

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Objectives: Health registries are a unique source of information about current practice and can describe disease burden in a population. We aimed to understand similarities and differences in the German Resuscitation Registry (GRR) and the Norwegian Cardiac Arrest Registry (NorCAR) and compare incidence and survival for patients resuscitated after out-of-hospital cardiac arrest.

Design: A cross-sectional comparative analysis reporting incidence and outcome on a population level.

Setting: We included data from the cardiac arrest registries in Germany and Norway.

Participants: Patients resuscitated between 1st January 2015 and 31st December 2019 were included, resulting in 29,222 cases from GRR and 16,406 cases from NorCAR. From GRR, only emergency medical services (EMS) reporting survival information for patients admitted to hospital were included.

Primary and secondary outcome measures: This study focused on the EMS systems, the registries, and the patients included in both registries. The results compare the total incidence, incidence of patients resuscitated by EMS and the incidence of survival.

Results: We found an incidence of 68 per 100,000 inhabitants in GRR and 63 in NorCAR. The incidence of patients treated by EMS was 67 in GRR and 53 in NorCAR. The incidence of patients arriving at a hospital was higher in GRR (24.3) than in NorCAR (15.1), but survival was similar (8 in GRR and 7.8 in NorCAR).

Conclusion: GRR is a voluntary registry, and in-hospital information is not reported for all cases. NorCAR has mandatory reporting from all EMS and hospitals. EMS in Germany starts treatment on more patients and bring a higher number to hospital, but we found no difference

1
2
3 in the incidence of survival. This study has improved our knowledge of both registries and
4
5 highlighted the importance of reporting survival as incidence when comparing registries.

18 **ARTICLE SUMMARY**

19 **Strengths and limitations of this study:**

- 20
21
22
23 • Prospective cardiac arrest registries provide knowledge about treatment and results in
24
25 real life in contrast to highly selected populations in clinical studies.
26
27
- 28 • When analysing data from different systems and countries, results must be related to
29
30 the population covered to increase comparability.
31
32
- 33 • In our study, overall survival on a population level is similar in Germany and Norway,
34
35 in contrast to prior publications that have compared survival rates as percentages of
36
37 the EMS treated patients.
38
39
- 40 • In Germany, the General Data Protection Regulation interpretation is associated with
41
42 more missing information on survival status than results from the Norwegian registry.

INTRODUCTION

Health registries are a unique source of information about current practice and the first of many steps in improving treatment and care¹. Registries can be used for epidemiological and outcome reports for many health conditions, describe the burden of disease and the effectiveness of treatment. Registries can also be beneficial in quality improvement projects,² and for political accountability. Registries on out-of-hospital cardiac arrest (OHCA) are of particular interest as a successful outcome depends on a complex chain involving the population, medical dispatch, emergency medical services and hospital treatment³.

For a society to improve survival after OHCA, detailed and reliable data must guide our efforts. Several studies and reviews have compared outcomes across countries and jurisdictions⁴⁻⁸. Despite the international consensus of which data to collect and how to collect it,⁹ results vary greatly, even within groups presumed to have similar characteristics^{10 11}. Survival is often reported as rates and not as incidence per 100,000 inhabitants, making comparisons almost impossible due to the varying denominator.

This study aimed to understand the German Resuscitation Registry (GRR) and the Norwegian Cardiac Arrest Registry (NorCAR) and compare the incidence of included patients and survival. As a background for our analysis, we describe the care provided to OHCA patients and data collection into the registries. We present incidence and outcome in the catchment areas and the Utstein comparator group (witnessed by a bystander and having a shockable rhythm)⁹.

METHODS

Healthcare in Germany

Germany is a federal parliamentary republic consisting of 16 states and covers 357,386 square kilometres (km²). In 2019 Germany had 85 million inhabitants. The population density was about 238 inhabitants per km² ¹².

The emergency medical services (EMS) in Germany is a two-tiered system consisting of emergency medical technicians (EMT) or paramedics and emergency-physician. Teaching paramedics often have education on a bachelor level, but this is not common for paramedics working in the field. Ambulances personnel provide primary care and patient transportation, and a medical vehicle or helicopter carries an emergency physician to the patient location for all cardiac arrest situations¹³.

A standard emergency number, 1-1-2, terminates at an Emergency Medical Communications Centres (EMCC). EMTs or paramedics are call-takers. Each state organises their specialist health care, resulting in differences in the EMCCs. There are 1,900 hospitals with a 24/7 emergency department, resulting in 23 hospitals per 1 million inhabitants. Due to German data protection laws, using a single patient identification number in health care is not possible. Health insurance or the state covers health care in Germany¹².

Hospitals with an internal medicine department and an emergency department treat patients that survive to hospital admission. Recently a unique certification for cardiac-arrest centres

1
2
3 was established. To get certified, hospitals must fulfil criteria, including 24/7 Percutaneous
4
5 Coronary Intervention (PCI) service and have protocols for post-cardiac arrest care.
6
7
8
9

10 **Healthcare in Norway**

11
12 Norway is a representative democratic constitutional monarchy covering a total land area of
13
14 304,282 km² and had 5.3 million inhabitants in 2019. The population density is about 18
15
16 inhabitants per km² ¹².
17
18
19
20

21 The EMS in Norway consists of ambulances, boats and helicopters, search and rescue
22
23 helicopters, small aeroplanes and physician-manned cars. The helicopters, planes and
24
25 physician-manned cars have rescue-EMS personnel and an anesthesiologist/emergency
26
27 physician. Ambulance personnel have an education level of minimum upper secondary school
28
29 and a two-year apprenticeship. In recent years, several universities have established bachelor
30
31 programs for paramedics.
32
33
34
35
36

37 The Norwegian single-payer public insurance covers all aspects of health care, including the
38
39 ambulance service. For medical emergencies, there is a dedicated telephone number, 1-1-3,
40
41 that terminates at 16 local EMCC. Nurses and ambulance personnel receive the calls.
42
43

44 Specialist health care is organised in four regional and 19 local health trusts, with 50 hospitals
45
46 with an emergency department, resulting in 9.4 hospitals per 1 million inhabitants¹². Based on
47
48 national recommendations, all hospitals have protocols for care for patients surviving to
49
50 hospital admission. Within each region in Norway, referral hospitals offer 24/7 PCI, and
51
52 bypass protocols are in place. A personal identification number identifies the patient in all
53
54 contact with specialist health care.
55
56
57

58
59 7
60

The German resuscitation registry (GRR)

GRR is a voluntary based registry established in 2007 by the German Society of Anaesthesiology and Intensive Care Medicine. In 2019, GRR received information from EMS covering 26.6 million inhabitants (31% of the inhabitants of Germany and with EMS from all parts of the country). The registry includes fully anonymised data from patients suffering cardiac arrest both outside and in the hospital. In addition to data collection and benchmarking, GRR provides risk adjustment analysis for its participants^{14 15}.

The inclusion criteria in GRR is; all EMS attended cardiac arrests. Participants in the registry enter information from the EMS services and may add in-hospital treatment, survival to hospital discharge, and 30-day survival if this information is available. Due to different interpretations of the General Data Protection Regulation (GDPR), in-hospital treatment of OHCA patients is not always available for the reporting EMS system. An area with good data quality has; an incidence above 30/100,000 inhabitants per year, ROSC in less than 80% of cases, information about ROSC-after-cardiac-arrest in more than 60% of the cases, and, if relevant, documented hospital care available for more than 30% of the cases¹⁶.

The Norwegian Cardiac Arrest Registry (NorCAR)

National Advisory Unit on Prehospital Emergency Medicine established NorCAR in 2002, and the registry received status as a mandatory national health registry in September 2013.

The registry includes cardiac arrests both outside and in the hospital. By May 2016, all health trusts reported OHCA to the registry. Oslo University Hospital hosts the registry, and the Norwegian Institute of Public Health has the legal responsibility¹⁷.

8

1
2
3
4
5 Inclusion criteria in the registry is; patients suffering cardiac arrest, where bystanders, first
6 responders or healthcare professionals start any kind of treatment. Treatment is basic or
7 advanced cardiopulmonary resuscitation (CPR) or defibrillation. Patients suffering cardiac
8 arrest that do not receive any CPR are not included in the registry¹⁷.
9
10
11
12
13
14
15
16

17 **Participants**

18
19 This study included all patients from NorCAR and all patients where resuscitation was
20 attempted from areas in GRR with good data quality. The patients had a cardiac arrest
21 between 1st January 2015 and 31st December 2019.
22
23
24
25
26
27

28 **Variables**

29
30 All data variables in the registries are available in the local languages. Variables were
31 translated into English to make comparison possible and to ensure an equal understanding of
32 the definitions. Although both registries use the Utstein definitions, the German registry
33 reports any return of spontaneous circulation (ROSC) while the Norwegian registry reports
34 sustained ROSC (ROSC for more than 20 minutes or to hospital admission). Therefore, the
35 shared data points “Transport to hospital” and “Arrival to hospital with ROSC” was used. For
36 the overall survival, we used survival to hospital discharge in GRR and 30-day survival in
37 NorCAR.

51 **Patient and Public Involvement**

52
53 NorCARs steering committee has a user representative who has been actively involved in
54 planning this and earlier projects in NorCAR. He represents the patient organisation National
55
56
57

1
2
3 Association of Heart and Lung Disease (LHL) with 54,000 members. Through his network of
4 fellow user representatives, he provides a channel for communication to the patient population
5 and the boards of the health trusts. At several meetings, the user representative has expressed
6 concern regarding the difficulties of comparing data from different regions in Norway and
7 differences between countries. We believe this study addresses these challenges, and we also
8 suggest a method for reducing the reported differences by presenting results as incidence, not
9 at percentages.

21 **Checklist**

22
23 The STROBE cross-sectional reporting guideline was used when formatting the manuscript¹⁸.
24
25
26
27
28
29

30 **STATISTICAL METHODS**

31
32 We provide descriptive measures as mean with standard deviation (SD) or median, as
33 appropriate according to the data distribution. We calculated incidence for regions reporting
34 part of a year by dividing the number of patients by the corresponding fraction of the person-
35 years for that region. For bystander efforts (CPR and use of public defibrillators) and
36 calculation of EMS response intervals, we excluded EMS witnessed cardiac arrests. We
37 analysed the Utstein comparator group based on the 2014 definition,⁹ including patients with
38 a bystander-witnessed collapse and an initial shockable rhythm. For the cause of arrest, we
39 used the Utstein definition from 2004¹⁹. During several personal meetings, we reviewed the
40 results and rechecked the analyses. Figures 1 and 2 describe the inclusion and exclusion of
41 patients in GRR and NorCAR. Analyses were carried out using IBM SPSS Statistics 27. P-

values are calculated based on the incidence, and a p-value <0.05 was considered statistically significant.

