Abstract

Objectives: Since 2009, China has introduced policies, principally targeting health professionals, to reduce caesarean section (CS) overuse. This study investigated changes to CS rates in 2008-2018, and factors associated with CS use during the period of transition from the one-to-two child policy era.

Design: We used births data from cross-sectional National Household Health Services Surveys in 2013 and 2018.

Setting: Population-based national survey

Participants: Women who had the last live birth within the five years before the survey

Primary outcome measure: Caesarean section rate

Results: Overall CS use increased from 40.9% in 2008 to 47.2% in 2014 with significant increase in rural areas and the western region, and slightly decreased to 45.2% in 2018 with the greatest decrease among nulliparous women. Maternal request for CS by urban nulliparous women decreased from 36.8% in 2008-2009 to 22.2% in 2016-2018, but this change was not statistically significant in rural areas. Advanced maternal age and place of birth (private hospital) were associated with CS use among nulliparous women in 2016-2018. The CS rate among multiparous women increased over time. Individual socio-economic factors associated with CS use among multiparous women.

Conclusions: The CS rate rise in China in 2008-2018 is attributable to increased use in rural areas and the less developed Western region. The population policy shift, alongside facility policies for unnecessary CS reduction, are likely factors in CS reduction in urban areas. The challenge remains to reduce unnecessary CS, at the same time as providing safe, universal access to CSs for women in need.

Strengths and limitations of this study

- This study used well-established population-based national survey data to examine the change of caesarean section rate in China by urban and rural areas, across regions and women's characteristics over the periods of population policy shift.
- This study provides unique insights into both mode of birth and whom households report proposed actual caesarean births.
- We are not able to conduct more sub-groups analysis such as previous caesarean section or others due to unavailable data.

Introduction

Globally, Caesarean Section (CS) rates are rising in all regions with one of fifth of live births being by CS in 2015.¹ Complex social, cultural, economic, and medical factors are known drivers of CS use. Overuse and underuse of CS represent simultaneous challenges for many health systems. Overuse of CS, where CS is performed without or on the basis of ambiguous medical indications has been associated with increased risk of maternal and newborn adverse outcomes and increased costs for health systems and individuals.^{2, 3} Meanwhile, the low use of CS implies limited accessibility to this life-saving procedures for women in need during childbirth.¹ The World Health Organization (WHO) Statement on Caesarean Section Rates suggests that CS rates at population level higher than 10% are not associated with reductions in maternal and newborn mortality rates, while every effort should be made to provide CS to women in need.⁴

China has witnessed a rapid increase in the use of CS since 1990s.⁵⁻⁸ According to the data from the National Household Health Services Surveys (NHHSS) in China, the CS rate increased from 19.2% in 2003 to 36.3% in 2011.⁶ This survey found that the CS rate in urban areas (46.8%) in 2011 was 1.4 times of that in rural areas, and the CS rate in 2011 was the highest in central region (44.7%), followed by eastern region (41.5%) and the lowest in less developed western region (25.0%). A recent study used the data from the National Maternal Near Miss Surveillance System (NMNMSS), and found a gradual decrease of CS rates from 45.3% in 2012 to 41.1% in 2016, particularly among nulliparous and multiparous births without a uterine scar, in correspondence with the relaxation of the only child policy in China.⁸ In this study, the authors also indicated that urban population were over-represented in the NMNMSS.

Many CSs in China are not medically indicated.⁹ There is evidence that individual, health system and socio-cultural factors are driving the use of CS.¹⁰ Women may request CS because of fear of labor pain, fear of risk and adverse outcomes of vaginal delivery, perceived convenience of CS for birth plan and control and perceived CS as a safe option for childbirth.¹⁰ In China, facility-based delivery is a national strategy to reduce risks of adverse outcomes for mothers and newborns. Almost all births occurred in health facilities by 2015. It has been argued that financial incentive and fear of malpractice may shape the preference of health professionals for performing CS in the hospital settings.^{10, 11} Since 2009, the Chinese government has increasingly introduced policies and strategies at national and local levels to restrict the use of unnecessary CS.⁸ These strategies largely targeted health professionals. They include revising clinical guideline to strict control of CS indications, strengthening training of midwifery care and audit of CS without medical indications, setting

1
2
3 facility CS rate targets and removing financial incentives for CS. Few experimental studies
4 have assessed how well these strategies work to optimize the use of CS.^{7, 8}
5
6

7 China has gradually relaxed family planning policy since 2013, with all families being allowed
8 and encouraged to have a second child in 2016. Advanced maternal age and previous CS
9 may indicate changes in obstetric risks, which raise the concerns on the need for and safety
10 of CS.^{12, 13} The aim of this study was to investigate changes to CS rates between 2008 and
11 2018, by urban and rural location, and across socio-economic regions in China. It sought to
12 examine maternal request for CS by the study periods, as well as demographic and socio-
13 economic factors associated with use of CS during the period of transition from the one-to-
14 two child policy era.

20 **Methods**

21 *Data source*

22
23 We used cross-sectional data obtained from National Household Health Services Surveys
24 (NHHSS) conducted in 2013 and 2018 by the Center for Health Statistics and Information of
25 the National Health Commission (NHC) of China (formerly the Ministry of Health). Each
26 survey employed the same three-stage, stratified, cluster random sampling procedure. At the
27 first stage, urban and rural location and socio-economic regions were used to classify cities
28 and counties into six groups: eastern urban, eastern rural, central urban, central rural,
29 western urban and western rural. Simple random sampling was used to select cities and
30 counties from each group. The random sample process was repeated for three times to
31 select the ones most close to the parameters (e.g. fertility rate, mortality rate and
32 demographic structure etc.) representing the general. Then five sub-districts or townships
33 were randomly selected from each city or county based on the rank of number of population.
34 Finally, three communities or villages from each sub-district or township were randomly
35 selected and all households in the selected sub-district or township were included in the
36 survey. In total, 93,613 households were included in the survey of 2013 and 94,074 in the
37 survey of 2018.

48

49 *Data collection*

50
51 The trained primary health workers administered face-to-face survey to each family member
52 in the sampled households using structured questionnaire. The questionnaires used in the
53 two surveys had a same structure and involved similar questions, which included the general
54 demographic and socio-economic characteristics of the sampled households and family
55 members, the utilization of and expenditures on health services. There is one section on the
56 childbirth that asked questions about the use of antenatal care, place of delivery, mode of
57
58
59
60

1
2
3 delivery and caesarean delivery for maternal request. We included women who had the last
4 live birth within the five years before the survey in this study.
5

6 7 *Data analysis* 8

9 The outcome measure was the percentage of births by CS. In the survey, the mode of
10 delivery was asked with the following question: "How did the birth take place: a) vaginal
11 delivery; b) caesarean section". If the answer was "caesarean section", the following
12 question was "Who was the most important person of proposing CS: a) myself; b) husband;
13 c) parent; d) doctor; e) others". We considered CS as a woman request in the analysis if the
14 woman choose the option "a (myself)".
15
16
17
18

19 We examined factors associated with the use of CS that included: maternal age; maternal
20 educational level; location of resident (urban, rural); living in different socio-economic region
21 (developed Eastern, less developed Central, least developed Western); health insurance
22 coverage; income quartile; parity, defined as the number of live births born by a woman; and
23 place of delivery, defined as type of health facility where the live birth occurred. There are
24 three basic health insurance schemes in China: Urban Employee Basic Health Insurance
25 (UEBMI), Urban Residents Basic Health Insurance (URBMI) and rural New Cooperative
26 Medical Scheme (NCMS). In recent years, URBMI was integrated with NCMS in some
27 provinces renamed as Urban and Rural Residents Basic Medical Insurance (URRBMI).
28 Overall, UEBMI provides better coverage for both inpatient and outpatient care compared to
29 URRBMI. In the analysis, we grouped URBMI, NCMS and URRBMI into one category as
30 "URRBMI", and other health insurances included free medical service scheme for special
31 sectors or labor insurance. Annual household income in the calendar year that preceded the
32 survey included savings and household expenditure on consumables during that year. We
33 generated income quartile by dividing household income by the number of individuals in the
34 household.

45 We investigated changes of CS rate in 2008-2018 by location of residents and across
46 different socio-economic regions. We also examined CS rate among nulliparous and
47 multiparous women by location and region. We studied change of women request for CS by
48 parity that the time period 2008-2018 was divided into 2008-2009, 2010-2012, 2013-2015
49 and 2016-2018. Chi-square test was used to test the difference by the study period. We
50 conducted bi-variate and multi-variate logistic regression analysis to study explanatory
51 variables associated with the use of CS for all and in stratification of urban and rural areas
52 and by socio-economic regions in 2008-2018. In addition, we also investigated factors
53 associated with the use of CS in 2016-2018 after universal two-child policy in China for all
54 and by nulliparous and multiparous women, by location and regions.

Patient and Public Involvement

This study is based on a secondary data analysis. No patient involved.

Results:

Total 23,053 women who had a live birth in the study period 2008-2018 were included in the analysis (Table 1). The distribution of maternal age was relatively similar by the study periods, and more than 60% of women were aged at 25-34 years. The proportion of women who received high school and professional school or higher and those who had two or more children increased over time. Few women had no health insurance coverage, and a vast majority of women had enrolled in URRBMI. In addition, there were more women in urban areas giving birth than women in rural areas observed in the period of 2016-2018. The distribution of women living region was relatively similar over time. The majority of women gave birth in general hospital (county or higher level hospital) and this proportion increased over time. The proportion of women giving birth in community and township health centers decreased in both urban and rural areas across different socio-economic regions (Supplementary files: Table 1). In the 2018 survey, fewer women reported choosing to give birth in a private hospital.

CS rate

Nationwide, the CS rate increased from 40.9% in 2008 to 47.2% in 2014. After the scale-up of the two-child policy, the CS rate slightly decreased; it was 45.2% in 2018. In urban areas, the CS rate slightly increased from 50.4% in 2008 to 52.3% in 2014, and then slightly decreased to 47.8% in 2018. However, in rural areas the CS rate had significantly increased from 33.1% in 2008 to 43.8% in 2015. In rural areas there was also a slight decrease after the relaxation of the one-child policy. The CS rate in rural areas was 41.2% in 2018 (Figure 1a). A similar trend was found across different socio-economic regions (Figure 1b). We observed a significant increase in CS rate from 28.1% in 2008 to 38.6% in 2018 in the least developed western region. In the stratification of urban and rural areas by regions, in 2008 the CS rates in urban areas in the eastern, central and western regions were 50.9%, 62.3% and 37.4% respectively. The difference of CS rate in urban areas by region became very small in 2018 (48.1% in eastern, 49.2% in central and 46.6% in western region). The CS rates in rural areas across all regions increased between 2008 and 2018. The CS rates in the eastern and central rural areas were higher or close to the rate in urban areas in these two regions (Supplementary file: Figure 1).

Around half of nulliparous women in urban areas gave birth by CS between 2008 and 2014, and the proportion in rural areas grew significantly from 33.3% in 2008 to 49.6% in 2015.

1
2
3 The CS rate among nulliparous women decreased rapidly in both urban (42.8% in 2018) and
4 rural areas (37.5% in 2018) after the universal two-child policy (Figure 2a). The CS rate
5 among multiparous women continued to increase from 35.3% in 2008 to 48.4% in 2018 with
6 similar trends in both urban and rural areas (Figure 2b). We found similar finding in terms of
7 the change of CS rate by parity across different socio-economic regions (Supplementary file:
8 Figure 2).
9
10
11
12

13 *Maternal request for CS*

14
15 We examined maternal request for CS by the study periods (Table 2). According to women's
16 self-report, the proportion of maternal request for CS among nulliparous women decreased
17 from 35.8% in 2008-2009 to 24.4% in 2016-2018 ($P<0.01$). In the stratification of residents
18 location, maternal request for CS significantly decreased in urban areas from 36.8% in 2008-
19 2009 to 22.2% in 2016-2018 ($p<0.01$), however the change in rural areas was not
20 statistically significant (from 33.5% in 2008-2009 to 29.4% in 2016-2018) (Supplementary
21 files: Table 2). Among multiparous women, around one third of women reported maternal
22 request for CS, and there was no significant change between 2008-2009 and 2016-2018.
23
24
25
26
27
28

29 In addition, the proportion of CS suggested by a doctor among nulliparous women increased
30 from 63.3% in 2008-2009 to 72.7% in 2016-2018 ($P<0.01$), and there was no significant
31 change of doctors' suggestion for CS among multiparous women by the study period. For
32 both nulliparous and multiparous women, there were few CSs proposed by women's
33 husband and others (Table 2).
34
35
36

37 *Factors associated with the use of CS*

38
39 Table 3 shows factors associated with the use of CS in China by urban and rural areas over
40 the study period of 2008-2018. After adjusting for all explanatory variables, the use of CS
41 was less common in urban areas in the survey of 2018 (OR 0.85, 95%CI 0.78-0.92)
42 compared to the survey of 2013, however, it was more common in rural areas (OR 1.30,
43 95%CI 1.19-1.41) in the survey of 2018. Advanced maternal age (≥ 35), having secondary
44 education or higher and giving birth at high level hospital or private hospital were significantly
45 associated with the use of CS in both urban and rural areas. In rural areas, women from the
46 highest income quartile were more likely to have CS (OR 1.69, 95%CI 1.47-1.95) compared
47 to women from the lowest quartile, and multiparous women were less likely to have CS (OR
48 0.80, 95%CI 0.73-0.88) than nulliparous women. While these differences were not
49 statistically significant in urban areas.
50
51
52
53
54
55
56

57 Across different socio-economic regions, the use of CS increased in western region in the
58 survey of 2018 (OR 1.10, 95% CI 1.00-1.22) than the survey of 2013, while this difference
59
60

was not statistically significant in eastern and central regions (Supplementary files: Table 3). Advanced maternal age (≥ 35) and giving birth at high level hospital or private hospital were associated with the use of CS in all regions. In central and western regions, women who lived in rural areas, were from low income quartile household and had more than one child were less likely to have CS.

