site	
31 32 33	Data access	<u>#29</u>	Statement of who will have access to the final trial	14
34 35			dataset, and disclosure of contractual agreements that	
36 37 38			limit such access for investigators	
39 40	Ancillary and post	<u>#30</u>	Provisions, if any, for ancillary and post-trial care, and for	table 1
41 42	trial care		compensation to those who suffer harm from trial	
43 44 45			participation	
46 47 48	Dissemination policy:	<u>#31a</u>	Plans for investigators and sponsor to communicate trial	14
49 50	trial results		results to participants, healthcare professionals, the	
51 52			public, and other relevant groups (eg, via publication,	
53 54 55			reporting in results databases, or other data sharing	
56 57 58			arrangements), including any publication restrictions	
59 60	Fo	r peer rev	iew only - http://bmjopen.bmj.com/site/about/guidelines.xhtml	

1 2	Dissemination policy:	<u>#31b</u>	Authorship eligibility guidelines and any intended use of	14	
3 4 5	authorship		professional writers		
6 7	Dissemination policy:	<u>#31c</u>	Plans, if any, for granting public access to the full	14	
8 9 10	reproducible		protocol, participant-level dataset, and statistical code		
11 12 13	research				
14 15 16	Appendices				
17 18	Informed consent	<u>#32</u>	Model consent form and other related documentation	attached	
19 20 21	materials		given to participants and authorised surrogates		
22 23 24	Biological specimens	<u>#33</u>	Plans for collection, laboratory evaluation, and storage of	8	
24 25 26			biological specimens for genetic or molecular analysis in		
27 28			the current trial and for future use in ancillary studies, if		
29 30			applicable