RESULTS

Demographics

Between 2015 and 2019, 29,222 cases were registered in GRR (68 per 100,000 inhabitants) and 16,406 cases in NorCAR (63 per 100,000 inhabitants). The patients in GRR were older than the patients in NorCAR, more often had presumed cardiac cause, had a shockable rhythm and were more likely to be unwitnessed (Table 1). Gender and the location of arrest were similar.

Table 1: Cardiac arrest characteristics for all resuscitated patients in GRR and NorCAR, 2015-2019.

All patients included in the analysis	GRR N = 29222	NorCAR N = 16406	P-value
Incidence per 100,000 inhabitants	68.2	63.2	p<0.001
Age in years - Median (IQR)	73 (60-82)	68 (54-79)	p<0.001
Age in years – missing	195	17	
Male (%)	19109 (65)	10906 (66)	p=0.021
Gender – missing	5	-	
At home (%)	18242 (62)	10122 (62)	p=0.124

Location - missing	151	98	
Presumed cardiac cause (%)	21793 (75)	10990 (67)	p<0.001
Initial rhythm shockable (%)	6753 (23)	3253 (20)	p<0.001
Initial rhythm – missing (%)	100 (<1)	2301 (14)	
Witnessed status (%)			p<0.001
Bystander witnessed (%)	12622 (43)	8403 (51)	p<0.001*

EMS witnessed (%)	3688 (13)	1861 (11)	P=0.001*
CA not witnessed (%)	12455 (43)	6124 (35)	p<0.001*
CA witnessed – missing (%)	58 (<1)	7 (<1)	p<0.001*

GRR – German Resuscitation Registry – areas with good data quality, NorCAR – Norwegian Cardiac Arrest Registry, CPR – cardiopulmonary resuscitation, CA – cardiac arrest, EMS – emergency medical service. * P-values from post hoc testing (chi-square test) and corrected by the Bonferroni method.

All patients except EMS witnessed cardiac arrests

The incidence of patients receiving bystander CPR, having a public defibrillator connected, and receiving a shock before EMS arrival was higher in NorCAR than in GRR, giving a higher number of patients successfully resuscitated before EMS arrival (Table 2).

Table 2: Patients resuscitated by bystander or EMS, except EMS and first responder witnessed cardiac arrests.

All patients except EMS and first responder witnessed	GRR N=25135	NorCAR N=14545	P-value
Incidence per 100,000 inhabitants	58.7	55.2	p<0.001
Median response interval in minutes (IQR)	8 (6-10)	9 (6-14)	p<0.001
Response interval - missing (%)	608 (2)	252 (2)	
Bystander CPR (%)	1056 (44)	11803 (82)	p<0.001
Public defibrillator connected (%)	482 (2)	853 (6)	p<0.001
Shock by public defibrillator if attached (%) *	126 (26)	260 (30)	p<0.001
Shocked by public defibrillator before EMS arrival, and ROSC on EMS arrival (%)	107 (0.4)	116 (0.8)	p<0.001

GRR – German Resuscitation Registry – areas with good quality data, NorCAR – Norwegian

Cardiac Arrest Registry, EMS – emergency medical service, CPR – cardiopulmonary

*resuscitation. * Percentage of connected defibrillators*

The median response interval was 8 minutes in GRR (IQR 6-10) and 9 minutes in NorCAR (IQR 6-14). In NorCAR, the EMS personnel chooses not to start resuscitation, despite bystanders having started CPR, in 16% of the patients, most of whom had a pulse on EMS arrival. The proportion of patients not treated by EMS in GRR was 1%.

CPR by EMS

The reported incidence of patients resuscitated by EMS per 100,000 inhabitants was 67 in GRR and 53 in NorCAR. More patients were declared dead on scene in NorCAR, while the incidence of patients “Transported to hospital” and “Arrival to hospital with ROSC” was

higher in GRR. (Table 3) The incidence of 24-hour survival was higher in GRR, but there was no statistical difference in overall survival. (Figure 3)

Table 3: Outcome for all EMS-treated patients per 100,000 inhabitants

CPR by EMS	GRR N=28786	NorCAR N=13704	P-value
Incidence of EMS treated patients	67.2	52.8	p<0.001
Incidence of transport to hospital (%)*	31.7 (47)	19.5 (37)	p<0.001
Status on arrival to hospital			
Incidence of arrival with ROSC (%)	24.3 (36)	15.1 (29)	p<0.001
Incidence of arrival with ongoing CPR (%)	7.4 (11)	4.1 (8)	p<0.001
Incidence of 24-hour survival (%) **	15.5 (23)	13.7 (24)	p<0.001
Incidence of survival (%) ***	8.0 (12)	7.8 (15)	p=0.42

GRR – German Resuscitation Registry – areas with good quality data, NorCAR – Norwegian Cardiac Arrest Registry, ROSC – return of spontaneous circulation, CPR - cardiopulmonary resuscitation, EMS – emergency medical service, PCI - Percutaneous Coronary Intervention.

* Declared dead/transport to hospital – missing 265 (1%) in GRR and 104 (1%) in NorCAR,

** 24-hour survival – missing 2273 (8%) in GRR and 195 (1%) in NorCAR

*** Survival – missing 1931 (7%) in GRR and 165 (1%) in NorCAR

The use of a mechanical chest compressions device was higher in NorCAR than in GRR (4020 of 13704 (29%) vs 3223 of 28786 (11%) respectively, p<0.001). For patients transported to hospital and arriving with ROSC or ongoing CPR, 1987 of 13571 (15%) of the

patients in GRR and 1079 of 4962 (22%) of the patients in NorCAR were transported directly to the PCI lab on arrival.

Utstein comparator group

The incidence of patients in the Utstein group was higher in GRR, but they constituted a smaller proportion of the EMS-treated population (14 vs 17 %). Bystander CPR was higher in NorCAR (1961 of 2274 (86%)) than in GRR (2726 of 4155 (66%)). For patients transported to hospital and arriving with ROSC or ongoing CPR, 879 of 3362 (26%) of the patients in GRR and 548 of 1502 (37%) of the patients in NorCAR were transported directly to the PCI lab on arrival. The incidence of prehospital ROSC and survival to 24-hours was higher in GRR (Table 4 and Figure 4), but the incidence of overall survival was higher in NorCAR.

Table 4: Outcome for the Utstein comparator group per 100,000 inhabitants

Utstein comparator group	GRR N=4155	NorCAR N= 2274	P-value
Incidence in the Utstein comparator group	9.7	8.8	p<0.001
Incidence of transport to hospital (%) *	7.8 (81)	6.2 (71)	p<0.001
Status on arrival to hospital			
Incidence of arrival to hospital with ROSC (%)	6.4 (66)	5.0 (57)	p<0.001
Incidence of arrival to hospital with ongoing CPR (%)	1.4 (15)	0.8 (9)	p<0.001
Incidence of 24-hour survival (%) **	5.0 (13)	5.2 (54)	p=0.21
Incidence of survival (%) ***	3.5 (36)	3.8 (43)	p=0.04

18 **DISCUSSION**

19
20
21 The incidence of cardiac arrest per 100,000 inhabitants is higher in GRR compared to
22
23 NorCAR. GRR reports a higher incidence of EMS treated patients, a higher incidence of
24
25 patients transported to the hospital and a higher incidence of patients arriving in the hospital
26
27 with ROSC. The overall incidence of survival is similar in both countries. For the Utstein
28
29 comparator group, the incidence of survival is marginally higher in NorCAR. Patient
30
31 characteristics in both countries, such as age and gender, confirms previous reports⁶.
32
33
34
35
36

37 Using registry data from two different countries, we encountered some challenges. A certain
38
39 amount of recoding of variables had to be done, notably using survival to hospital discharge
40
41 in GRR and 30-day survival in NorCAR. Both survival to discharge, and 30-day survival,
42
43 have been used interchangeably in other international studies, including the latest
44
45 recommendations for reporting⁹. Also, in a registry, it is not easy to verify the completeness
46
47 of cases²⁰. Most EMS services in Europe have a paper-based reporting system, and there are
48
49 no electronically available patient charts to use as controls. Both GRR and NorCAR are
50
51 dependent on the attending EMS personnel remembering to submit a form after the event.
52
53
54 This form is then manually entered into the registry database by data managers.

3
4
5 Comparing a voluntary registry with a mandatory registry, we were worried about missing
6 information. In the latest published update on uniform reporting of cardiac arrest, the Utstein
7 reporting format, the authors stress the importance of reducing missing information⁹. We
8 found that the rate of missing information is overall higher in GRR, and the variable with the
9 highest missing rate is survival (7 %). Survival information is mostly missing from entire
10 hospitals, indicating that missing cases include both survivors and non-survivors. Due to GRR
11 being a voluntary registry, information on cardiac arrest cases is not available from the entire
12 country. Results are, however, comparable to overall results in yearly reports from GRR and
13 the data in this study are considered to be representable for all regions reporting to the
14 registry¹⁶.