Following the universal two-child policy in China (2016-2018), women in urban areas who were at advanced age (≥ 35), multiparous and gave birth at county or high level hospital or private hospital were more likely to have CS (Supplementary files: Table 4). In rural areas, in addition to maternal age and place of delivery, maternal education attainment and household income were also positively associated with the use of CS. Factors associated with the use of CS in eastern and central regions at the same study period were found similar in urban areas and those in western region were found similar in rural areas (Supplementary files: Table 5).

We examined the factors associated with the use of CS by parity in the era of two-child policy. We found that advanced maternal age (≥ 35) and births occurred at private hospital were significantly associated with the use of CS among nulliparous women after adjusting for all explanatory variables, while the association between the use of CS and other socio-economic factors was not statistically significant (Table 4). For multiparous women, women who were older, had higher education attainment, had health insurance coverage, were from wealthy household, lived in urban areas or eastern region and gave birth at higher level hospital or private hospital were more likely to have CS after adjusting for all explanatory variables (Table 4).

Discussion

Summary of key findings

In China, the CS rate increased between 2008 and 2015, which was, to a great extent, attributable to a rapid increase of the use of CS in rural areas and the least developed western region. After the scale-up of two-child policy, the CS rate slightly decreased in both urban and rural areas and across socio-economic regions, particularly among nulliparous women. The proportion of maternal request for CS decreased among nulliparous women in urban areas over time, however, this proportion decreased slightly in rural areas that 30% of women underwent CS due to maternal request for CS in 2016-2018. In the era of two-child policy, advanced maternal age and births occurred in a private hospital were associated with the use of CS among nulliparous women. The CS rate among multiparous women continued

1
2
3 to increase over time, and demographic and socio-economic factors were positively
4 associated with the use of CS among multiparous women.
5

6 7 *Strengths and limitations*

8
9 This study contributes to what is known about rates of CS in China, where most existing
10 studies are limited to a few hospitals or regions. It is a strength of this paper that with the
11 increase of population size and urbanization in China over the past two decades, the
12 National Household Health Services Survey adapted its sampling method in 2013 and
13 increased the sample size to achieve reliable representativeness of the general population
14 by urban and rural areas and across different socio-economic regions. It provides unique
15 insights into both mode of birth and whom households report proposed actual caesarean
16 births. However, several limitations in terms of data and analysis remain. First, all
17 information was based on women's reports, and the reasons for maternal request or doctor
18 suggestion for CS were not asked. We were not able to distinguish in this study how many
19 CSs performed were medically indicated. Second, women's history of pregnancy (e.g.
20 previous CS or others) was not available. We could not make a sub-group analysis on the
21 use of CS among women with or without uterine scar. Third, we could not separate the
22 effects of strategies to reduce unnecessary CS and the shift of the population policy on the
23 use of CS in China. That said, we did observe a slight decrease of CS rate in line with the
24 period of the universal two-child policy and the CS rate in urban areas and regions with a
25 high baseline rate had a moderate change over time (2008-2018). Thus the interpretation of
26 a decrease in CS rate following relaxation of the one-child policy should be made with
27 caution.

38

39 40 *Interpretations*

41
42 We observed a rapid decrease of CS rate among nulliparous women in both urban and rural
43 areas and across all regions in line with the period of universal two-child policy, which is
44 consistent with the findings in other studies.^{8,14} However, any causal association remains
45 speculative, not least because of the nuances within the one-child policy itself. In 1979,
46 China announced its family planning policy to strictly control population size. The policy
47 included rules of governing marriage, contraception, number of births and spacing where a
48 second child was permitted.¹⁵ The one child rule was strictest for urban residents and
49 employees of the government agencies. In rural areas, a second child was generally allowed
50 after five years, especially if the first born was a girl. Some ethnic minorities were permitted a
51 third child. With socio-economic development and change of demographic structure, the
52 Chinese government gradually relaxed the one-child policy over a decade with the entire
53 population encouraged to have a second child since 2016.¹⁶
54
55
56
57
58
59
60

1
2
3 The CS rate increased moderately in urban areas and the eastern and central regions, which
4 had a relatively high baseline CS rate. One plausible explanation is that this may be
5 attributable to the introduction of policies and strategies aiming to reverse the high CS rate
6 through a national top-down approach in China. Although, results of introducing
7 comprehensive interventions to mitigate unnecessary CSs are mixed in previous
8 studies.^{7,8,17,18}

13 We found that the CS rate increased dramatically in rural areas by all socio-economic
14 regions between 2008-2015. This rise may be associated with a significant increase in the
15 number of births occurring at secondary or higher-level (tertiary) hospitals, reflecting an
16 increase in availability and accessibility of these services in these areas. The Chinese
17 government had made strong commitment to reduce maternal and child mortality to achieve
18 Millennium Development Goal (MDG) targets by 2015.¹⁹ The main strategy was to promote
19 hospital delivery, particularly in rural and poor areas with largely financial support from the
20 central government and partly from the provincial government.¹⁹ In the context of deepening
21 China's health system reform, the national plan of further strengthening the hospital delivery
22 for rural women in 2009 highlighted to provide the financial compensation for hospital
23 delivery through rural health insurance (NCMS), the earmarked government fund and
24 medical assistance program for the poor women in order to reduce financial burden placed
25 on the households.²⁰ By 2014, hospital delivery in rural areas was almost universal. Across
26 countries, the shift from community to hospital births is known to result in an increase in CS
27 rates for medically indicated and non-medical reasons.²¹ In China, cross-sectional research
28 has shown that while tertiary hospitals have the highest rates of CS for ambiguous
29 indications (i.e. Non-reassuring foetal heart tracing; failure to progress), secondary level
30 hospitals report greater use of CS for maternal request.²²

42 *Implications for practice*

44 Previous studies report maternal request for CS as a contributor to a rapid increase of CS
45 rate in China,²²⁻²⁵ despite the validity of the concept being widely debated internationally. For
46 women who reportedly prefer CS, the most common reasons for their preference are fear of
47 labor pain, safer for their baby and for themselves.¹⁰ In this context, family members (e.g.
48 husband or parent) also supported this choice to avoid an adverse event, especially in the
49 context of one child in a family policy. Moreover, in our study around one third of nulliparous
50 women reported self-request for CS in the era of one-child policy. This proportion
51 significantly decreased in urban areas over time, which may be associated with the shift from
52 strict one child in a family in urban areas to universal two children, and promotion of vaginal
53 births in hospital settings. This change did not occur in rural areas.

1
2
3 Efforts to promote vaginal birth include midwifery care training (e.g. training more
4 professional midwives, establishment of standardized evaluation scheme of midwifery
5 practice etc.), pain relief for vaginal birth and informing women about benefits and risks of
6 different mode of delivery.²⁶ Other studies, largely in big cities and tertiary hospitals report
7 woman-centered pregnancy and childbirth care which includes provision of antenatal classes
8 to shape women's beliefs and confidence to childbirth, build connection and trust between
9 doctors, midwives and women as well as provide continuous supports during labor and
10 birth.^{14, 23, 27} At the same time, pharmacological and non-pharmacological options for labor
11 pain management have become available. However, the midwifery workforce in China is
12 insufficient. Quality of midwifery care can vary by hospitals, and urban-rural disparity in
13 midwife numbers and training is anecdotally reported. Lack of support during labor, lack of
14 pain relief and sub-optimal birth environment were reported as the main reasons that rural
15 women requested for CS.²⁸ Hence, strengthening midwifery care to improve women's
16 experience on childbirth, particularly in rural areas will be critical to optimize the use of CS in
17 China.

27 *Implications for further research*

29 In the era of two-child policy, only advanced maternal age and giving birth in a private
30 hospital were positively associated with the use of CS by nulliparous women. Since 2013
31 onward, the latest health-care delivery reform in China encouraged competition between
32 public and private hospitals, and set out the target of private hospitals sharing 20% of market
33 by 2015. The burgeoning of private hospital provision in China is driven by market forces,
34 with providers charges unregulated unless contracted by the basic health insurance
35 schemes.²⁹ Studies in other countries report much higher CSs rate in private hospitals due to
36 profit driven behavior.³⁰⁻³² It needs further study to have a better understanding on the use of
37 CS in private hospitals in China in order to propose evidence-based recommendations for
38 relevant policy development. In addition, we found that CS rate among multiparous women
39 continued to increase over time, especially in urban areas, which may be associated with the
40 increase of women who underwent repeat CS. Based on the NMNMSS data, Liang and
41 colleagues reported a high CS rate among multiparous women with a uterine scar and it was
42 unchanged over time.⁸ In China, repeat CS is often suggested and accepted for women with
43 a previous CS to mitigate the risk of uterine rupture or other adverse event, despite repeat
44 CS share similar risks. We can only speculate that there may be increasing referrals of
45 women with a previous CS to high level or specialty hospitals. The accessibility, functional
46 referral and affordability of such services as well as health outcomes, particularly for socio-
47 economic vulnerable women should be rigorous assessed in further research.

Conclusion

A rapid increase of CS rate in rural areas and less developed western region contributed to the increase of CS rate in China over the past decade. The population policy shift, alongside facility policies to limit the use of unnecessary CS, are likely factors contributing to the reduction of CS in urban areas. Strategies at system, organization and individual levels to mitigate unnecessary CSs should be continually strengthened, especially in rural areas and western region. Improving midwifery care will be fundamental to ensure safety and positive childbirth experience in the era of two-child in a family in China.

Research Ethics Approval Statement

We obtained the permission to access to data and conduct secondary data analysis.

Contributors

QL conceived and led the overall analysis and wrote the first manuscript draft. YGZ conducted the data analysis and commented on the manuscript. XJT and JZ contributed to the analysis and commented on the manuscript. CK contributed to the study concept and overall analysis and participated in the manuscript writing.

Conflicts of Interest

The authors declared no conflicts of interest.

6 Caesarean section rate in urban areas slightly decreased between 2008 and 2018, while it had increased
7 in rural areas. Across regions, a large increase occurred in less developed Western region.

60STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5-6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6
Bias	9	Describe any efforts to address potential sources of bias	5
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	6
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	6
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	7
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	17 (Table 1)
Outcome data	15*	Report numbers of outcome events or summary measures	7-8

1			
2	Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-
3			adjusted estimates and their precision (eg, 95% confidence
4			interval). Make clear which confounders were adjusted for and why
5			they were included
6			
7			(b) Report category boundaries when continuous variables were
8			categorized
9			
10			(c) If relevant, consider translating estimates of relative risk into
11			absolute risk for a meaningful time period
12	Other analyses	17	Report other analyses done—eg analyses of subgroups and
13			interactions, and sensitivity analyses
14			
15	Discussion		
16	Key results	18	Summarise key results with reference to study objectives
17			
18	Limitations	19	Discuss limitations of the study, taking into account sources of
19			potential bias or imprecision. Discuss both direction and magnitude
20			of any potential bias
21	Interpretation	20	Give a cautious overall interpretation of results considering
22			objectives, limitations, multiplicity of analyses, results from similar
23			studies, and other relevant evidence
24			
25	Generalisability	21	Discuss the generalisability (external validity) of the study results
26			
27	Other information		
28	Funding	22	Give the source of funding and the role of the funders for the
29			present study and, if applicable, for the original study on which the
30			present article is based
31			

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

Abstract

Objectives: Since 2009, China has introduced policies, principally targeting health professionals, to reduce caesarean section (CS) overuse. In 2016, China endorsed a universal two-child policy. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS. This study investigated changes to CS rates in 2008-2018, and factors associated with CS use during the period of transition from the one-to-two child policy era.

Design: We used births data from cross-sectional National Household Health Services Surveys in 2013 and 2018.

