# ABSTRACT

# Objective

Precarious employment is characterized by instability, lack of protection, and economic vulnerability. The objective of this study was to assess the association between temporary contracts (TC) and mortality.

## Design

Cohort study

## Setting

Rome, Italy

# Participants

All employees, aged 25-65 years, from the Rome Longitudinal Study followed from 21 Oct 2001 to the first date among death, migration from Rome, or 31 Dec 2015.

## Primary and secondary outcome measures

We investigated all-cause, cardiovascular, and accidental mortality. We considered gender, age, place of birth, education, temporary vs. permanent contract, and sector of employment. We used Cox models to investigate the association between type of contract and total, cardiovascular and accidental mortality in men and women, overall and by sector of employment.

# Results

We analyzed 597,834 subjects. The proportion of TC varied by gender (9.6% in men and 13.3% in women) and by sector of employment, ranging from 4.5% (public administration) to 27% (recreational, cultural, sports activities) in men. During the study period 21,136 subjects died. Men with TC, compared to those with permanent contracts, had greater overall mortality risk (HR=1.16, 95%CI: 1.09-1.24), cardiovascular mortality (HR=1.29, 95%CI: 1.14-1.45), and accidental mortality (HR=1.27, 95%CI: 1.04-1.57). In men, the association varied widely among different economic sectors, with greater risks in the industry, building constructions, and social services sectors. In women, the association between TC and mortality was found in the sector of sales and transports only.

#### Conclusions

TC should be taken into account as a determinant of health in particular for specific economic sectors.

Keywords: temporary employment, longitudinal study, mortality, vulnerability.

# Strengths and limitations of this study

- The study was based on 597,834 employees aged between 25 and 65 years residents in a metropolitan area, followed for 14 years.
- Census information, linked to health data, allowed a detailed analysis of health outcomes related to temporary work.
- The information on sector of employment allowed to investigate health outcomes related to temporary work in specific sectors.
- The lack of information about job histories was a strong limit of our study.
- There was a lack of information on employees' health and behavioral risk factors.

 **BMJ** Open

#### INTRODUCTION

During the last decades, increased flexibility in the labor market led to the spread of various forms of non-standard and precarious employment in Europe.[1] Due to the growth of evidence on the potential implications on health status, precariousness has been suggested as an emerging social determinant of health.[2] Some studies showed a social gradient in precarious contracts, in terms of educational level and job type.[3,4] In addition, a higher proportion of precarious contracts was reported among women,[5] young adults,[1] and migrants.[6]

Despite the growing body of research, some concerns remain about the definition of precarious employment. According to the seminal work of Rodgers and Rodgers,[7] precariousness is a complex construct that encompasses different dimensions involving employment instability and insecurity, lack of protection, and economic vulnerability. Although some multidimensional methods have been developed to assess precariousness,[8,9] in public health research it is frequent to focus on a specific domain using a one-dimensional approach. Within these domains, temporary employment, an objective measure of precariousness, is one of the most investigated.[10]

Few studies analyzed the effect of type of contract on mortality, showing an association between temporary contracts and mortality in specific subgroups of workers.[11-14] However, all mortality studies were conducted in Nordic European countries and none investigated the impact of temporary contracts among different economic sectors. As rate of temporary contracts may vary widely among economic sectors, the latter were evaluated as confounding factors.[13] Due to the worse working conditions of temporary employees, it is reasonable to hypothesize a joint effect between sector-related and contract-related health risks. Therefore, analyzing the association between temporary contracts and mortality by sector of employment could be more appropriated than adjusting for this variable.

In Italy, reforms in the labor market legislation followed the European trend. Changes in the legislation were carried out during the last decades, starting with the "Treu law" in 1997. This reform introduced temporary contracts and modified regulation of fixed-term contracts, producing more flexibility, and consequently more instability in the labor market. Thus, the aim of

this study was to assess the association between temporary contracts and all-cause and causespecific mortality among a cohort of employees between 2001 and 2015 in Rome. Our hypothesis was that the association between temporary contracts and mortality could be stronger in sectors characterized by manual work.