30

31 Reporting the incidence of cardiac arrest is primarily done using the number of patients per
32 100,000 inhabitants in the population served by the EMS⁶⁻⁸. Survival, however, is often
33 presented as a proportion of the EMS treated patients. Percentages are presumed to be easier
34 to understand and make comparability with already published data more straightforward.
35 During the Covid-19 pandemic, healthcare professionals and the general public have become
36 more used to population incidence as a measurement, and we believe it is time for survival
37 after cardiac arrest to be published in this way. In 1993, Becker et al.²¹ published an analysis
38 on the relationship between reported incidence and survival rates and advised incidence and
39 not percentages. When there is more than a 3-fold difference in the incidence of EMS treated
40 patients, as reported in the latest EuReCa study,⁶ higher survival rates do not necessarily
41 represent better quality of care. The difference could be that a registry with a low survival
42 percentage is better at identifying all patients resuscitated by the EMS. Our study shows that
43 the incidence of survival is similar in GRR and NorCAR, but the incidence of included

59
60

1
2
3 patients is not. If we calculate the survival rate based on the number of patients resuscitated
4
5 by the EMS, Norway seems to have better survival (15%) than Germany (12%).
6
7
8
9

10 Differences in the incidence of cardiac arrest overall, and the EMS treated patients in
11
12 particular, could be due to differences in public health in general and cardiovascular health in
13
14 particular. According to the European Unions' statistics, cardiovascular disease deaths account
15
16 for 37% of deaths in Germany, but only 26% in Norway²². Population density, geography and
17
18 placement of ambulances might also have an impact. Both countries adhere to European
19
20 guidelines for resuscitation,²³ but in Norway, withholding care in the prehospital setting is
21
22 more common.
23
24
25
26
27

28 Response interval is the time interval from a call is received at an EMCC to the first
29
30 ambulance arrives at the defined address. Response interval should ideally include the delay
31
32 until EMS personnel are at the patient side, but the latter time point remains elusive due to
33
34 manual registration. The extended response interval in Norway provides dispatchers more
35
36 time to help bystanders start CPR, connect and use a defibrillator, and is associated with a
37
38 significantly higher number of patients having been successfully resuscitated before EMS
39
40 arrival. On the downside, it probably also has a negative effect on survival^{24 25}. The narrow
41
42 distribution of response intervals in GRR (25- and 75-percentiles of 6 and 10 minutes)
43
44 compared with the broader distribution found in NorCAR (25- and 75-percentiles of 6 and 14
45
46 minutes) indicates differences caused by geography and population density. Extended
47
48 response intervals might also explain the lower incidence of EMS treated patients in Norway
49
50 as bystanders or EMS personnel perceive resuscitation as futile when the response interval is
51
52 prolonged.
53
54
55
56
57
58
59
60

1
2
3 The Utstein comparator group is a sub-group that enables comparison between countries⁹.
4
5 This sub-group has a more uniform treatment recommendation than the total population of
6
7 patients with OHCA and does not include cases with unknown delay from collapse. Our
8
9 results confirm that the differences between our countries also extends to this specific group.
10
11 Differences between countries in the Utstein comparator group have been shown in several
12
13 studies previously^{6 10 26}.
14
15
16
17
18

19 In Norway, all hospitals are state-owned, and the Norwegian Directory of Health issues
20
21 guidelines for treatment. Results from quality registries are published yearly, naming and
22
23 shaming hospitals and their adherence to guidelines²⁷. There is a bypass protocol for the
24
25 nearest University Hospital capable of performing PCI for cardiac arrest patients. If transport
26
27 duration is prolonged, there are guidelines for prehospital treatment, including thrombolysis.
28
29 In Norway, the in-hospital treatment after OHCA is standardised, but this is not the case in
30
31 most German hospitals. In 2019, the German Resuscitation Council started an initiative to
32
33 certify cardiac arrest centres, and GRR extended the benchmarking facilities for cardiac arrest
34
35 centres²⁸.
36
37
38
39
40
41

42 Several factors are associated with increased survival after OHCA; younger age, presumed
43
44 cardiac cause, shockable first rhythm, witnessed collapse, location of arrest in a public place,
45
46 bystander CPR, early shock by a defibrillator, a short time from collapse to arrival of EMS
47
48 and good post-resuscitation care including temperature control and PCI^{14 29}. Compared to
49
50 GRR, the patients in NorCAR are younger, witnessed collapse is more common and more
51
52 than four out of five receive bystander CPR. Compared to NorCAR, the patients in GRR more
53
54 often have presumed cardiac cause, initial rhythm is shockable, and the EMS's response
55
56 interval is shorter. There is a mix of factors associated with survival in both countries.
57
58
59
60

1
2
3
4
5 This study has helped us identify differences and similarities in the cardiac arrest registries in
6 Germany and Norway and identify potential confounders for future studies. In this
7
8 comparison, we cannot tease out the relative importance of factors associated with increased
9
10 survival, and in future studies, we should analyse individual cases using more sophisticated
11
12 statistical methods.
13
14
15
16
17
18
19

20 CONCLUSION

21
22
23 This cross-sectional study shows the importance of comparing the incidence of survival based
24 on the population served and not on the percentage of EMS treated patients. When comparing
25
26 data from OHCA registries, especially when comparing survival, we recommend using
27
28 incidence per 100,000 inhabitants, and we believe it is time to stop reporting survival as
29
30 percentages.
31
32
33
34
35
36

37 We found that the EMS in Germany started CPR on a higher number of cardiac arrest
38 patients, and the incidence of patients transported to the hospital and arriving with ROSC is
39
40 higher than in NorCAR. We speculate that the difference in overall incidence and incidence of
41
42 EMS treated patients is due to an interaction between response intervals, bystander CPR, age
43
44 and EMS organisation. A multivariate analysis should be performed to better understand our
45
46 findings.

Reporting checklist for cross sectional study.

	Reporting Item	Page Number
Title and abstract		
Title	#1a Indicate the study's design with a commonly used term in the title or the abstract	1
Abstract	#1b Provide in the abstract an informative and balanced summary of what was done and what was found	3
Introduction		
Background / rationale	#2 Explain the scientific background and rationale for the investigation being reported	5
Objectives	#3 State specific objectives, including any prespecified hypotheses	5
Methods		
Study design	#4 Present key elements of study design early in the paper	5
Setting	#5 Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6-10
Eligibility criteria	#6a Give the eligibility criteria, and the sources and methods of selection of participants.	9
	#7 Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	9
Data sources / measurement	#8 For each variable of interest give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group. Give information separately for for exposed and unexposed groups if applicable.	8-9
Bias	#9 Describe any efforts to address potential sources of bias	16
Study size	#10 Explain how the study size was arrived at	n/a, all patients were included

1	Quantitative	#11	Explain how quantitative variables were handled in the	10-11
2	variables		analyses. If applicable, describe which groupings were chosen,	
3			and why	
4				
5

ABSTRACT

Objectives: Health registries are a unique source of information about current practice and can describe disease burden in a population. We aimed to understand similarities and differences in the German Resuscitation Registry (GRR) and the Norwegian Cardiac Arrest Registry (NorCAR) and compare incidence and survival for patients resuscitated after out-of-hospital cardiac arrest.

Design: A cross-sectional comparative analysis reporting incidence and outcome on a population level.

Setting: We included data from the cardiac arrest registries in Germany and Norway.

Participants: Patients resuscitated between 1st January 2015 and 31st December 2019 were included, resulting in 29,222 cases from GRR and 16,406 cases from NorCAR. From GRR, only emergency medical services (EMS) reporting survival information for patients admitted to hospital were included.

Primary and secondary outcome measures: This study focused on the EMS systems, the registries, and the patients included in both registries. The results compare the total incidence, incidence of patients resuscitated by EMS and the incidence of survival.

Results: We found an incidence of 68 per 100,000 inhabitants in GRR and 63 in NorCAR. The incidence of patients treated by EMS was 67 in GRR and 53 in NorCAR. The incidence of patients arriving at a hospital was higher in GRR (24.3) than in NorCAR (15.1), but survival was similar (8 in GRR and 7.8 in NorCAR).

Conclusion: GRR is a voluntary registry, and in-hospital information is not reported for all cases. NorCAR has mandatory reporting from all EMS and hospitals. EMS in Germany starts treatment on more patients and bring a higher number to hospital, but we found no difference

1
2
3 in the incidence of survival. This study has improved our knowledge of both registries and
4
5 highlighted the importance of reporting survival as incidence when comparing registries.

18 **ARTICLE SUMMARY**

19 **Strengths and limitations of this study:**

- 20
21
22
23 • Prospective cardiac arrest registries provide knowledge about treatment and results in
24
25 real life in contrast to highly selected populations in clinical studies.
- 26
27
28 • We used data from a mandatory registry covering an entire country and from a
29
30 voluntary registry covering parts of a country.
- 31
32
33 • We use incidence per 100,000 inhabitants when presenting the rate of cases and the
34
35 rate of survival in the out-of-hospital cardiac arrest population.
- 36
37
38 • In Germany, the General Data Protection Regulation interpretation is associated with
39
40 more missing information on survival status than results from the Norwegian registry.

INTRODUCTION

Health registries are a unique source of information about current practice and the first of many steps in improving treatment and care¹. Registries can be used for epidemiological and outcome reports for many health conditions, describe the burden of disease and the effectiveness of treatment. Registries can also be beneficial in quality improvement projects,² and for political accountability. Registries on out-of-hospital cardiac arrest (OHCA) are of particular interest as a successful outcome depends on a complex chain involving the population, medical dispatch, emergency medical services and hospital treatment³.

For a society to improve survival after OHCA, detailed and reliable data must guide our efforts. Several studies and reviews have compared outcomes across countries and jurisdictions⁴⁻⁸. Despite the international consensus of which data to collect and how to collect it,⁹ results vary greatly, even within groups presumed to have similar characteristics^{10 11}.