Setting: Population-based national survey

Participants: Women who had the last live birth within the five years before the survey

Primary outcome measure: Caesarean section rate

Results: Overall CS use increased from 40.9% in 2008 to 47.2% in 2014 with significant increase in rural areas and the western region, and slightly decreased to 45.2% in 2018 with the greatest decrease among nulliparous women. Maternal request for CS by urban nulliparous women decreased from 36.8% in 2008-2009 to 22.2% in 2016-2018, but this change was not statistically significant in rural areas. Maternal age over 35 years old (OR 2.40, 95%CI 1.76-3.31) and births occurred at private hospital (OR 1.52, 95%CI 1.25-1.86) were associated with CS use among nulliparous women in 2016-2018. The CS rate among multiparous women increased over time. Individual socio-economic factors associated with CS use among multiparous women.

Conclusions: The CS rate rise in China in 2008-2018 is attributable to increased use in rural areas and the less developed Western region. The population policy shift, alongside facility policies for unnecessary CS reduction, are likely factors in CS reduction in urban areas. The challenge remains to reduce unnecessary CS, at the same time as providing safe, universal access to CSs for women in need.

Strengths and limitations of this study

- This study used well-established population-based national survey data to examine the change of caesarean section rate in China by urban and rural areas, across regions and women's characteristics over the periods of population policy shift.
- This study could not separate the effects of strategies to reduce unnecessary CS and the shift of the population policy on the use of CS in China.
- We are not able to conduct more sub-groups analysis such as previous caesarean section or caesarean section with or without medical indications due to unavailable data.

Introduction

Globally, Caesarean Section (CS) rates are rising in all regions with one of fifth of live births being by CS in 2015.¹ Complex social, cultural, economic, and medical factors are known drivers of CS use.² Overuse and underuse of CS represent simultaneous challenges for many health systems. Overuse of CS, where CS is performed without or on the basis of ambiguous medical indications has been associated with increased risk of maternal and newborn adverse outcomes and increased costs for health systems and individuals.^{3, 4} Meanwhile, the low use of CS implies limited accessibility to this life-saving procedures for women in need during childbirth.¹ The World Health Organization (WHO) Statement on Caesarean Section Rates suggests that CS rates at population level higher than 10% are not associated with reductions in maternal and newborn mortality rates, while every effort should be made to provide CS to women in need.⁵

China has witnessed a rapid increase in the use of CS since 1990s.⁶⁻⁹ According to the data from the National Household Health Services Surveys in China, the CS rate increased from 19.2% in 2003 to 36.3% in 2011.⁷ Many CSs in China are not medically indicated.¹⁰ There is evidence that individual, health system and socio-cultural factors are driving the use of CS.¹¹ Women may request CS because of fear of labor pain, fear of risk and adverse outcomes of vaginal delivery, perceived convenience of CS for birth plan and control and perceived CS as a safe option for childbirth.¹¹ In China, facility-based delivery is a national strategy to reduce risks of adverse outcomes for mothers and newborns. Almost all births occurred in health facilities by 2015. It has been argued that financial incentive and fear of malpractice may shape the preference of health professionals for performing CS in the hospital settings.^{11, 12}

Since 2009, the Chinese government has increasingly introduced policies and strategies at national and local levels to restrict the use of unnecessary CS.⁹ These strategies largely targeted health professionals. They include revising clinical guideline to strict control of CS indications, strengthening training of midwifery care and audit of CS without medical indications, setting facility CS rate targets and removing financial incentives for CS. China has gradually relaxed family planning policy since 2013, with all families being allowed and encouraged to have a second child in 2016. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS.^{13, 14}

Recent studies that used data from the National Maternal Near Miss Surveillance System (NMNMSS) reported a moderate decrease of CS rate in some big cities, which coincided with the period of relaxation of the one-child policy between 2012-2016.^{8, 9} This decrease in

1
2
3 CS rate may be attributable to facility strategies to reduce the use of CS without medical
4 indications. However, the authors also acknowledged the limitation of NMNMS data in
5 over-representing urban populations. Little is known about trends of CS use in rural areas,
6 across regions at different stages of socio-economic development, nor how facility strategies
7 to mitigate unnecessary CS and the population policy shift have affected the use of CS in
8 these places.
9
10
11
12

13 This study used cross-sectional data from the National Household Health Services Survey
14 conducted in 2013 and 2018, which achieved reliable representativeness of the general
15 population by urban and rural areas and across socio-economic development regions. We
16 investigated changes to CS rates between 2008 and 2018, by urban and rural location, and
17 across socio-economic regions in China. It sought to examine maternal request for CS by
18 the study periods and by parity, as well as demographic and socio-economic factors
19 associated with use of CS during the period of transition from the one-to-two child policy era.

24

25 **Methods**

26 *Data source*

27 We obtained the permission to access to birth dataset from National Household Health
28 Services Surveys conducted in 2013 and 2018. Each survey employed the same three-
29 stage, stratified, cluster random sampling procedure. At the first stage, urban and rural
30 location and socio-economic regions were used to classify cities and counties into six groups:
31 eastern urban, eastern rural, central urban, central rural, western urban and western rural.
32 Simple random sampling was used to select cities and counties from each group. The
33 random sample process was repeated for three times to select the ones most close to the
34 parameters (e.g. fertility rate, mortality rate and demographic structure etc.) representing the
35 general. Then five sub-districts or townships were randomly selected from each city or
36 county based on the rank of number of population. Finally, three communities or villages
37 from each sub-district or township were randomly selected and all households in the
38 selected sub-district or township were included in the survey. In total, 93,613 households
39 were included in the survey of 2013 and 94,074 in the survey of 2018.
40
41
42
43
44
45
46
47
48
49

50 The trained primary health workers administered face-to-face survey to each family member
51 in the sampled households using structured questionnaire. The questionnaires used in the
52 two surveys had a same structure and involved similar questions, which included the general
53 demographic and socio-economic characteristics of the sampled households and family
54 members, the utilization of and expenditures on health services. There is one section on the
55 childbirth that asked questions about the use of antenatal care, place of delivery, mode of
56
57
58
59
60

1
2
3 delivery and caesarean delivery for maternal request. We included women who had the last
4 live birth within the five years before the survey in this study to avoid overrepresentation of
5 women who have one more child.
6
7

8 *Measures*

9
10 The outcome measure was the percentage of births by CS. In the survey, the mode of
11 delivery was asked with the following question: "How did the birth take place: a) vaginal
12 delivery; b) caesarean section". If the answer was "caesarean section", the following
13 question was "Who was the most important person of proposing CS: a) myself; b) husband;
14 c) parent; d) doctor; e) others". We considered CS as a woman request in the analysis if the
15 woman choose the option "a (myself)".
16
17
18
19

20
21 We examined demographic and socio-economic factors associated with the use of CS that
22 included: maternal age (<25, 25-34, ≥35); maternal educational level (illiterate or primary
23 school, secondary school, high school/professional school or higher); location of resident
24 (urban, rural); living in different socio-economic region (developed Eastern, less developed
25 Central, least developed Western); health insurance coverage; income quartile; parity,
26 defined as the number of live births born by a woman; and place of delivery, defined as type
27 of health facility where the live birth occurred (county or higher level hospital, maternal and
28 child health hospital, township/community health center, private hospital). There are three
29 basic health insurance schemes in China: Urban Employee Basic Health Insurance (UEBMI),
30 Urban Residents Basic Health Insurance (URBMI) and rural New Cooperative Medical
31 Scheme (NCMS). In recent years, URBMI was integrated with NCMS in some provinces
32 renamed as Urban and Rural Residents Basic Medical Insurance (URRBMI). Overall,
33 UEBMI provides better coverage for both inpatient and outpatient care compared to
34 URRBMI. In the analysis, we grouped URBMI, NCMS and URRBMI into one category as
35 "URRBMI". Health insurance coverage was grouped into: none coverage, UEBMI, URRBMI
36 and others (including free medical service scheme for special sectors or labor insurance).
37 Annual household income in the calendar year that preceded the survey included savings
38 and household expenditure on consumables during that year. We generated income quartile
39 by dividing household income by the number of individuals in the household, which reflected
40 lowest income group (quartile 1), low income group (quartile 2), middle income group
41 (quartile 3) and high income group (quartile 4).

55 *Data analysis*

56
57 We investigated changes of CS rate in 2008-2018 by urban and rural areas and across
58 different socio-economic regions. We also examined CS rate among nulliparous and
59
60

1
2
3 multiparous women by location and region in the study periods. We studied change of
4 women request for CS by parity that the time period 2008-2018 was divided into 2008-2009,
5 2010-2012, 2013-2015 and 2016-2018. Chi-square test was used to test the difference by
6 the study period. We conducted bi-variate and multi-variate logistic regression analysis to
7 study explanatory variables associated with the use of CS for all and in stratification of urban
8 and rural areas and by socio-economic regions in 2008-2018. In addition, we stratified data
9 in 2016-2018 to study demographic and socio-economic factors associated with the use of
10 CS after universal two-child policy in China for all and by nulliparous and multiparous women,
11 by location and regions.

12 **Ethical statement, patient and public involvement**

13
14 This study is based on a secondary data analysis. The research team obtained the approval
15 of the Center for Health Statistics and Information of the National Health Commission (NHC)
16 of China (formerly the Ministry of Health) to access to de-identified birth dataset. No patient
17 involved. Approval from an ethics committee was not required.

18 **Results:**

19
20 Total 23,053 women who had a live birth in the study period 2008-2018 were included in the
21 analysis (Table 1). The distribution of maternal age was relatively similar by the study
22 periods, and more than 60% of women were aged at 25-34 years. The proportion of women
23 who received high school and professional school or higher and those who had two or more
24 children increased over time. Few women had no health insurance coverage, and a vast
25 majority of women had enrolled in URRBMI. In addition, there were more women in urban
26 areas giving birth than women in rural areas observed in the period of 2016-2018. The
27 distribution of women living region was relatively similar over time. The majority of women
28 gave birth in general hospital (county or higher level hospital) and this proportion increased
29 over time. The proportion of women giving birth in community and township health centers
30 decreased in both urban and rural areas across different socio-economic regions
31 (Supplementary files: Table 1). In the 2018 survey, fewer women reported choosing to give
32 birth in a private hospital.

33 *CS rate*

34
35 Nationwide, the overall CS rate increased from 40.9% in 2008 to 47.2% in 2014. After the
36 scale-up of the two-child policy, the CS rate slightly decreased; it was 45.2% in 2018.

37 1) CS rate by urban and rural areas and across regions

1
2
3 In urban areas, the CS rate slightly increased from 50.4% in 2008 to 52.3% in 2014, and
4 then slightly decreased to 47.8% in 2018. However, in rural areas the CS rate had
5 significantly increased from 33.1% in 2008 to 43.8% in 2015. In rural areas there was also a
6 slight decrease after the relaxation of the one-child policy. The CS rate in rural areas was
7 41.2% in 2018 (Figure 1a). A similar trend was found across different socio-economic
8 regions (Figure 1b). We observed a significant increase in CS rate from 28.1% in 2008 to
9 38.6% in 2018 in the least developed western region. In the stratification of urban and rural
10 areas by regions, in 2008 the CS rates in urban areas in the eastern, central and western
11 regions were 50.9%, 62.3% and 37.4% respectively. The difference of CS rate in urban
12 areas by region became very small in 2018 (48.1% in eastern, 49.2% in central and 46.6% in
13 western region). The CS rates in rural areas across all regions increased between 2008 and
14 2018. The CS rates in the eastern and central rural areas were higher or close to the rate in
15 urban areas in these two regions (Supplementary file: Figure 1).

24 2) CS rate by parity

26 Around half of nulliparous women in urban areas gave birth by CS between 2008 and 2014,
27 and the proportion in rural areas grew significantly from 33.3% in 2008 to 49.6% in 2015.
28 The CS rate among nulliparous women decreased rapidly in both urban (42.8% in 2018) and
29 rural areas (37.5% in 2018) after the universal two-child policy (Figure 2a). The CS rate
30 among multiparous women continued to increase from 35.3% in 2008 to 48.4% in 2018 with
31 similar trends in both urban and rural areas (Figure 2b). We found similar finding in terms of
32 the change of CS rate by parity across different socio-economic regions (Supplementary file:
33 Figure 2).

39 *Maternal request for CS*

41 We examined maternal request for CS by the study periods (Table 2). According to women's
42 self-report, the proportion of maternal request for CS among nulliparous women decreased
43 from 35.8% in 2008-2009 to 24.4% in 2016-2018 ($P<0.01$). In the stratification of residents
44 location, maternal request for CS significantly decreased in urban areas from 36.8% in 2008-
45 2009 to 22.2% in 2016-2018 ($p<0.01$), however the change in rural areas was not
46 statistically significant (from 33.5% in 2008-2009 to 29.4% in 2016-2018) (Supplementary
47 files: Table 2). Among multiparous women, around one third of women reported maternal
48 request for CS, and there was no significant change between 2008-2009 and 2016-2018.

49 In addition, the proportion of CS suggested by a doctor among nulliparous women increased
50 from 63.3% in 2008-2009 to 72.7% in 2016-2018 ($P<0.01$), and there was no significant
51 change of doctors' suggestion for CS among multiparous women by the study period. For
52
53
54
55
56
57
58
59
60

1
2
3 both nulliparous and multiparous women, there were few CSs proposed by women's
4 husband and others (Table 2).
5

6 *Demographic and socio-economic factors associated with the use of CS*

7 8 9 1) In the study period of 2008-2018

10
11
12 Table 3 shows factors associated with the use of CS in China by urban and rural areas over
13 the study period of 2008-2018. After adjusting for all explanatory variables, the use of CS
14 was less common in urban areas in the survey of 2018 (OR 0.85, 95%CI 0.78-0.92)
15 compared to the survey of 2013, however, it was more common in rural areas (OR 1.30,
16 95%CI 1.19-1.41) in the survey of 2018. Advanced maternal age (≥ 35), having secondary
17 education or higher and giving birth at high level hospital or private hospital were significantly
18 associated with the use of CS in both urban and rural areas. In rural areas, women from the
19 highest income quartile were more likely to have CS (OR 1.69, 95%CI 1.47-1.95) compared
20 to women from the lowest quartile, and multiparous women were less likely to have CS (OR
21 0.80, 95%CI 0.73-0.88) than nulliparous women. While these differences were not
22 statistically significant in urban areas.
23
24
25
26
27
28
29

30
31 Across different socio-economic regions, the use of CS increased in western region in the
32 survey of 2018 (OR 1.10, 95% CI 1.00-1.22) than the survey of 2013, while this difference
33 was not statistically significant in eastern and central regions (Supplementary files: Table 3).
34 Advanced maternal age (≥ 35) and giving birth at high level hospital or private hospital were
35 associated with the use of CS in all regions. In central and western regions, women who
36 lived in rural areas, were from low income quartile household and had more than one child
37 were less likely to have CS.
38
39
40
41

42 2) In the study period of 2016-2018

43
44 Following the universal two-child policy in China (2016-2018), women in urban areas who
45 were at advanced age (≥ 35), multiparous and gave birth at county or high level hospital or
46 private hospital were more likely to have CS (Supplementary files: Table 4). In rural areas, in
47 addition to maternal age and place of delivery, maternal education attainment and household
48 income were also positively associated with the use of CS. Factors associated with the use
49 of CS in eastern and central regions at the same study period were found similar in urban
50 areas and those in western region were found similar in rural areas (Supplementary files:
51 Table 5).
52
53
54
55
56

57 We examined the factors associated with the use of CS by parity in the era of two-child
58 policy. We found that advanced maternal age (≥ 35) and births occurred at private hospital
59
60

1
2
3 were significantly associated with the use of CS among nulliparous women after adjusting for
4 all explanatory variables, while the association between the use of CS and other socio-
5 economic factors was not statistically significant (Table 4). For multiparous women, women
6 who were older, had higher education attainment, had health insurance coverage, were from
7 wealthy household, lived in urban areas or eastern region and gave birth at higher level
8 hospital or private hospital were more likely to have CS after adjusting for all explanatory
9 variables (Table 4).
10
11
12
13

14 **Discussion**

15 *Summary of key findings*

16
17
18 In China, the CS rate increased between 2008 and 2015, which was, to a great extent,
19 attributable to a rapid increase of the use of CS in rural areas and the least developed
20 western region. After the scale-up of two-child policy, the CS rate slightly decreased in both
21 urban and rural areas and across socio-economic regions, particularly among nulliparous
22 women. The proportion of maternal request for CS decreased among nulliparous women in
23 urban areas over time, however, this proportion decreased slightly in rural areas that 30% of
24 women underwent CS due to maternal request for CS in 2016-2018. In the era of two-child
25 policy, advanced maternal age and births occurred in a private hospital were associated with
26 the use of CS among nulliparous women. The CS rate among multiparous women continued
27 to increase over time, and demographic and socio-economic factors were positively
28 associated with the use of CS among multiparous women.

37 *Strengths and limitations*

38
39 This study contributes to what is known about rates of CS in China, where most existing
40 studies are limited to a few hospitals or regions. It is a strength of this paper that with the
41 increase of population size and urbanization in China over the past two decades, the
42 National Household Health Services Survey adapted its sampling method in 2013 and
43 increased the sample size to achieve reliable representativeness of the general population
44 by urban and rural areas and across different socio-economic regions. It provides unique
45 insights into both mode of birth and whom households report proposed actual caesarean
46 births. However, several limitations in terms of data and analysis remain. First, all
47 information was based on women's reports, and the reasons for maternal request or doctor
48 suggestion for CS were not asked. We were not able to distinguish in this study how many
49 CSs performed were medically indicated. Second, women's history of pregnancy (e.g.
50 previous CS or others) was not available. We could not make a sub-group analysis on the
51 use of CS among women with or without uterine scar. Third, we could not separate the
52
53
54
55
56
57
58
59
60

1
2
3 effects of strategies to reduce unnecessary CS and the shift of the population policy on the
4 use of CS in China. That said, we did observe a slight decrease of CS rate in line with the
5 period of the universal two-child policy and the CS rate in urban areas and regions with a
6 high baseline rate had a moderate change over time (2008-2018). Thus the interpretation of
7 a decrease in CS rate following relaxation of the one-child policy should be made with
8 caution.
9
10
11
12

13 *Interpretations*

14
15 We observed a rapid decrease of CS rate among nulliparous women in both urban and rural
16 areas and across all regions in line with the period of universal two-child policy, which is
17 consistent with the findings in other studies.^{9,15} However, any causal association remains
18 speculative, not least because of the nuances within the one-child policy itself. In 1979,
19 China announced its family planning policy to strictly control population size. The policy
20 included rules of governing marriage, contraception, number of births and spacing where a
21 second child was permitted.¹⁶ The one child rule was strictest for urban residents and
22 employees of the government agencies. In rural areas, a second child was generally allowed
23 after five years, especially if the first born was a girl. Some ethnic minorities were permitted a
24 third child. With socio-economic development and change of demographic structure, the
25 Chinese government gradually relaxed the one-child policy over a decade with the entire
26 population encouraged to have a second child since 2016.¹⁷
27
28
29
30
31
32
33
34

35 The CS rate decreased moderately in urban areas and the eastern and central regions,
36 which had a relatively high baseline CS rate. One plausible explanation is that this may be
37 attributable to the introduction of policies and strategies aiming to reverse the high CS rate
38 through a national top-down approach in China. Although, results of introducing
39 comprehensive interventions to mitigate unnecessary CSs are mixed in previous studies.^{8,9,18}
40
41
42
43

44 We found that the CS rate increased dramatically in rural areas by all socio-economic
45 regions between 2008-2015. This rise may be associated with a significant increase in the
46 number of births occurring at secondary or higher-level (tertiary) hospitals, reflecting an
47 increase in availability and accessibility of these services in these areas. The Chinese
48 government had made strong commitment to reduce maternal and child mortality to achieve
49 Millennium Development Goal (MDG) targets by 2015.¹⁹ The main strategy was to promote
50 hospital delivery, particularly in rural and poor areas with largely financial support from the
51 central government and partly from the provincial government.¹⁹ In the context of deepening
52 China's health system reform, the national plan of further strengthening the hospital delivery
53 for rural women in 2009 highlighted to provide the financial compensation for hospital
54 delivery through rural health insurance (NCMS), the earmarked government fund and
55
56
57
58
59
60

1
2
3 medical assistance program for the poor women in order to reduce financial burden placed
4 on the households.²⁰ By 2014, hospital delivery in rural areas was almost universal. Across
5 countries, the shift from community to hospital births is known to result in an increase in CS
6 rates for medically indicated and non-medical reasons.²¹ In China, cross-sectional research
7 has shown that while tertiary hospitals have the highest rates of CS for ambiguous
8 indications (i.e. Non-reassuring foetal heart tracing; failure to progress), secondary level
9 hospitals report greater use of CS for maternal request.²²
10
11
12
13
14

15 *Implications for practice*

16
17 Previous studies report maternal request for CS as a contributor to a rapid increase of CS
18 rate in China,²²⁻²⁵ despite the validity of the concept being widely debated internationally. For
19 women who reportedly prefer CS, the most common reasons for their preference are fear of
20 labor pain, safer for their baby and for themselves.¹¹ In this context, family members (e.g.
21 husband or parent) also supported this choice to avoid an adverse event, especially in the
22 context of one child in a family policy. Moreover, in our study around one third of nulliparous
23 women reported self-request for CS in the era of one-child policy. This proportion
24 significantly decreased in urban areas over time, which may be associated with the shift from
25 strict one child in a family in urban areas to universal two children, and promotion of vaginal
26 births in hospital settings. This change did not occur in rural areas, which indicate the needs
27 of strengthening quality of maternity care including services delivery and women's
28 experience in rural areas.
29
30
31
32
33
34
35

36
37 Efforts to promote vaginal birth in China included midwifery care training (e.g. training more
38 professional midwives, establishment of standardized evaluation scheme of midwifery
39 practice etc.), pain relief for vaginal birth and informing women about benefits and risks of
40 different mode of delivery.²⁶ Other studies, largely in big cities and tertiary hospitals report
41 woman-centered pregnancy and childbirth care which includes provision of antenatal classes
42 to shape women's beliefs and confidence to childbirth, build connection and trust between
43 doctors, midwives and women as well as provide continuous supports during labor and
44 birth.^{15, 23, 27} At the same time, pharmacological and non-pharmacological options for labor
45 pain management have become available. However, the midwifery workforce in China is
46 insufficient. Quality of midwifery care can vary by hospitals, and urban-rural disparity in
47 midwife numbers and training is anecdotally reported. Lack of support during labor, lack of
48 pain relief and sub-optimal birth environment were reported as the main reasons that rural
49 women requested for CS.²⁸ Hence, strengthening midwifery care to improve women's
50 experience on childbirth, particularly in rural areas will be critical to optimize the use of CS in
51 China.

Implications for further research

In the era of two-child policy, only advanced maternal age and giving birth in a private hospital were positively associated with the use of CS by nulliparous women. Since 2013 onward, the latest health-care delivery reform in China encouraged competition between public and private hospitals, and set out the target of private hospitals sharing 20% of market by 2015. The burgeoning of private hospital provision in China is driven by market forces, with providers charges unregulated unless contracted by the basic health insurance schemes.²⁹ Studies in other countries report much higher CSs rate in private hospitals due to profit driven behavior.³⁰⁻³² It needs further study to have a better understanding on the use of CS in private hospitals in China in order to propose evidence-based recommendations for relevant policy development. In addition, we found that CS rate among multiparous women continued to increase over time, especially in urban areas, which may be associated with the increase of women who underwent repeat CS. Based on the NMNMSS data, Liang and colleagues reported a high CS rate among multiparous women with a uterine scar and it was unchanged over time.⁹ In China, repeat CS is often suggested and accepted for women with a previous CS to mitigate the risk of uterine rupture or other adverse event, despite repeat CS share similar risks. We can only speculate that there may be increasing referrals of women with a previous CS to high level or specialty hospitals. The accessibility, functional referral and affordability of such services as well as health outcomes, particularly for socio-economic vulnerable women should be rigorous assessed in further research.

Conclusion

A rapid increase of CS rate in rural areas and less developed western region contributed to the increase of CS rate in China over the past decade. The population policy shift, alongside facility policies to limit the use of unnecessary CS, are likely factors contributing to the reduction of CS in urban areas. Strategies at system, organization and individual levels to mitigate unnecessary CSs should be continually strengthened, especially in rural areas and western region. Improving midwifery care will be fundamental to ensure safety and positive childbirth experience in the era of two-child in a family in China.

Research Ethics Approval Statement

We obtained the permission to access to de-identified birth dataset. No patient was involved, and thus an approval from an ethics committee was not required.

Abstract

Objectives: Since 2009, China has introduced policies, principally targeting health professionals, to reduce caesarean section (CS) overuse. In 2016, China endorsed a universal two-child policy. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS. This study investigated changes to CS rates in 2008-2018, and factors associated with CS use during the period of transition from the one-to-two child policy era.

Design: We used births data from cross-sectional National Household Health Services Surveys in 2013 and 2018.

Setting: Population-based national survey

Participants: Women who had the last live birth within the five years before the survey

Primary outcome measure: Caesarean section rate

Results: Overall CS use increased from 40.9% in 2008 to 47.2% in 2014 with significant increase in rural areas and the western region, and slightly decreased to 45.2% in 2018 with the greatest decrease among nulliparous women. Maternal request for CS by urban nulliparous women decreased from 36.8% in 2008-2009 to 22.2% in 2016-2018, but this change was not statistically significant in rural areas. Advanced maternal age over 35 years old (OR 2.40, 95%CI 1.76-3.31) and place of births occurred at (private hospital)(OR 1.52, 95%CI 1.25-1.86) were associated with CS use among nulliparous women in 2016-2018. The CS rate among multiparous women increased over time. Individual socio-economic factors associated with CS use among multiparous women.