Survival is often reported as rates and not as incidence per 100,000 inhabitants, making comparisons almost impossible due to the varying denominator. Two big studies reporting on cardiac arrest in Europe both reported return of spontaneous circulation (ROSC) and survival as percentages and not as incidence.^{6 8} The same use of percentages can be seen in the yearly reports from the Cardiac Arrest Registry to Enhance Survival (CARES) in USA¹² and the first report from the International Liaison Committee on Resuscitation.⁷

This study aimed to understand the German Resuscitation Registry (GRR) and the Norwegian Cardiac Arrest Registry (NorCAR), to compare the EMS systems in Germany and Norway,

1
2
3 and to report on the treatment given to patients suffering out-of-hospital cardiac arrest. We
4
5 also aimed to compare a mandatory and a voluntary registry, the incidence of included
6
7 patients, and incidence of survival. As a background for our analysis, we describe the care
8
9 provided to OHCA patients and data collection into the registries. We present incidence and
10
11 outcome in the catchment areas and the Utstein comparator group (witnessed by a bystander
12
13 and having a shockable rhythm)⁹.
14
15
16
17
18
19

20 21 **METHODS**

22 23 **Healthcare in Germany**

24
25 Germany is a federal parliamentary republic consisting of 16 states and covers 357,386 square
26
27 kilometres (km²). In 2019 Germany had 85 million inhabitants. The population density was
28
29 about 238 inhabitants per km² ¹³.
30
31
32
33
34

35 The emergency medical services (EMS) in Germany is a two-tiered system consisting of
36
37 emergency medical technicians (EMT) or paramedics and emergency-physician. Teaching
38
39 paramedics often have education on a bachelor level, but this is not common for paramedics
40
41 working in the field. Ambulances personnel provide primary care and patient transportation,
42
43 and a medical vehicle or helicopter carries an emergency physician to the patient location for
44
45 all cardiac arrest situations¹⁴.
46
47
48
49
50

51 A standard emergency number, 1-1-2, terminates at an Emergency Medical Communications
52
53 Centres (EMCC). EMTs or paramedics are call-takers. Each state organises their specialist
54
55 health care, resulting in differences in the EMCCs. There are 1,900 hospitals with a 24/7
56
57
58
59
60

6

1
2
3 emergency department, resulting in 23 hospitals per 1 million inhabitants. Due to German
4 data protection laws, using a single patient identification number in health care is not possible.
5
6
7 Health insurance or the state covers health care in Germany¹³.
8
9

10
11
12 Hospitals with an internal medicine department and an emergency department treat patients
13 that survive to hospital admission. Recently a unique certification for cardiac-arrest centres
14 was established. To get certified, hospitals must fulfil criteria, including 24/7 Percutaneous
15 Coronary Intervention (PCI) service and have protocols for post-cardiac arrest care.
16
17
18
19
20
21
22

23 **Healthcare in Norway**

24
25
26 Norway is a representative democratic constitutional monarchy covering a total land area of
27 304,282 km² and had 5.3 million inhabitants in 2019. The population density is about 18
28 inhabitants per km² ¹³.
29
30
31
32
33
34

35 The EMS in Norway consists of ambulances, boats and helicopters, search and rescue
36 helicopters, small aeroplanes and physician-manned cars. The helicopters, planes and
37 physician-manned cars have rescue-EMS personnel and an anesthesiologist/emergency
38 physician. Ambulance personnel have an education level of minimum upper secondary school
39 and a two-year apprenticeship. In recent years, several universities have established bachelor
40 programs for paramedics.
41
42
43
44
45
46
47
48
49
50

51 The Norwegian single-payer public insurance covers all aspects of health care, including the
52 ambulance service. For medical emergencies, there is a dedicated telephone number, 1-1-3,
53 that terminates at 16 local EMCC. Nurses and ambulance personnel receive the calls.
54
55
56
57
58
59
60

1
2
3 Specialist health care is organised in four regional and 19 local health trusts, with 50 hospitals
4 with an emergency department, resulting in 9.4 hospitals per 1 million inhabitants¹³. Based on
5 national recommendations, all hospitals have protocols for care for patients surviving to
6 hospital admission. Within each region in Norway, referral hospitals offer 24/7 PCI, and
7 bypass protocols are in place. A personal identification number identifies the patient in all
8 contact with specialist health care.
9
10

12
13
14
15
16
17
18

19 **The German resuscitation registry (GRR)**

20
21 GRR is a voluntary based registry established in 2007 by the German Society of
22 Anaesthesiology and Intensive Care Medicine. In 2019, GRR received information from EMS
23 covering 26.6 million inhabitants (31% of the inhabitants of Germany and with EMS from all
24 parts of the country). The registry includes fully anonymised data from patients suffering
25 cardiac arrest both outside and in the hospital. In addition to data collection and
26 benchmarking, GRR provides risk adjustment analysis for its participants^{15 16}.
27
28
29
30
31
32
33
34
35
36
37

38 The inclusion criteria in GRR is; all EMS attended cardiac arrests. Participants in the registry
39 enter information from the EMS services and may add in-hospital treatment, survival to
40 hospital discharge, and 30-day survival if this information is available. Due to different
41 interpretations of the General Data Protection Regulation (GDPR), in-hospital treatment of
42 OHCA patients is not always available for the reporting EMS system. An area with good data
43 quality has; an incidence above 30/100,000 inhabitants per year, ROSC in less than 80% of
44 cases, information about ROSC-after-cardiac-arrest in more than 60% of the cases, and, if
45 relevant, documented hospital care available for more than 30% of the cases¹⁷.

The Norwegian Cardiac Arrest Registry (NorCAR)

National Advisory Unit on Prehospital Emergency Medicine established NorCAR in 2002, and the registry received status as a mandatory national health registry in September 2013.

The registry includes cardiac arrests both outside and in the hospital. By May 2016, all health trusts reported OHCA to the registry. Oslo University Hospital hosts the registry, and the Norwegian Institute of Public Health has the legal responsibility¹⁸.

Inclusion criteria in the registry is; patients suffering cardiac arrest, where bystanders, first responders or healthcare professionals start any kind of treatment. Treatment is basic or advanced cardiopulmonary resuscitation (CPR) or defibrillation. Patients suffering cardiac arrest that do not receive any CPR are not included in the registry¹⁸.

Participants

This study included all patients from NorCAR and all patients where resuscitation was attempted from areas in GRR with good data quality. The patients had a cardiac arrest between 1st January 2015 and 31st December 2019.

Variables

All data variables in the registries are available in the local languages. Variables were translated into English to make comparison possible and to ensure an equal understanding of the definitions. Although both registries use the Utstein definitions, the German registry reports any ROSC while the Norwegian registry reports sustained ROSC (ROSC for more than 20 minutes or to hospital admission). Therefore, the shared data points “Transport to

1
2
3 hospital” and “Arrival to hospital with ROSC” was used. For the overall survival, we used
4
5 survival to hospital discharge in GRR and 30-day survival in NorCAR.
6
7
8
9

10 **Patient and Public Involvement**

11
12 NorCARs steering committee has a user representative who has been actively involved in
13
14 planning this and earlier projects in NorCAR. He represents the patient organisation National
15
16 Association of Heart and Lung Disease (LHL) with 54,000 members. Through his network of
17
18 fellow user representatives, he provides a channel for communication to the patient population
19
20 and the boards of the health trusts. At several meetings, the user representative has expressed
21
22 concern regarding the difficulties of comparing data from different regions in Norway and
23
24 differences between countries. We believe this study addresses these challenges, and we also
25
26 suggest a method for reducing the reported differences by presenting results as incidence, not
27
28 at percentages.

41
42

43 **STATISTICAL METHODS**

44
45
46 We provide descriptive measures as mean with standard deviation (SD) or median, as
47
48 appropriate according to the data distribution. We calculated incidence for regions reporting
49
50 part of a year by dividing the number of patients by the corresponding fraction of the person-
51
52 years for that region. For bystander efforts (CPR and use of public defibrillators) and
53
54 calculation of EMS response intervals, we excluded EMS witnessed cardiac arrests. We
55
56
57

58
59 10
60

1
2
3 analysed the Utstein comparator group based on the 2014 definition,⁹ including patients with
4 a bystander-witnessed collapse and an initial shockable rhythm. For the cause of arrest, we
5 used the Utstein definition from 2004²⁰. During several personal meetings, we reviewed the
6 results and rechecked the analyses. Figures 1 and 2 describe the inclusion and exclusion of
7 patients in GRR and NorCAR. Analyses were carried out using IBM SPSS Statistics 27. P-
8 values are calculated based on the incidence, and a p-value <0.05 was considered statistically
9 significant.

23 RESULTS

24 Demographics

25
26 Between 2015 and 2019, 29,222 cases were registered in GRR (68 per 100,000 inhabitants)
27 and 16,406 cases in NorCAR (63 per 100,000 inhabitants). The patients in GRR were older
28 than the patients in NorCAR, more often had presumed cardiac cause, had a shockable rhythm
29 and were more likely to be unwitnessed (Table 1). Gender and the location of arrest were
30 similar.

GRR – German Resuscitation Registry – areas with good data quality, NorCAR – Norwegian Cardiac Arrest Registry, CPR – cardiopulmonary resuscitation, CA – cardiac arrest, EMS – emergency medical service. * P-values from post hoc testing (chi-square test) and corrected by the Bonferroni method.

All patients except EMS witnessed cardiac arrests

The incidence of patients receiving bystander CPR, having a public defibrillator connected, and receiving a shock before EMS arrival was higher in NorCAR than in GRR, giving a higher number of patients successfully resuscitated before EMS arrival (Table 2).

Table 2: Patients resuscitated by bystander or EMS, except EMS and first responder witnessed cardiac arrests.

	GRR	NorCAR	P-value
All patients except EMS and first responder witnessed	N=25135	N=14545	
Incidence per 100,000 inhabitants	58.7	55.2	p<0.001
Median response interval in minutes (IQR)	8 (6-10)	9 (6-14)	p<0.001
Response interval - missing (%)	608 (2)	252 (2)	
Bystander CPR (%)	11056 (44)	11803 (82)	p<0.001

Shock by public defibrillator if connected (%) *	126 (26)	260 (30)	p<0.001
Shocked by public defibrillator before EMS arrival, and ROSC on EMS arrival (%)	107 (0.4)	116 (0.8)	p<0.001

GRR – German Resuscitation Registry – areas with good quality data, NorCAR – Norwegian Cardiac Arrest Registry, EMS – emergency medical service, CPR – cardiopulmonary resuscitation. * Percentage calculated based on the number of connected public defibrillators

The median response interval was 8 minutes in GRR (IQR 6-10) and 9 minutes in NorCAR (IQR 6-14). In NorCAR, the EMS personnel chooses not to start resuscitation, despite bystanders having started CPR, in 16% of the patients, most of whom had a pulse on EMS arrival. The proportion of patients not treated by EMS in GRR was 1%.