Conclusions: The CS rate rise in China in 2008-2018 is attributable to increased use in rural areas and the less developed Western region. The population policy shift, alongside facility policies for unnecessary CS reduction, are likely factors in CS reduction in urban areas. The challenge remains to reduce unnecessary CS, at the same time as providing safe, universal access to CSs for women in need.

Strengths and limitations of this study

- This study used well-established population-based national survey data to examine the change of caesarean section rate in China by urban and rural areas, across regions and women's characteristics over the periods of population policy shift.
- ~~This study provides unique insights into both mode of birth and whom households report proposed actual caesarean births.~~
- ~~This study could not separate the effects of strategies to reduce unnecessary CS and the shift of the population policy on the use of CS in China.~~
- We are not able to conduct more sub-groups analysis such as previous caesarean section or ~~others caesarean section with or without medical indications~~ due to unavailable data.

Introduction

Globally, Caesarean Section (CS) rates are rising in all regions with one of fifth of live births being by CS in 2015.¹ Complex social, cultural, economic, and medical factors are known drivers of CS use.² Overuse and underuse of CS represent simultaneous challenges for many health systems. Overuse of CS, where CS is performed without or on the basis of ambiguous medical indications has been associated with increased risk of maternal and newborn adverse outcomes and increased costs for health systems and individuals.^{2,3,4} Meanwhile, the low use of CS implies limited accessibility to this life-saving procedures for women in need during childbirth.¹ The World Health Organization (WHO) Statement on Caesarean Section Rates suggests that CS rates at population level higher than 10% are not associated with reductions in maternal and newborn mortality rates, while every effort should be made to provide CS to women in need.⁵

China has witnessed a rapid increase in the use of CS since 1990s.⁶⁵⁻⁹⁸ According to the data from the National Household Health Services Surveys (NHSS) in China, the CS rate increased from 19.2% in 2003 to 36.3% in 2011.^{6,7} Many CSs in China are not medically indicated.¹⁰⁹ There is evidence that individual, health system and socio-cultural factors are driving the use of CS.¹⁰¹ Women may request CS because of fear of labor pain, fear of risk and adverse outcomes of vaginal delivery, perceived convenience of CS for birth plan and control and perceived CS as a safe option for childbirth.¹⁰¹ In China, facility-based delivery is a national strategy to reduce risks of adverse outcomes for mothers and newborns. Almost all births occurred in health facilities by 2015. It has been argued that financial incentive and fear of malpractice may shape the preference of health professionals for performing CS in the hospital settings.^{101, 124}

Since 2009, the Chinese government has increasingly introduced policies and strategies at national and local levels to restrict the use of unnecessary CS.⁹⁸ These strategies largely targeted health professionals. They include revising clinical guideline to strict control of CS indications, strengthening training of midwifery care and audit of CS without medical indications, setting facility CS rate targets and removing financial incentives for CS. China has gradually relaxed family planning policy since 2013, with all families being allowed and encouraged to have a second child in 2016. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS.^{13, 14}

Recent studies that used data from the National Maternal Near Miss Surveillance System (NMNMS) reported a moderate decrease of CS rate in some big cities, which coincided with the period of relaxation of the one-child policy between 2012-2016.^{8, 9} This decrease in

CS rate may be attributable to facility strategies to reduce the use of CS without medical indications. However, the authors also acknowledged the limitation of NMNMSS data in over-representing urban populations. Little is known about trends of CS use in rural areas, across regions at different stages of socio-economic development, nor how facility strategies to mitigate unnecessary CS and the population policy shift have affected the use of CS in these places.

~~The~~ This study used cross-sectional data from the National Household Health Services Survey conducted in 2013 and 2018, which achieved reliable representativeness of the general population by urban and rural areas and across socio-economic development regions. ~~aim of this study was to~~ We investigated changes to CS rates between 2008 and 2018, by urban and rural location, and across socio-economic regions in China. It sought to examine maternal request for CS by the study periods and by parity, as well as demographic and socio-economic factors associated with use of CS during the period of transition from the one-to-two child policy era.

Methods

Data source

We ~~obtained the permission used to access to birth dataset cross-sectional data obtained~~ from National Household Health Services Surveys (NHHSS) conducted in 2013 and 2018 ~~by the Center for Health Statistics and Information of the National Health Commission (NHC) of China (formerly the Ministry of Health)~~. Each survey employed the same three-stage, stratified, cluster random sampling procedure. At the first stage, urban and rural location and socio-economic regions were used to classify cities and counties into six groups: eastern urban, eastern rural, central urban, central rural, western urban and western rural. Simple random sampling was used to select cities and counties from each group. The random sample process was repeated for three times to select the ones most close to the parameters (e.g. fertility rate, mortality rate and demographic structure etc.) representing the general. Then five sub-districts or townships were randomly selected from each city or county based on the rank of number of population. Finally, three communities or villages from each sub-district or township were randomly selected and all households in the selected sub-district or township were included in the survey. In total, 93,613 households were included in the survey of 2013 and 94,074 in the survey of 2018.

Data collection

The trained primary health workers administered face-to-face survey to each family member in the sampled households using structured questionnaire. The questionnaires used in the

two surveys had a same structure and involved similar questions, which included the general demographic and socio-economic characteristics of the sampled households and family members, the utilization of and expenditures on health services. There is one section on the childbirth that asked questions about the use of antennal-antenatal care, place of delivery, mode of delivery and caesarean delivery for maternal request. We included women who had the last live birth within the five years before the survey in this study to avoid overrepresentation of women who have one more child.

Data analysis Measures

The outcome measure was the percentage of births by CS. In the survey, the mode of delivery was asked with the following question: "How did the birth take place: a) vaginal delivery; b) caesarean section". If the answer was "caesarean section", the following question was "Who was the most important person of proposing CS: a) myself; b) husband; c) parent; d) doctor; e) others". We considered CS as a woman request in the analysis if the woman choose the option "a (myself)".

We examined demographic and socio-economic factors associated with the use of CS that included: maternal age (<25, 25-34, ≥35); maternal educational level (illiterate or primary school, secondary school, high school/professional school or higher); location of resident (urban, rural); living in different socio-economic region (developed Eastern, less developed Central, least developed Western); health insurance coverage; income quartile; parity, defined as the number of live births born by a woman; and place of delivery, defined as type of health facility where the live birth occurred (county or higher level hospital, maternal and child health hospital, township/community health center, private hospital). There are three basic health insurance schemes in China: Urban Employee Basic Health Insurance (UEBMI), Urban Residents Basic Health Insurance (URBMI) and rural New Cooperative Medical Scheme (NCMS). In recent years, URBMI was integrated with NCMS in some provinces renamed as Urban and Rural Residents Basic Medical Insurance (URRBMI). Overall, UEBMI provides better coverage for both inpatient and outpatient care compared to URRBMI. In the analysis, we grouped URBMI, NCMS and URRBMI into one category as "URRBMI"; Health insurance coverage was grouped into: none coverage, UEBMI, URRBMI and and-others health insurances (including free medical service scheme for special sectors or labor insurance). Annual household income in the calendar year that preceded the survey included savings and household expenditure on consumables during that year. We generated income quartile by dividing household income by the number of individuals in the household, which reflected lowest income group (quartile 1), low income group (quartile 2), middle income group (quartile 3) and high income group (quartile 4).

Data analysis

We investigated changes of CS rate in 2008-2018 by location of residents urban and rural areas and across different socio-economic regions. We also examined CS rate among nulliparous and multiparous women by location and region in the study periods. We studied change of women request for CS by parity that the time period 2008-2018 was divided into 2008-2009, 2010-2012, 2013-2015 and 2016-2018. Chi-square test was used to test the difference by the study period. We conducted bi-variate and multi-variate logistic regression analysis to study explanatory variables associated with the use of CS for all and in stratification of urban and rural areas and by socio-economic regions in 2008-2018. In addition, we also stratified data in 2016-2018 to investigate study demographic and socio-economic factors associated with the use of CS in 2016-2018 after universal two-child policy in China for all and by nulliparous and multiparous women, by location and regions.

Ethical statement, patient and public involvement

This study is based on a secondary data analysis. The research team obtained the approval of the Center for Health Statistics and Information of the National Health Commission (NHC) of China (formerly the Ministry of Health) to access to de-identified birth dataset. -No patient involved. Approval from an ethics committee was not required.

Results:

Total 23,053 women who had a live birth in the study period 2008-2018 were included in the analysis (Table 1). The distribution of maternal age was relatively similar by the study periods, and more than 60% of women were aged at 25-34 years. The proportion of women who received high school and professional school or higher and those who had two or more children increased over time. Few women had no health insurance coverage, and a vast majority of women had enrolled in URRBMI. In addition, there were more women in urban areas giving birth than women in rural areas observed in the period of 2016-2018. The distribution of women living region was relatively similar over time. The majority of women gave birth in general hospital (county or higher level hospital) and this proportion increased over time. The proportion of women giving birth in community and township health centers decreased in both urban and rural areas across different socio-economic regions (Supplementary files: Table 1). In the 2018 survey, fewer women reported choosing to give birth in a private hospital.

CS rate

Nationwide, the overall CS rate increased from 40.9% in 2008 to 47.2% in 2014. After the scale-up of the two-child policy, the CS rate slightly decreased; it was 45.2% in 2018.

1) CS rate by urban and rural areas and across regions

In urban areas, the CS rate slightly increased from 50.4% in 2008 to 52.3% in 2014, and then slightly decreased to 47.8% in 2018. However, in rural areas the CS rate had significantly increased from 33.1% in 2008 to 43.8% in 2015. In rural areas there was also a slight decrease after the relaxation of the one-child policy. The CS rate in rural areas was 41.2% in 2018 (Figure 1a). A similar trend was found across different socio-economic regions (Figure 1b). We observed a significant increase in CS rate from 28.1% in 2008 to 38.6% in 2018 in the least developed western region. In the stratification of urban and rural areas by regions, in 2008 the CS rates in urban areas in the eastern, central and western regions were 50.9%, 62.3% and 37.4% respectively. The difference of CS rate in urban areas by region became very small in 2018 (48.1% in eastern, 49.2% in central and 46.6% in western region). The CS rates in rural areas across all regions increased between 2008 and 2018. The CS rates in the eastern and central rural areas were higher or close to the rate in urban areas in these two regions (Supplementary file: Figure 1).

2) CS rate by parity

Around half of nulliparous women in urban areas gave birth by CS between 2008 and 2014, and the proportion in rural areas grew significantly from 33.3% in 2008 to 49.6% in 2015. The CS rate among nulliparous women decreased rapidly in both urban (42.8% in 2018) and rural areas (37.5% in 2018) after the universal two-child policy (Figure 2a). The CS rate among multiparous women continued to increase from 35.3% in 2008 to 48.4% in 2018 with similar trends in both urban and rural areas (Figure 2b). We found similar finding in terms of the change of CS rate by parity across different socio-economic regions (Supplementary file: Figure 2).

Maternal request for CS

We examined maternal request for CS by the study periods (Table 2). According to women's self-report, the proportion of maternal request for CS among nulliparous women decreased from 35.8% in 2008-2009 to 24.4% in 2016-2018 ($P < 0.01$). In the stratification of residents location, maternal request for CS significantly decreased in urban areas from 36.8% in 2008-2009 to 22.2% in 2016-2018 ($p < 0.01$), however the change in rural areas was not statistically significant (from 33.5% in 2008-2009 to 29.4% in 2016-2018) (Supplementary files: Table 2). Among multiparous women, around one third of women reported maternal request for CS, and there was no significant change between 2008-2009 and 2016-2018.

1
2
3 In addition, the proportion of CS suggested by a doctor among nulliparous women increased
4 from 63.3% in 2008-2009 to 72.7% in 2016-2018 ($P < 0.01$), and there was no significant
5 change of doctors' suggestion for CS among multiparous women by the study period. For
6 both nulliparous and multiparous women, there were few CSs proposed by women's
7 husband and others (Table 2).

9
10

11 *Demographic and socio-economic Factors associated with the use of CS*

12 1) In the study period of 2008-2018

13
14
15
16
17 Table 3 shows factors associated with the use of CS in China by urban and rural areas over
18 the study period of 2008-2018. After adjusting for all explanatory variables, the use of CS
19 was less common in urban areas in the survey of 2018 (OR 0.85, 95%CI 0.78-0.92)
20 compared to the survey of 2013, however, it was more common in rural areas (OR 1.30,
21 95%CI 1.19-1.41) in the survey of 2018. Advanced maternal age (≥ 35), having secondary
22 education or higher and giving birth at high level hospital or private hospital were significantly
23 associated with the use of CS in both urban and rural areas. In rural areas, women from the
24 highest income quartile were more likely to have CS (OR 1.69, 95%CI 1.47-1.95) compared
25 to women from the lowest quartile, and multiparous women were less likely to have CS (OR
26 0.80, 95%CI 0.73-0.88) than nulliparous women. While these differences were not
27 statistically significant in urban areas.
28
29
30
31
32
33

34
35 Across different socio-economic regions, the use of CS increased in western region in the
36 survey of 2018 (OR 1.10, 95% CI 1.00-1.22) than the survey of 2013, while this difference
37 was not statistically significant in eastern and central regions (Supplementary files: Table 3).
38 Advanced maternal age (≥ 35) and giving birth at high level hospital or private hospital were
39 associated with the use of CS in all regions. In central and western regions, women who
40 lived in rural areas, were from low income quartile household and had more than one child
41 were less likely to have CS.
42
43
44
45
46

47 2) In the study period of 2016-2018

48
49 Following the universal two-child policy in China (2016-2018), women in urban areas who
50 were at advanced age (≥ 35), multiparous and gave birth at county or high level hospital or
51 private hospital were more likely to have CS (Supplementary files: Table 4). In rural areas, in
52 addition to maternal age and place of delivery, maternal education attainment and household
53 income were also positively associated with the use of CS. Factors associated with the use
54 of CS in eastern and central regions at the same study period were found similar in urban
55
56
57
58
59
60

1
2
3 areas and those in western region were found similar in rural areas (Supplementary files:
4 Table 5).
5

6
7 We examined the factors associated with the use of CS by parity in the era of two-child
8 policy. We found that advanced maternal age (≥ 35) and births occurred at private hospital
9 were significantly associated with the use of CS among nulliparous women after adjusting for
10 all explanatory variables, while the association between the use of CS and other socio-
11 economic factors was not statistically significant (Table 4). For multiparous women, women
12 who were older, had higher education attainment, had health insurance coverage, were from
13 wealthy household, lived in urban areas or eastern region and gave birth at higher level
14 hospital or private hospital were more likely to have CS after adjusting for all explanatory
15 variables (Table 4).

22 **Discussion**

23 *Summary of key findings*

24
25
26 In China, the CS rate increased between 2008 and 2015, which was, to a great extent,
27 attributable to a rapid increase of the use of CS in rural areas and the least developed
28 western region. After the scale-up of two-child policy, the CS rate slightly decreased in both
29 urban and rural areas and across socio-economic regions, particularly among nulliparous
30 women. The proportion of maternal request for CS decreased among nulliparous women in
31 urban areas over time, however, this proportion decreased slightly in rural areas that 30% of
32 women underwent CS due to maternal request for CS in 2016-2018. In the era of two-child
33 policy, advanced maternal age and births occurred in a private hospital were associated with
34 the use of CS among nulliparous women. The CS rate among multiparous women continued
35 to increase over time, and demographic and socio-economic factors were positively
36 associated with the use of CS among multiparous women.

44 *Strengths and limitations*

45
46 This study contributes to what is known about rates of CS in China, where most existing
47 studies are limited to a few hospitals or regions. It is a strength of this paper that with the
48 increase of population size and urbanization in China over the past two decades, the
49 National Household Health Services Survey adapted its sampling method in 2013 and
50 increased the sample size to achieve reliable representativeness of the general population
51 by urban and rural areas and across different socio-economic regions. It provides unique
52 insights into both mode of birth and whom households report proposed actual caesarean
53 births. However, several limitations in terms of data and analysis remain. First, all
54 information was based on women's reports, and the reasons for maternal request or doctor
55
56
57
58
59
60

suggestion for CS were not asked. We were not able to distinguish in this study how many CSs performed were medically indicated. Second, women's history of pregnancy (e.g. previous CS or others) was not available. We could not make a sub-group analysis on the use of CS among women with or without uterine scar. Third, we could not separate the effects of strategies to reduce unnecessary CS and the shift of the population policy on the use of CS in China. That said, we did observe a slight decrease of CS rate in line with the period of the universal two-child policy and the CS rate in urban areas and regions with a high baseline rate had a moderate change over time (2008-2018). Thus the interpretation of a decrease in CS rate following relaxation of the one-child policy should be made with caution.

Interpretations

We observed a rapid decrease of CS rate among nulliparous women in both urban and rural areas and across all regions in line with the period of universal two-child policy, which is consistent with the findings in other studies.^{98,154} However, any causal association remains speculative, not least because of the nuances within the one-child policy itself. In 1979, China announced its family planning policy to strictly control population size. The policy included rules of governing marriage, contraception, number of births and spacing where a second child was permitted.¹⁵⁶ The one child rule was strictest for urban residents and employees of the government agencies. In rural areas, a second child was generally allowed after five years, especially if the first born was a girl. Some ethnic minorities were permitted a third child. With socio-economic development and change of demographic structure, the Chinese government gradually relaxed the one-child policy over a decade with the entire population encouraged to have a second child since 2016.¹⁶⁷

The CS rate ~~increased~~ ~~decreased~~ moderately in urban areas and the eastern and central regions, which had a relatively high baseline CS rate. One plausible explanation is that this may be attributable to the introduction of policies and strategies aiming to reverse the high CS rate through a national top-down approach in China. Although, results of introducing comprehensive interventions to mitigate unnecessary CSs are mixed in previous studies.^{87,98,17,18}

We found that the CS rate increased dramatically in rural areas by all socio-economic regions between 2008-2015. This rise may be associated with a significant increase in the number of births occurring at secondary or higher-level (tertiary) hospitals, reflecting an increase in availability and accessibility of these services in these areas. The Chinese government had made strong commitment to reduce maternal and child mortality to achieve Millennium Development Goal (MDG) targets by 2015.¹⁹ The main strategy was to promote

1
2
3 hospital delivery, particularly in rural and poor areas with largely financial support from the
4 central government and partly from the provincial government.¹⁹ In the context of deepening
5 China's health system reform, the national plan of further strengthening the hospital delivery
6 for rural women in 2009 highlighted to provide the financial compensation for hospital
7 delivery through rural health insurance (NCMS), the earmarked government fund and
8 medical assistance program for the poor women in order to reduce financial burden placed
9 on the households.²⁰ By 2014, hospital delivery in rural areas was almost universal. Across
10 countries, the shift from community to hospital births is known to result in an increase in CS
11 rates for medically indicated and non-medical reasons.²¹ In China, cross-sectional research
12 has shown that while tertiary hospitals have the highest rates of CS for ambiguous
13 indications (i.e. Non-reassuring foetal heart tracing; failure to progress), secondary level
14 hospitals report greater use of CS for maternal request.²²

23 *Implications for practice*

24
25 Previous studies report maternal request for CS as a contributor to a rapid increase of CS
26 rate in China,²²⁻²⁵ despite the validity of the concept being widely debated internationally. For
27 women who reportedly prefer CS, the most common reasons for their preference are fear of
28 labor pain, safer for their baby and for themselves.¹¹⁰ In this context, family members (e.g.
29 husband or parent) also supported this choice to avoid an adverse event, especially in the
30 context of one child in a family policy. Moreover, in our study around one third of nulliparous
31 women reported self-request for CS in the era of one-child policy. This proportion
32 significantly decreased in urban areas over time, which may be associated with the shift from
33 strict one child in a family in urban areas to universal two children, and promotion of vaginal
34 births in hospital settings. This change did not occur in rural areas, which indicate the needs
35 of strengthening quality of maternity care including services delivery and women's
36 experience in rural areas.

37
38 Efforts to promote vaginal birth in China included midwifery care training (e.g. training more
39 professional midwives, establishment of standardized evaluation scheme of midwifery
40 practice etc.), pain relief for vaginal birth and informing women about benefits and risks of
41 different mode of delivery.²⁶ Other studies, largely in big cities and tertiary hospitals report
42 woman-centered pregnancy and childbirth care which includes provision of antenatal classes
43 to shape women's beliefs and confidence to childbirth, build connection and trust between
44 doctors, midwives and women as well as provide continuous supports during labor and
45 birth.^{154, 23, 27} At the same time, pharmacological and non-pharmacological options for labor
46 pain management have become available. However, the midwifery workforce in China is
47 insufficient. Quality of midwifery care can vary by hospitals, and urban-rural disparity in
48

60

1
2
3 midwife numbers and training is anecdotally reported. Lack of support during labor, lack of
4 pain relief and sub-optimal birth environment were reported as the main reasons that rural
5 women requested for CS.²⁸ Hence, strengthening midwifery care to improve women's
6 experience on childbirth, particularly in rural areas will be critical to optimize the use of CS in
7
8
9
10 China.

11 *Implications for further research*

12
13
14 In the era of two-child policy, only advanced maternal age and giving birth in a private
15 hospital were positively associated with the use of CS by nulliparous women. Since 2013
16 onward, the latest health-care delivery reform in China encouraged competition between
17 public and private hospitals, and set out the target of private hospitals sharing 20% of market
18 by 2015. The burgeoning of private hospital provision in China is driven by market forces,
19 with providers charges unregulated unless contracted by the basic health insurance
20 schemes.²⁹ Studies in other countries report much higher CSs rate in private hospitals due to
21 profit driven behavior.³⁰⁻³² It needs further study to have a better understanding on the use of
22 CS in private hospitals in China in order to propose evidence-based recommendations for
23 relevant policy development. In addition, we found that CS rate among multiparous women
24 continued to increase over time, especially in urban areas, which may be associated with the
25 increase of women who underwent repeat CS. Based on the NMNMSS data, Liang and
26 colleagues reported a high CS rate among multiparous women with a uterine scar and it was
27 unchanged over time.⁹⁸ In China, repeat CS is often suggested and accepted for women
28 with a previous CS to mitigate the risk of uterine rupture or other adverse event, despite
29 repeat CS share similar risks. We can only speculate that there may be increasing referrals
30 of women with a previous CS to high level or specialty hospitals. The accessibility, functional
31 referral and affordability of such services as well as health outcomes, particularly for socio-
32 economic vulnerable women should be rigorous assessed in further research.

33 **Conclusion**

34
35
36 A rapid increase of CS rate in rural areas and less developed western region contributed to
37 the increase of CS rate in China over the past decade. The population policy shift, alongside
38 facility policies to limit the use of unnecessary CS, are likely factors contributing to the
39 reduction of CS in urban areas. Strategies at system, organization and individual levels to
40 mitigate unnecessary CSs should be continually strengthened, especially in rural areas and
41 western region. Improving midwifery care will be fundamental to ensure safety and positive
42 childbirth experience in the era of two-child in a family in China.

Research Ethics Approval Statement

We obtained the permission to access to de-identified birth dataset ~~and conduct secondary data analysis~~ No patient was involved, and thus an approval from an ethics committee was not required.

Contributors

QL conceived and led the overall analysis and wrote the first manuscript draft. YGZ conducted the data analysis and commented on the manuscript. XJT and JZ contributed to the analysis and commented on the manuscript. CK contributed to the study concept and overall analysis and participated in the manuscript writing.

Funding statement

This work was supported by the Kunshan Municipal Government research funding.

Conflicts of Interest

The authors declared no conflicts of interest.

3 **Figure 2 Proportion of women giving birth by caesarean section by parity by urban and**
4 **rural areas, 2008-2018**
5

6 Caesarean section rate among nulliparous women decreased around 2016 in both urban and rural areas,
7 while there was a large increase in the number of multiparous women delivering by caesarean section.

60STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5-6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6
Bias	9	Describe any efforts to address potential sources of bias	5
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	6
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	6
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	7
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	17 (Table 1)
Outcome data	15*	Report numbers of outcome events or summary measures	7-8

1			
2	Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-
3			adjusted estimates and their precision (eg, 95% confidence
4			interval). Make clear which confounders were adjusted for and why
5			they were included
6			
7			(b) Report category boundaries when continuous variables were
8			categorized
9			
10			(c) If relevant, consider translating estimates of relative risk into
11			absolute risk for a meaningful time period
12	Other analyses	17	Report other analyses done—eg analyses of subgroups and
13			interactions, and sensitivity analyses
14			
15	Discussion		
16	Key results	18	Summarise key results with reference to study objectives
17			
18	Limitations	19	Discuss limitations of the study, taking into account sources of
19			potential bias or imprecision. Discuss both direction and magnitude
20			of any potential bias
21	Interpretation	20	Give a cautious overall interpretation of results considering
22			objectives, limitations, multiplicity of analyses, results from similar
23			studies, and other relevant evidence
24			
25	Generalisability	21	Discuss the generalisability (external validity) of the study results
26			
27	Other information		
28	Funding	22	Give the source of funding and the role of the funders for the
29			present study and, if applicable, for the original study on which the
30			present article is based
31			

32

33 *Give information separately for exposed and unexposed groups.