CPR by EMS

The reported incidence of patients resuscitated by EMS per 100,000 inhabitants was 67 in GRR and 53 in NorCAR. More patients were declared dead on scene in NorCAR, while the

13

incidence of patients “Transported to hospital” and “Arrival to hospital with ROSC” was higher in GRR. (Table 3) The incidence of 24-hour survival was higher in GRR, but there was no statistical difference in overall survival. (Figure 3)

Table 3: Outcome for all EMS-treated patients per 100,000 inhabitants

CPR by EMS	GRR N=28786	NorCAR N=13704	P-value
Incidence of EMS treated patients	67.2	52.8	p<0.001
Incidence of transport to hospital (%)*	31.7 (47)	19.5 (37)	p<0.001
Status on arrival to hospital			
Incidence of arrival with ROSC (%)	24.3 (36)	15.1 (29)	p<0.001
Incidence of arrival with ongoing CPR (%)	7.4 (11)	4.1 (8)	p<0.001
Incidence of 24-hour survival (%) **	15.5 (23)	13.7 (24)	p<0.001
Incidence of survival (%) ***	8.0 (12)	7.8 (15)	p=0.42

GRR – German Resuscitation Registry – areas with good quality data, NorCAR – Norwegian Cardiac Arrest Registry, ROSC – return of spontaneous circulation, CPR - cardiopulmonary resuscitation, EMS – emergency medical service, PCI - Percutaneous Coronary Intervention.

* Declared dead/transport to hospital – missing 265 (1%) in GRR and 104 (1%) in NorCAR,

** 24-hour survival – missing 2273 (8%) in GRR and 195 (1%) in NorCAR

*** Survival – missing 1931 (7%) in GRR and 165 (1%) in NorCAR

The use of a mechanical chest compressions device was higher in NorCAR than in GRR (4020 of 13704 (29%) vs 3223 of 28786 (11%) respectively, p<0.001). For patients transported to hospital and arriving with ROSC or ongoing CPR, 1987 of 13571 (15%) of the

14

patients in GRR and 1079 of 4962 (22%) of the patients in NorCAR were transported directly to the PCI lab on arrival.

Utstein comparator group

The incidence of patients in the Utstein group was higher in GRR, but they constituted a smaller proportion of the EMS-treated population (14 vs 17 %). Bystander CPR was higher in NorCAR (1961 of 2274 (86%)) than in GRR (2726 of 4155 (66%)). For patients transported to hospital and arriving with ROSC or ongoing CPR, 879 of 3362 (26%) of the patients in GRR and 548 of 1502 (37%) of the patients in NorCAR were transported directly to the PCI lab on arrival. The incidence of prehospital ROSC and survival to 24-hours was higher in GRR (Table 4 and Figure 4), but the incidence of overall survival was higher in NorCAR.

Table 4: Outcome for the Utstein comparator group per 100,000 inhabitants

Utstein comparator group	GRR N=4155	NorCAR N= 2274	P-value
Incidence in the Utstein comparator group	9.7	8.8	p<0.001
Incidence of transport to hospital (%) *	7.8 (81)	6.2 (71)	p<0.001
Status on arrival to hospital			
Incidence of arrival to hospital with ROSC (%)	6.4 (66)	5.0 (57)	p<0.001
Incidence of arrival to hospital with ongoing CPR (%)	1.4 (15)	0.8 (9)	p<0.001

18 **DISCUSSION**

19
20
21 The incidence of cardiac arrest per 100,000 inhabitants is higher in GRR compared to
22
23 NorCAR. GRR reports a higher incidence of EMS treated patients, a higher incidence of
24
25 patients transported to the hospital and a higher incidence of patients arriving in the hospital
26
27 with ROSC. The overall incidence of survival is similar in both countries. For the Utstein
28
29 comparator group, the incidence of survival is marginally higher in NorCAR. Patient
30
31 characteristics in both countries, such as age and gender, confirms previous reports⁶.
32
33
34
35
36

37
38 Using registry data from two different countries, we encountered some challenges. A certain
39
40 amount of recoding of variables had to be done, notably using survival to hospital discharge
41
42 in GRR and 30-day survival in NorCAR. Both survival to discharge, and 30-day survival,
43
44 have been used interchangeably in other international studies, including the latest
45
46 recommendations for reporting⁹. Also, in a registry, it is not easy to verify the completeness
47
48 of cases²¹. Most EMS services in Europe have a paper-based reporting system, and there are
49
50 no electronically available patient charts to use as controls. Both GRR and NorCAR are
51
52 dependent on the attending EMS personnel remembering to submit a form after the event.
53
54 This form is then manually entered into the registry database by data managers.
55
56
57

58 16
59
60

1
2
3
4
5 Comparing a voluntary registry with a mandatory registry, we were worried about missing
6 information. In the latest published update on uniform reporting of cardiac arrest, the Utstein
7 reporting format, the authors stress the importance of reducing missing information⁹. We
8 found that the rate of missing information is overall higher in GRR, and the variable with the
9 highest missing rate is survival (7 %). Survival information is mostly missing from entire
10 hospitals, indicating that missing cases include both survivors and non-survivors. Due to GRR
11 being a voluntary registry, information on cardiac arrest cases is not available from the entire
12 country. Results are, however, comparable to overall results in yearly reports from GRR and
13 the data in this study are considered to be representable for all regions reporting to the
14 registry¹⁷.

24
25
26
27
28
29
30

31 Reporting the incidence of cardiac arrest is primarily done using the number of patients per
32 100,000 inhabitants in the population served by the EMS⁶⁻⁸. Survival, however, is often
33 presented as a proportion of the EMS treated patients. Percentages are presumed to be easier
34 to understand and make comparability with already published data more straightforward.
35 During the Covid-19 pandemic, healthcare professionals and the general public have become
36 more used to population incidence as a measurement, and we believe it is time for survival
37 after cardiac arrest to be published in this way. In 1993, Becker et al.²² published an analysis
38 on the relationship between reported incidence and survival rates and advised incidence and
39 not percentages. When there is more than a 3-fold difference in the incidence of EMS treated
40 patients, as reported in the latest EuReCa study,⁶ higher survival rates do not necessarily
41 represent better quality of care. The difference could be that a registry with a low survival
42 percentage is better at identifying all patients resuscitated by the EMS. Our study shows that
43 the incidence of survival is similar in GRR and NorCAR, but the incidence of included
44
45
46
47

51
52
53
54
55
56
57
58
59
60

1
2
3 patients is not. If we calculate the survival rate based on the number of patients resuscitated
4
5 by the EMS, Norway seems to have better survival (15%) than Germany (12%).
6
7
8
9

10 Differences in the incidence of cardiac arrest overall, and the EMS treated patients in
11
12 particular, could be due to differences in public health in general and cardiovascular health in
13
14 particular. According to the European Unions' statistics, cardiovascular disease deaths account
15
16 for 37% of deaths in Germany, but only 26% in Norway²³. Population density, geography and
17
18 placement of ambulances might also have an impact. Both countries adhere to European
19
20 guidelines for resuscitation,²⁴ but in Norway, withholding care in the prehospital setting is
21
22 more common.
23
24
25
26
27

28 Response interval is the time interval from a call is received at an EMCC to the first
29
30 ambulance arrives at the defined address. Response interval should ideally include the delay
31
32 until EMS personnel are at the patient side, but the latter time point remains elusive due to
33
34 manual registration. The extended response interval in Norway provides dispatchers more
35
36 time to help bystanders start CPR, connect and use a defibrillator, and is associated with a
37
38 significantly higher number of patients having been successfully resuscitated before EMS
39
40 arrival. On the downside, it probably also has a negative effect on survival^{25 26}. The narrow
41
42 distribution of response intervals in GRR (25- and 75-percentiles of 6 and 10 minutes)
43
44 compared with the broader distribution found in NorCAR (25- and 75-percentiles of 6 and 14
45
46 minutes) indicates differences caused by geography and population density. Extended
47
48 response intervals might also explain the lower incidence of EMS treated patients in Norway
49
50 as bystanders or EMS personnel perceive resuscitation as futile when the response interval is
51
52 prolonged.
53
54
55
56
57
58
59
60

1
2
3 The Utstein comparator group is a sub-group that enables comparison between countries⁹.
4
5 This sub-group has a more uniform treatment recommendation than the total population of
6
7 patients with OHCA and does not include cases with unknown delay from collapse. Our
8
9 results confirm that the differences between our countries also extends to this specific group.
10
11 Differences between countries in the Utstein comparator group have been shown in several
12
13 studies previously^{6 10 27}.
14
15
16
17
18

19 In Norway, all hospitals are state-owned, and the Norwegian Directory of Health issues
20
21 guidelines for treatment. Results from quality registries are published yearly, naming and
22
23 shaming hospitals and their adherence to guidelines²⁸. There is a bypass protocol for the
24
25 nearest University Hospital capable of performing PCI for cardiac arrest patients. If transport
26
27 duration is prolonged, there are guidelines for prehospital treatment, including thrombolysis.
28
29 In Norway, the in-hospital treatment after OHCA is standardised, but this is not the case in
30
31 most German hospitals. In 2019, the German Resuscitation Council started an initiative to
32
33 certify cardiac arrest centres, and GRR extended the benchmarking facilities for cardiac arrest
34
35 centres²⁹.
36
37
38
39
40
41

42 Several factors are associated with increased survival after OHCA; younger age, presumed
43
44 cardiac cause, shockable first rhythm, witnessed collapse, location of arrest in a public place,
45
46 bystander CPR, early shock by a defibrillator, a short time from collapse to arrival of EMS
47
48 and good post-resuscitation care including temperature control and PCI^{15 30}. Compared to
49
50 GRR, the patients in NorCAR are younger, witnessed collapse is more common and more
51
52 than four out of five receive bystander CPR. Compared to NorCAR, the patients in GRR more
53
54 often have presumed cardiac cause, initial rhythm is shockable, and the EMS's response
55
56 interval is shorter. There is a mix of factors associated with survival in both countries.
57
58
59
60

1
2
3
4
5 This study has helped us identify differences and similarities in the cardiac arrest registries in
6 Germany and Norway and identify potential confounders for future studies. In this
7
8 comparison, we cannot tease out the relative importance of factors associated with increased
9
10 survival, and in future studies, we should analyse individual cases using more sophisticated
11
12 statistical methods.
13
14
15
16
17
18

19 **Implication for the future**

20
21
22 Based on our findings, we recommend all nations make cardiac arrest a reportable condition.
23
24 Making reporting mandatory provides an opportunity to follow a patient through the
25
26 healthcare system and to evaluate how an intervention affects care, health, and cost.³¹ When
27
28 participation in a registry is voluntary, it is difficult to conclude that results are representative
29
30 for a larger population. If cardiac arrest is not a reportable condition, there is a greater risk
31
32 that EMS systems and hospitals deliberately do not participate because of fear that their level
33
34 of care is sub-optimal.
35
36
37
38
39
40
41

42 Treating and reporting many patients that do not survive will give a low survival rate, while
43
44 treating and reporting a low number of non-survivors will give a high survival rate. Reporting
45
46 inclusion and results as incidence per 100,000 inhabitants is essential if we wish to know the
47
48 burden of disease in a population, and it is a way of making results more comparable as
49
50 variation in how prehospital providers perceive futility and variable reporting practices will
51
52 have less impact on the overall reported survival.^{6-8 12}
53
54
55
56
57
58
59
60

CONCLUSION

This cross-sectional study shows the importance of comparing the incidence of survival based on the population served and not on the percentage of EMS treated patients. When comparing data from OHCA registries, especially when comparing survival, we recommend using incidence per 100,000 inhabitants, and we believe it is time to stop reporting survival as percentages.