Abstract

Objectives: Since 2009, China has introduced policies, principally targeting health professionals, to reduce caesarean section (CS) overuse. In 2016, China endorsed a universal two-child policy. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS. This study investigated changes to CS rates in 2008-2018, and factors associated with CS use during the period of transition from the one-to-two child policy era.

Design: We used births data from cross-sectional National Household Health Services Surveys in 2013 and 2018.

Setting: Population-based national survey

Participants: Women who had the last live birth within the five years before the survey

Primary outcome measure: Caesarean section rate

Results: Overall CS use increased from 40.9% in 2008 to 47.2% in 2014 with significant increase in rural areas and the western region, and slightly decreased to 45.2% in 2018 with the greatest decrease among nulliparous women. Maternal request for CS by urban nulliparous women decreased from 36.8% in 2008-2009 to 22.2% in 2016-2018, but this change was not statistically significant in rural areas. Maternal age over 35 years old (OR 2.40, 95%CI 1.76-3.31) and births occurred at private hospital (OR 1.52, 95%CI 1.25-1.86) were associated with CS use among nulliparous women in 2016-2018. The CS rate among multiparous women increased over time. Individual socio-economic factors associated with CS use among multiparous women.

Conclusions: The CS rate rise in China in 2008-2018 is attributable to increased use in rural areas and the less developed Western region. The population policy shift, alongside facility policies for unnecessary CS reduction, are likely factors in CS reduction in urban areas. The challenge remains to reduce unnecessary CS, at the same time as providing safe, universal access to CSs for women in need.

Strengths and limitations of this study

- This study used well-established population-based national survey data to examine the change of caesarean section rate in China by urban and rural areas, across regions and women's characteristics over the periods of population policy shift.
- This study could not separate the effects of strategies to reduce unnecessary CS and the shift of the population policy on the use of CS in China.
- We are not able to conduct more sub-groups analysis such as previous caesarean section or caesarean section with or without medical indications due to unavailable data.

Introduction

Globally, Caesarean Section (CS) rates are rising in all regions with one of fifth of live births being by CS in 2015.¹ Complex social, cultural, economic, and medical factors are known drivers of CS use.² Overuse and underuse of CS represent simultaneous challenges for many health systems. Overuse of CS, where CS is performed without or on the basis of ambiguous medical indications has been associated with increased risk of maternal and newborn adverse outcomes and increased costs for health systems and individuals.^{3, 4} Meanwhile, the low use of CS implies limited accessibility to this life-saving procedures for women in need during childbirth.¹ The World Health Organization (WHO) Statement on Caesarean Section Rates suggests that CS rates at population level higher than 10% are not associated with reductions in maternal and newborn mortality rates, while every effort should be made to provide CS to women in need.⁵

China has witnessed a rapid increase in the use of CS since 1990s.⁶⁻⁹ According to the data from the National Household Health Services Surveys in China, the CS rate increased from 19.2% in 2003 to 36.3% in 2011.⁷ Many CSs in China are not medically indicated.¹⁰ There is evidence that individual, health system and socio-cultural factors are driving the use of CS.¹¹ Women may request CS because of fear of labor pain, fear of risk and adverse outcomes of vaginal delivery, perceived convenience of CS for birth plan and control and perceived CS as a safe option for childbirth.¹¹ In China, facility-based delivery is a national strategy to reduce risks of adverse outcomes for mothers and newborns. Almost all births occurred in health facilities by 2015. It has been argued that financial incentive and fear of malpractice may shape the preference of health professionals for performing CS in the hospital settings.^{11, 12}

Since 2009, the Chinese government has increasingly introduced policies and strategies at national and local levels to restrict the use of unnecessary CS.⁹ These strategies largely targeted health professionals. They include revising clinical guideline to strict control of CS indications, strengthening training of midwifery care and audit of CS without medical indications, setting facility CS rate targets and removing financial incentives for CS. China has gradually relaxed family planning policy since 2013, with all families being allowed and encouraged to have a second child in 2016. Advanced maternal age and previous CS may indicate changes in obstetric risks, which raise the concerns on the need for and safety of CS.^{13, 14}

Recent studies that used data from the National Maternal Near Miss Surveillance System (NMNMSS) reported a moderate decrease of CS rate in some big cities, which coincided with the period of relaxation of the one-child policy between 2012-2016.^{8, 9} This decrease in

1
2
3 CS rate may be attributable to facility strategies to reduce the use of CS without medical
4 indications. However, the authors also acknowledged the limitation of NMNMS data in
5 over-representing urban populations. Little is known about trends of CS use in rural areas,
6 across regions at different stages of socio-economic development, nor how facility strategies
7 to mitigate unnecessary CS and the population policy shift have affected the use of CS in
8 these places.
9
10
11
12

13 This study used cross-sectional data from the National Household Health Services Survey
14 conducted in 2013 and 2018, which achieved reliable representativeness of the general
15 population by urban and rural areas and across socio-economic development regions. We
16 investigated changes to CS rates between 2008 and 2018, by urban and rural location, and
17 across socio-economic regions in China. It sought to examine maternal request for CS by
18 the study periods and by parity, as well as demographic and socio-economic factors
19 associated with use of CS during the period of transition from the one-to-two child policy era.
20
21
22
23
24

25 **Methods**

26 *Data source*

27 We obtained the permission to access to birth dataset from National Household Health
28 Services Surveys conducted in 2013 and 2018. Each survey employed the same three-
29 stage, stratified, cluster random sampling procedure. At the first stage, urban and rural
30 location and socio-economic regions were used to classify cities and counties into six
31 groups: eastern urban, eastern rural, central urban, central rural, western urban and western
32 rural. Simple random sampling was used to select cities and counties from each group. The
33 random sample process was repeated for three times to select the ones most close to the
34 parameters (e.g. fertility rate, mortality rate and demographic structure etc.) representing the
35 general. Then five sub-districts or townships were randomly selected from each city or
36 county based on the rank of number of population. Finally, three communities or villages
37 from each sub-district or township were randomly selected and all households in the
38 selected sub-district or township were included in the survey. In total, 93,613 households
39 were included in the survey of 2013 and 94,074 in the survey of 2018.
40
41
42
43
44
45
46
47
48
49

50 The trained primary health workers administered face-to-face survey to each family member
51 in the sampled households using structured questionnaire. The questionnaires used in the
52 two surveys had a same structure and involved similar questions, which included the general
53 demographic and socio-economic characteristics of the sampled households and family
54 members, the utilization of and expenditures on health services. There is one section on the
55 childbirth that asked questions about the use of antenatal care, place of delivery, mode of
56
57
58
59
60

1
2
3 delivery and caesarean delivery for maternal request. We included women who had the last
4 live birth within the five years before the survey in this study to avoid overrepresentation of
5 women who have one more child.
6
7

8 *Measures*

9
10 The outcome measure was CS rate, the percentage of births by CS. In the survey, the mode
11 of delivery was asked with the following question: "How did the birth take place: a) vaginal
12 delivery; b) caesarean section". If the answer was "caesarean section", the following
13 question was "Who was the most important person of proposing CS: a) myself; b) husband;
14 c) parent; d) doctor; e) others". We considered CS as a woman request in the analysis if the
15 woman choose the option "a (myself)".
16
17
18
19

20
21 We examined demographic and socio-economic factors associated with the use of CS that
22 included: maternal age (<25, 25-34, ≥35); maternal educational level (illiterate or primary
23 school, secondary school, high school/professional school or higher); location of resident
24 (urban, rural); living in different socio-economic region (developed Eastern, less developed
25 Central, least developed Western); health insurance coverage; income quartile; parity,
26 defined as the number of live births born by a woman; and place of delivery, defined as type
27 of health facility where the live birth occurred (county or higher level hospital, maternal and
28 child health hospital, township/community health center, private hospital). There are three
29 basic health insurance schemes in China: Urban Employee Basic Health Insurance
30 (UEBMI), Urban Residents Basic Health Insurance (URBMI) and rural New Cooperative
31 Medical Scheme (NCMS). In recent years, URBMI was integrated with NCMS in some
32 provinces renamed as Urban and Rural Residents Basic Medical Insurance (URRBMI).
33 Overall, UEBMI provides better coverage for both inpatient and outpatient care compared to
34 URRBMI. In the analysis, we grouped URBMI, NCMS and URRBMI into one category as
35 "URRBMI". Health insurance coverage was grouped into: none coverage, UEBMI, URRBMI
36 and others (including free medical service scheme for special sectors or labor insurance).
37 Annual household income in the calendar year that preceded the survey included savings
38 and household expenditure on consumables during that year. We generated income quartile
39 by dividing household income by the number of individuals in the household, which reflected
40 lowest income group (quartile 1), low income group (quartile 2), middle income group
41 (quartile 3) and high income group (quartile 4).

54 *Data analysis*

55
56
57 We investigated changes of CS rate in 2008-2018 by urban and rural areas and across
58 different socio-economic regions. We also examined CS rate among nulliparous and
59
60

1
2
3 multiparous women by location and region in the study periods. We studied change of
4 women request for CS by parity that the time period 2008-2018 was divided into 2008-2009,
5 2010-2012, 2013-2015 and 2016-2018. Chi-square test was used to test the difference by
6 the study period. We conducted bi-variate and multi-variate logistic regression analysis to
7 study explanatory variables associated with the use of CS for all and in stratification of urban
8 and rural areas and by socio-economic regions in 2008-2018. In addition, we stratified data
9 in 2016-2018 to study demographic and socio-economic factors associated with the use of
10 CS after universal two-child policy in China for all and by nulliparous and multiparous
11 women, by location and regions. We applied Stata 13.0 for data analysis.

26
27
28 No patient involved.
29

30 **Results:**

31
32 Total 23,053 women who had a live birth in the study period 2008-2018 were included in the
33 analysis (Table 1). The distribution of maternal age was relatively similar by the study
34 periods, and more than 60% of women were aged at 25-34 years. The proportion of women
35 who received high school and professional school or higher and those who had two or more
36 children increased over time. Few women had no health insurance coverage, and a vast
37 majority of women had enrolled in URRBMI. In addition, there were more women in urban
38 areas giving birth than women in rural areas observed in the period of 2016-2018. The
39 distribution of women living region was relatively similar over time. The majority of women
40 gave birth in general hospital (county or higher level hospital) and this proportion increased
41 over time. The proportion of women giving birth in community and township health centers
42 decreased in both urban and rural areas across different socio-economic regions
43 (Supplementary files: Table 1). In the 2018 survey, fewer women reported choosing to give
44 birth in a private hospital.
45
46
47
48
49
50
51
52

53 **CS rate**

54
55
56 Nationwide, the overall CS rate increased from 40.9% in 2008 to 47.2% in 2014. After the
57 scale-up of the two-child policy, the CS rate slightly decreased; it was 45.2% in 2018.
58
59
60

1) CS rate by urban and rural areas and across regions

In urban areas, the CS rate slightly increased from 50.4% in 2008 to 52.3% in 2014, and then slightly decreased to 47.8% in 2018. However, in rural areas the CS rate had significantly increased from 33.1% in 2008 to 43.8% in 2015. In rural areas there was also a slight decrease after the relaxation of the one-child policy. The CS rate in rural areas was 41.2% in 2018 (Figure 1a). A similar trend was found across different socio-economic regions (Figure 1b). We observed a significant increase in CS rate from 28.1% in 2008 to 38.6% in 2018 in the least developed western region. In the stratification of urban and rural areas by regions, in 2008 the CS rates in urban areas in the eastern, central and western regions were 50.9%, 62.3% and 37.4% respectively. The difference of CS rate in urban areas by region became very small in 2018 (48.1% in eastern, 49.2% in central and 46.6% in western region). The CS rates in rural areas across all regions increased between 2008 and 2018. The CS rates in the eastern and central rural areas were higher or close to the rate in urban areas in these two regions (Supplementary file: Figure 1).

2) CS rate by parity

Around half of nulliparous women in urban areas gave birth by CS between 2008 and 2014, and the proportion in rural areas grew significantly from 33.3% in 2008 to 49.6% in 2015. The CS rate among nulliparous women decreased rapidly in both urban (42.8% in 2018) and rural areas (37.5% in 2018) after the universal two-child policy (Figure 2a). The CS rate among multiparous women continued to increase from 35.3% in 2008 to 48.4% in 2018 with similar trends in both urban and rural areas (Figure 2b). We found similar finding in terms of the change of CS rate by parity across different socio-economic regions (Supplementary file: Figure 2).

Maternal request for CS

We examined maternal request for CS by the study periods (Table 2). According to women's self-report, the proportion of maternal request for CS among nulliparous women decreased from 35.8% in 2008-2009 to 24.4% in 2016-2018 ($P < 0.01$). In the stratification of residents location, maternal request for CS significantly decreased in urban areas from 36.8% in 2008-2009 to 22.2% in 2016-2018 ($p < 0.01$), however the change in rural areas was not statistically significant (from 33.5% in 2008-2009 to 29.4% in 2016-2018) (Supplementary files: Table 2). Among multiparous women, around one third of women reported maternal request for CS, and there was no significant change between 2008-2009 and 2016-2018.