We found that the EMS in Germany started CPR on a higher number of cardiac arrest patients, and the incidence of patients transported to the hospital and arriving with ROSC is higher than in NorCAR. We speculate that the difference in overall incidence and incidence of EMS treated patients is due to an interaction between response intervals, bystander CPR, age and EMS organisation. A multivariate analysis should be performed to better understand our findings.

LEGEND TO FIGURES

Figure 1: Flow of patients in the German Resuscitation Registry.

Figure 2: Flow of patients in the Norwegian Cardiac Arrest Registry.

Figure 3: All resuscitated patients included in the German and the Norwegian cardiac arrest registries per 100,000 inhabitants from 2015 and 2019. CPR - cardiopulmonary resuscitation, EMS – emergency medical personnel, ROSC – return of spontaneous circulation.

Figure 4: The Utstein comparator group. Incidence per 100,000. Utstein comparator group is cardiac arrest witnessed by a bystander and having a shockable rhythm. ROSC – return of spontaneous circulation.

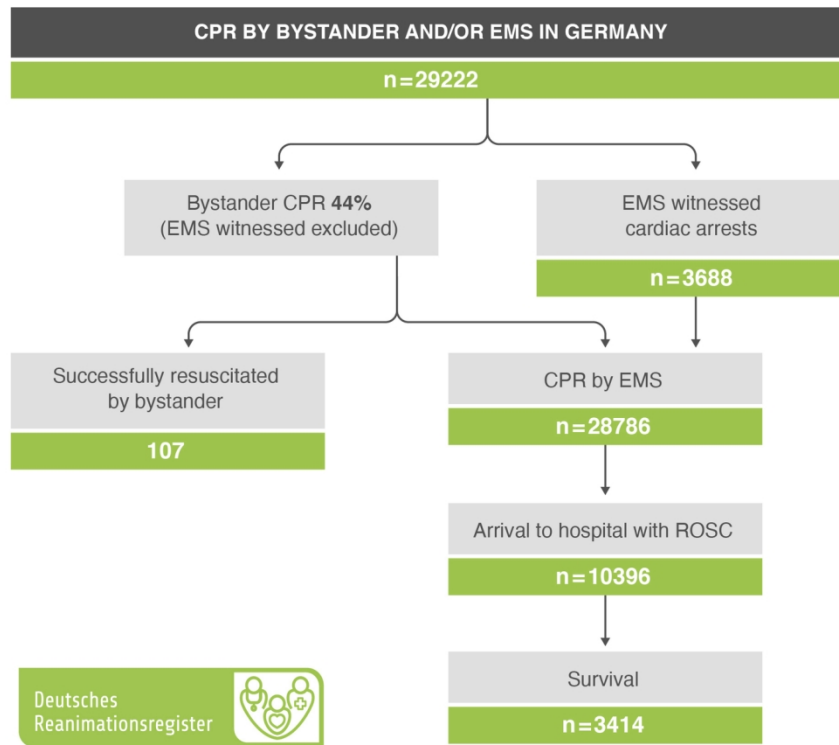

Figure 1: Flow of patients in the German Resuscitation Registry.

139x121mm (300 x 300 DPI)

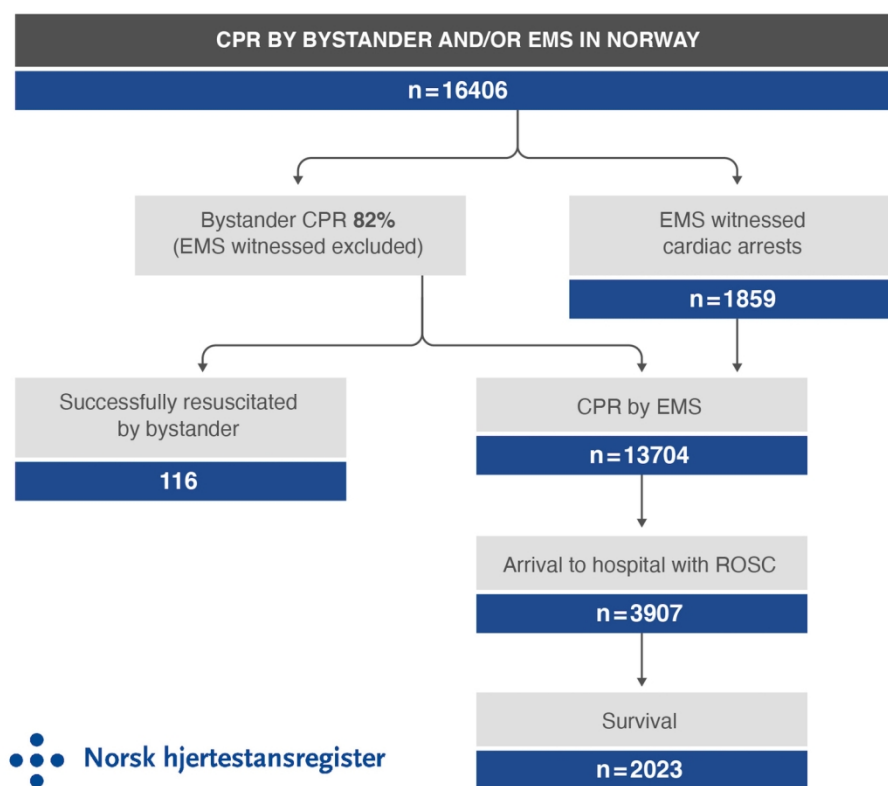

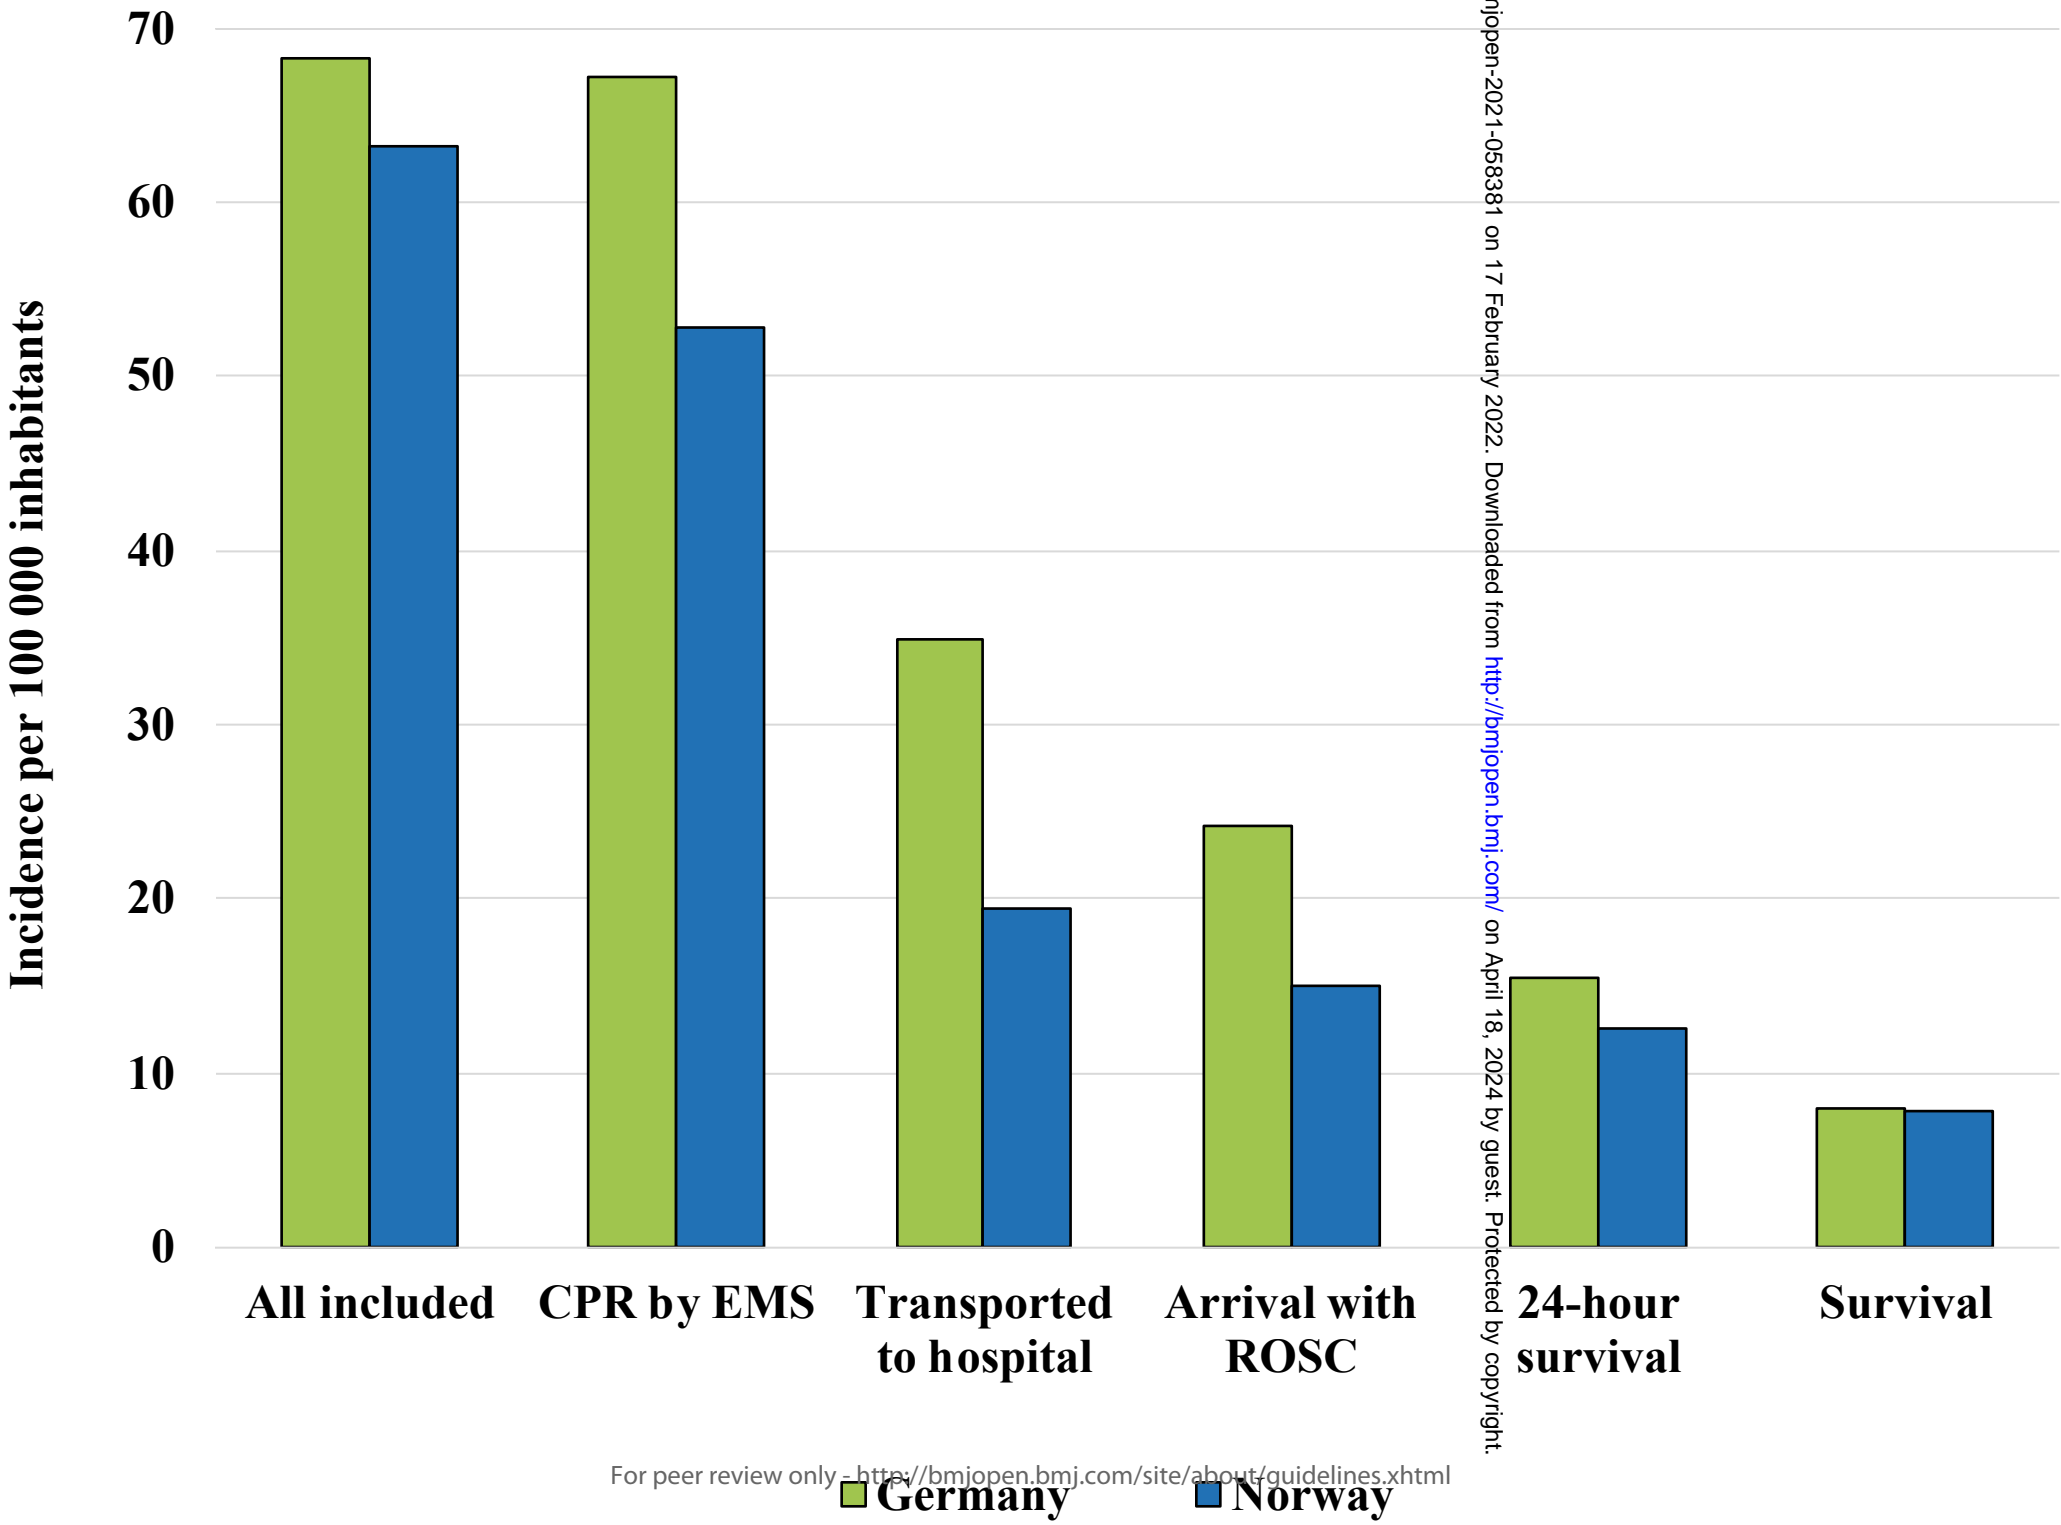

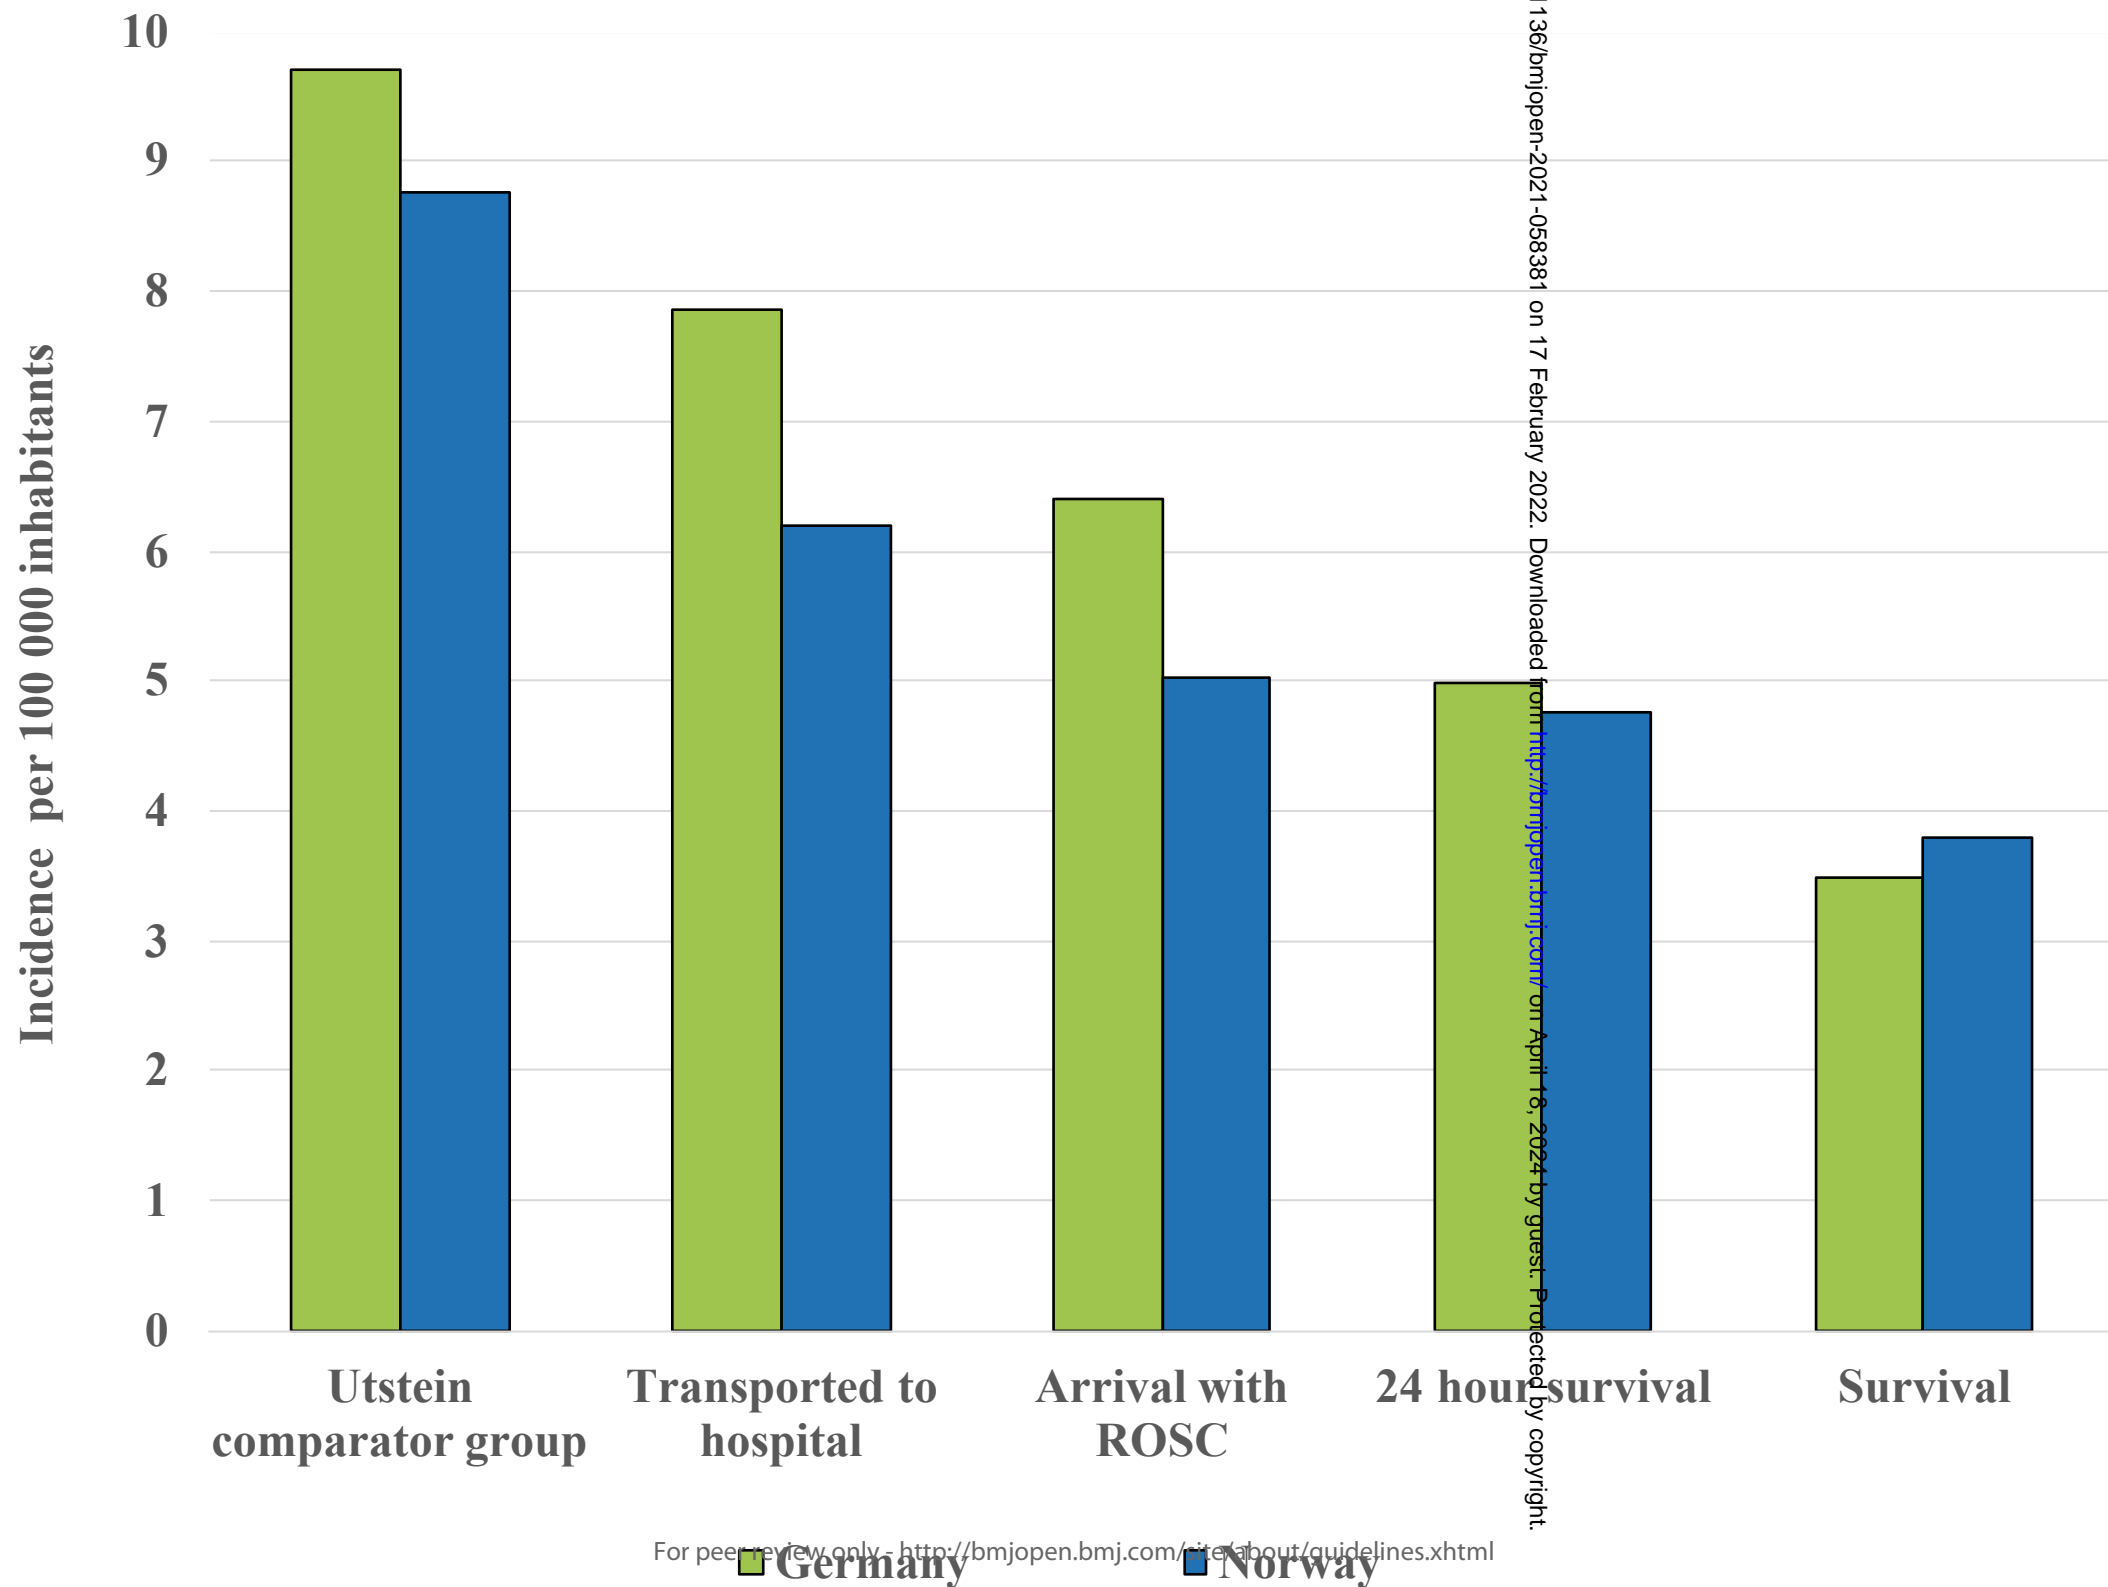

Figure 2: Flow of patients in the Norwegian Cardiac Arrest Registry.

139x127mm (300 x 300 DPI)

Reporting checklist for cross sectional study.

	Reporting Item	Page Number
Title and abstract		
Title	#1a Indicate the study's design with a commonly used term in the title or the abstract	1
Abstract	#1b Provide in the abstract an informative and balanced summary of what was done and what was found	3
Introduction		
Background / rationale	#2 Explain the scientific background and rationale for the investigation being reported	5
Objectives	#3 State specific objectives, including any prespecified hypotheses	5
Methods		
Study design	#4 Present key elements of study design early in the paper	5
Setting	#5 Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6-10
Eligibility criteria	#6a Give the eligibility criteria, and the sources and methods of selection of participants.	9
	#7 Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	9
Data sources / measurement	#8 For each variable of interest give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group. Give information separately for for exposed and unexposed groups if applicable.	8-9
Bias	#9 Describe any efforts to address potential sources of bias	16
Study size	#10 Explain how the study size was arrived at	n/a, all patients were included

1	Quantitative	#11	Explain how quantitative variables were handled in the	10-11
2	variables		analyses. If applicable, describe which groupings were chosen,	
3			and why	
4				
5				
6	Statistical	#12a	Describe all statistical methods, including those used to control	10-11
7	methods		for confounding	
8				
9				
10	Statistical	#12b	Describe any methods used to examine subgroups and	10-11
11	methods		interactions	
12				
13				
14	Statistical	#12c	Explain how missing data were addressed	n/a missing
15	methods			variables are
16				reported in
17				tables
18				
19				
20				
21	Statistical	#12d	If applicable, describe analytical methods taking account of	n/a
22	methods		sampling strategy	
23				
24	Statistical	#12e	Describe any sensitivity analyses	n/a
25	methods			
26				
27				
28	Results			
29				
30				