In addition, the proportion of CS suggested by a doctor among nulliparous women increased from 63.3% in 2008-2009 to 72.7% in 2016-2018 ($P < 0.01$), and there was no significant

1
2
3 change of doctors' suggestion for CS among multiparous women by the study period. For
4 both nulliparous and multiparous women, there were few CSs proposed by women's
5 husband and others (Table 2).

13

14 Table 3 shows factors associated with the use of CS in China by urban and rural areas over
15 the study period of 2008-2018. After adjusting for all explanatory variables, the use of CS
16 was less common in urban areas in the survey of 2018 (OR 0.85, 95%CI 0.78-0.92)
17 compared to the survey of 2013, however, it was more common in rural areas (OR 1.30,
18 95%CI 1.19-1.41) in the survey of 2018. Advanced maternal age (≥ 35), having secondary
19 education or higher and giving birth at high level hospital or private hospital were significantly
20 associated with the use of CS in both urban and rural areas. In rural areas, women from the
21 highest income quartile were more likely to have CS (OR 1.69, 95%CI 1.47-1.95) compared
22 to women from the lowest quartile, and multiparous women were less likely to have CS (OR
23 0.80, 95%CI 0.73-0.88) than nulliparous women. While these differences were not
24 statistically significant in urban areas.
25
26
27
28
29
30

31 Across different socio-economic regions, the use of CS increased in western region in the
32 survey of 2018 (OR 1.10, 95% CI 1.00-1.22) than the survey of 2013, while this difference
33 was not statistically significant in eastern and central regions (Supplementary files: Table 3).
34 Advanced maternal age (≥ 35) and giving birth at high level hospital or private hospital were
35 associated with the use of CS in all regions. In central and western regions, women who
36 lived in rural areas, were from low income quartile household and had more than one child
37 were less likely to have CS.
38
39
40
41
42

43 2) In the study period of 2016-2018

44
45

46 Following the universal two-child policy in China (2016-2018), women in urban areas who
47 were at advanced age (≥ 35), multiparous and gave birth at county or high level hospital or
48 private hospital were more likely to have CS (Supplementary files: Table 4). In rural areas, in
49 addition to maternal age and place of delivery, maternal education attainment and household
50 income were also positively associated with the use of CS. Factors associated with the use
51 of CS in eastern and central regions at the same study period were found similar in urban
52 areas and those in western region were found similar in rural areas (Supplementary files:
53 Table 5).

1
2
3 We examined the factors associated with the use of CS by parity in the era of two-child
4 policy. We found that advanced maternal age (≥ 35) and births occurred at private hospital
5 were significantly associated with the use of CS among nulliparous women after adjusting for
6 all explanatory variables, while the association between the use of CS and other socio-
7 economic factors was not statistically significant (Table 4). For multiparous women, women
8 who were older, had higher education attainment, had health insurance coverage, were from
9 wealthy household, lived in urban areas or eastern region and gave birth at higher level
10 hospital or private hospital were more likely to have CS after adjusting for all explanatory
11 variables (Table 4).

17 **Discussion**

18 *Summary of key findings*

19
20
21
22 In China, the CS rate increased between 2008 and 2015, which was, to a great extent,
23 attributable to a rapid increase of the use of CS in rural areas and the least developed
24 western region. After the scale-up of two-child policy, the CS rate slightly decreased in both
25 urban and rural areas and across socio-economic regions, particularly among nulliparous
26 women. The proportion of maternal request for CS decreased among nulliparous women in
27 urban areas over time, however, this proportion decreased slightly in rural areas that 30% of
28 women underwent CS due to maternal request for CS in 2016-2018. In the era of two-child
29 policy, advanced maternal age and births occurred in a private hospital were associated with
30 the use of CS among nulliparous women. The CS rate among multiparous women continued
31 to increase over time, and demographic and socio-economic factors were positively
32 associated with the use of CS among multiparous women.

40 *Strengths and limitations*

41
42
43 This study contributes to what is known about rates of CS in China, where most existing
44 studies are limited to a few hospitals or regions. It is a strength of this paper that with the
45 increase of population size and urbanization in China over the past two decades, the
46 National Household Health Services Survey adapted its sampling method in 2013 and
47 increased the sample size to achieve reliable representativeness of the general population
48 by urban and rural areas and across different socio-economic regions. It provides unique
49 insights into both mode of birth and whom households report proposed actual caesarean
50 births. However, several limitations in terms of data and analysis remain. First, all
51 information was based on women's reports, and the reasons for maternal request or doctor
52 suggestion for CS were not asked. We were not able to distinguish in this study how many
53 CSs performed were medically indicated. Second, women's history of pregnancy (e.g.
54
55
56
57
58
59
60

1
2
3 previous CS or others) was not available. We could not make a sub-group analysis on the
4 use of CS among women with or without uterine scar. Third, we could not separate the
5 effects of strategies to reduce unnecessary CS and the shift of the population policy on the
6 use of CS in China. That said, we did observe a slight decrease of CS rate in line with the
7 period of the universal two-child policy and the CS rate in urban areas and regions with a
8 high baseline rate had a moderate change over time (2008-2018). Thus the interpretation of
9 a decrease in CS rate following relaxation of the one-child policy should be made with
10 caution.
11
12
13
14
15

16 *Interpretations*

17
18 We observed a rapid decrease of CS rate among nulliparous women in both urban and rural
19 areas and across all regions in line with the period of universal two-child policy, which is
20 consistent with the findings in other studies.^{9,15} However, any causal association remains
21 speculative, not least because of the nuances within the one-child policy itself. In 1979,
22 China announced its family planning policy to strictly control population size. The policy
23 included rules of governing marriage, contraception, number of births and spacing where a
24 second child was permitted.¹⁶ The one child rule was strictest for urban residents and
25 employees of the government agencies. In rural areas, a second child was generally allowed
26 after five years, especially if the first born was a girl. Some ethnic minorities were permitted a
27 third child. With socio-economic development and change of demographic structure, the
28 Chinese government gradually relaxed the one-child policy over a decade with the entire
29 population encouraged to have a second child since 2016.¹⁷
30
31
32
33
34
35
36
37

38 The CS rate decreased moderately in urban areas and the eastern and central regions,
39 which had a relatively high baseline CS rate. One plausible explanation is that this may be
40 attributable to the introduction of policies and strategies aiming to reverse the high CS rate
41 through a national top-down approach in China. Although, results of introducing
42 comprehensive interventions to mitigate unnecessary CSs are mixed in previous studies.^{8,9,18}
43
44
45
46

47 We found that the CS rate increased dramatically in rural areas by all socio-economic
48 regions between 2008-2015. This rise may be associated with a significant increase in the
49 number of births occurring at secondary or higher-level (tertiary) hospitals, reflecting an
50 increase in availability and accessibility of these services in these areas. The Chinese
51 government had made strong commitment to reduce maternal and child mortality to achieve
52 Millennium Development Goal (MDG) targets by 2015.¹⁹ The main strategy was to promote
53 hospital delivery, particularly in rural and poor areas with largely financial support from the
54 central government and partly from the provincial government.¹⁹ In the context of deepening
55 China's health system reform, the national plan of further strengthening the hospital delivery
56
57
58
59

1
2
3 for rural women in 2009 highlighted to provide the financial compensation for hospital
4 delivery through rural health insurance (NCMS), the earmarked government fund and
5 medical assistance program for the poor women in order to reduce financial burden placed
6 on the households.²⁰ By 2014, hospital delivery in rural areas was almost universal. Across
7 countries, the shift from community to hospital births is known to result in an increase in CS
8 rates for medically indicated and non-medical reasons.²¹ In China, cross-sectional research
9 has shown that while tertiary hospitals have the highest rates of CS for ambiguous
10 indications (i.e. Non-reassuring foetal heart tracing; failure to progress), secondary level
11 hospitals report greater use of CS for maternal request.²²

12 13 14 15 16 17 18 *Implications for practice*

19
20 Previous studies report maternal request for CS as a contributor to a rapid increase of CS
21 rate in China,²²⁻²⁵ despite the validity of the concept being widely debated internationally. For
22 women who reportedly prefer CS, the most common reasons for their preference are fear of
23 labor pain, safer for their baby and for themselves.¹¹ In this context, family members (e.g.
24 husband or parent) also supported this choice to avoid an adverse event, especially in the
25 context of one child in a family policy. Moreover, in our study around one third of nulliparous
26 women reported self-request for CS in the era of one-child policy. This proportion
27 significantly decreased in urban areas over time, which may be associated with the shift from
28 strict one child in a family in urban areas to universal two children, and promotion of vaginal
29 births in hospital settings. This change did not occur in rural areas, which indicate the needs
30 of strengthening quality of maternity care including services delivery and women's
31 experience in rural areas.

32
33 Efforts to promote vaginal birth in China included midwifery care training (e.g. training more
34 professional midwives, establishment of standardized evaluation scheme of midwifery
35 practice etc.), pain relief for vaginal birth and informing women about benefits and risks of
36 different mode of delivery.²⁶ Other studies, largely in big cities and tertiary hospitals report
37 woman-centered pregnancy and childbirth care which includes provision of antenatal classes
38 to shape women's beliefs and confidence to childbirth, build connection and trust between
39 doctors, midwives and women as well as provide continuous supports during labor and
40 birth.^{15, 23, 27} At the same time, pharmacological and non-pharmacological options for labor
41 pain management have become available. However, the midwifery workforce in China is
42 insufficient. Quality of midwifery care can vary by hospitals, and urban-rural disparity in
43 midwife numbers and training is anecdotally reported. Lack of support during labor, lack of
44 pain relief and sub-optimal birth environment were reported as the main reasons that rural
45 women requested for CS.²⁸ Hence, strengthening midwifery care to improve women's

2
3 experience on childbirth, particularly in rural areas will be critical to optimize the use of CS in
4 China.
5

6 7 *Implications for further research*

8
9 In the era of two-child policy, only advanced maternal age and giving birth in a private
10 hospital were positively associated with the use of CS by nulliparous women. Since 2013
11 onward, the latest health-care delivery reform in China encouraged competition between
12 public and private hospitals, and set out the target of private hospitals sharing 20% of market
13 by 2015. The burgeoning of private hospital provision in China is driven by market forces,
14 with providers charges unregulated unless contracted by the basic health insurance
15 schemes.²⁹ Studies in other countries report much higher CSs rate in private hospitals due to
16 profit driven behavior.³⁰⁻³² It needs further study to have a better understanding on the use of
17 CS in private hospitals in China in order to propose evidence-based recommendations for
18 relevant policy development. In addition, we found that CS rate among multiparous women
19 continued to increase over time, especially in urban areas, which may be associated with the
20 increase of women who underwent repeat CS. Based on the NMNMSS data, Liang and
21 colleagues reported a high CS rate among multiparous women with a uterine scar and it was
22 unchanged over time.⁹ In China, repeat CS is often suggested and accepted for women with
23 a previous CS to mitigate the risk of uterine rupture or other adverse event, despite repeat
24 CS share similar risks. We can only speculate that there may be increasing referrals of
25 women with a previous CS to high level or specialty hospitals. The accessibility, functional
26 referral and affordability of such services as well as health outcomes, particularly for socio-
27 economic vulnerable women should be rigorous assessed in further research.

38
39

40 **Conclusion**

41
42 A rapid increase of CS rate in rural areas and less developed western region contributed to
43 the increase of CS rate in China over the past decade. The population policy shift, alongside
44 facility policies to limit the use of unnecessary CS, are likely factors contributing to the
45 reduction of CS in urban areas. Strategies at system, organization and individual levels to
46 mitigate unnecessary CSs should be continually strengthened, especially in rural areas and
47 western region. Improving midwifery care will be fundamental to ensure safety and positive
48 childbirth experience in the era of two-child in a family in China.

5

6 Caesarean section rate in urban areas slightly decreased between 2008 and 2018, while it had increased
7 in rural areas. Across regions, a large increase occurred in less developed Western region.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5-6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	5
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6
Bias	9	Describe any efforts to address potential sources of bias	5
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	6
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	6
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	7
		(b) Give reasons for non-participation at each stage	NA
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	7
		(b) Indicate number of participants with missing data for each variable of interest	17 (Table 1)
Outcome data	15*	Report numbers of outcome events or summary measures	7-8

Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	8-9
		(b) Report category boundaries when continuous variables were categorized	NA
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	8-9
Discussion			
Key results	18	Summarise key results with reference to study objectives	9
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	9-10
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	10-12
Generalisability	21	Discuss the generalisability (external validity) of the study results	13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	NA

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.

The authors confirmed that the manuscript writing followed the STORBE checklist for cross-sectional studies.