31	Participants	#13a	Report numbers of individuals at each stage of study—eg	Table 1-4
32			numbers potentially eligible, examined for eligibility, confirmed	
33			eligible, included in the study, completing follow-up, and	
34			analysed. Give information separately for for exposed and	
35			unexposed groups if applicable.	
36				
37				
38				
39	Participants	#13b	Give reasons for non-participation at each stage	n/a
40				
41	Participants	#13c	Consider use of a flow diagram	Figure 1a and
42				b
43				
44				
45	Descriptive data	#14a	Give characteristics of study participants (eg demographic,	11, Table 1
46			clinical, social) and information on exposures and potential	
47			confounders. Give information separately for exposed and	
48			unexposed groups if applicable.	
49				
50				
51				
52	Descriptive data	#14b	Indicate number of participants with missing data for each	Table 1-4
53			variable of interest	
54				
55				
56				
57				
58				
59				
60				

1	Outcome data	#15	Report numbers of outcome events or summary measures. Give information separately for exposed and unexposed groups if applicable.	Table 1-4
2				
3				
4				
5				
6	Main results	#16a	Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	n/a
7				
8				
9				
10				
11				
12				
13	Main results	#16b	Report category boundaries when continuous variables were categorized	n/a
14				
15				
16				
17	Main results	#16c	If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	n/a
18				
19				
20				
21	Other analyses	#17	Report other analyses done—e.g., analyses of subgroups and interactions, and sensitivity analyses	Table 2-4
22				
23				
24				
25	Discussion			
26				
27	Key results	#18	Summarise key results with reference to study objectives	16
28				
29	Limitations	#19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias.	16-17
30				
31				
32				
33				
34	Interpretation	#20	Give a cautious overall interpretation considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence.	17-19
35				
36				
37				
38				
39				
40	Generalisability	#21	Discuss the generalisability (external validity) of the study results	18-20
41				
42				
43				
44	Other			
45	Information			
46				
47	Funding	#22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	21
48				
49				
50				
51				
52