#### METHODS

## **Study Design**

We used the Rome Longitudinal Study, the administrative cohort of residents in Rome who filled in the 2001 population census. The study, which has been already described, included all subjects who were not living in institutions on the census reference day, 21 Oct 2001.[15-17] We followed the subjects using record-linkage procedures with administrative databases, under strict control to protect individual privacy. We used the Municipal Registry for vital status and migration, and Mortality Registry for the cause of death (coded according to the International Classification of Disease, 9<sup>th</sup> Revision, ICD-9). The follow-up started on the census reference day, and ended on the day of death, of migration from Rome, or 31 Dec 2015, whichever came first. The Rome Longitudinal Study was part of the National Statistical Program 2019 and was approved by the Italian Data Protection Authority.

#### Setting and participants

Rome is the capital of Italy, and it is the largest Italian city with about 2.5 million inhabitants on a surface of 1,290 Km<sup>2</sup> at 2001 census.

In this study, we selected all employees aged 25-65 years at baseline (78% of the employed population).

#### Patient and public involvement

Patient involvement in the study was not possible, as individual contact information were not available because of privacy restrictions. Due to the relevance of the topic, the purpose is to disseminate study results to both population and policy-makers, in order to implement health promotion and prevention strategies in temporary workers of specific economic sectors.

#### Outcomes

We analyzed all-cause mortality, cardiovascular mortality (ICD-9 codes 390–459), and accidental mortality (ICD-9 codes 800–999).

#### Temporary employment, sector of employment, and other variables

The census included several information regarding the occupation for the population aged 15 years or more: occupational status, a binary variable identifying employees and self-employed, the sector of employment, and for employees only, the distinction between temporary and permanent contracts.

The sector of employment was categorized in 28 categories grouped in seven groups, named macro-sectors. The first group was "Fishing and Agriculture" and included agriculture, hunting or forestry, and fishing or fish farming. The second macro-sector was "Industry". It included coal mining and oil extraction; food industry; textile and leather industry; wood, wood products industry printing and publishing; refinery, pharmaceutical, chemical, rubber, and plastic industry; non-metal mineral (glass and cement) industry; processing of minerals, steel industry, engineering industry, electronics, and transportation equipment manufacturing; manufacture of furniture; production and distribution of electricity, water, and gas. The third was "Building Constructions" comprising public works and installation services in buildings. The fourth was "Sales and Transports". It included sale, maintenance, and repair of motor vehicles, sale of fuel; wholesale trade and intermediaries of trade; retail trade; hotels, camping, bars, and restaurants; transportation (public and private), warehousing, post, and telecommunications. The fifth was "Credit, insurances and services", comprising credit, insurance, monetary and financial intermediation; IT, research and development; professional and consulting activities, real estate, and rental. The sixth was "Social Services", local and national public administration; public and private education and training; public and private health and social assistance; political and trade union organizations; recreational, cultural, and sports activities; other service activities; domestic services for families and institutions. The seventh and final group was "International organizations".

Among other census variables we selected gender, date of birth, level of education (coded as low for junior high school or less, medium for high school, and high for university or more), and place of birth (Rome, Italy, and abroad).

## **Statistical analyses**

We computed sex-specific crude mortality rates by age class, type of contract, level of education, and place of birth. We used Cox proportional hazard models to investigate the association between type of contact (temporary vs. permanent employee) and total and causespecific mortality in men and women, overall and by sector of employment. We used time of follow-up as time axis and we stratified the baseline hazard function by age. We tested for interaction between temporary contract and sector of employment using the log-likelihood ratio test.

As additional analyses, we performed the Cox regression stratifying the baseline hazard function by age, level of education, and place of birth.

As a sensitivity analysis, we performed Cox proportional hazard models to investigate the association between type of contact and mortality until 31 December 2006, allowing only five years of follow-up, under the hypothesis that the information on temporary employment at 2001 census could be more reliable in the first years after the census.

# RESULTS

The cohort included in the study was composed by 597,834 employees aged between 25 and 65 years (53.6% men and 46.4% women), followed for a mean of 12.9 years resulting in a total of 7,712,058 person-years.

Table 1 shows the main socio-demographic characteristics, overall, and cause-specific mortality of the study population. Women had a higher proportion of temporary contracts than men (13.3% vs 9.6%) and were more educated than men (26.5% vs 21.9% high educational level). More than one-third of the employees were born outside Rome, and 4.8% of men and 6.1% of women were born abroad. In the period of interest, there were 21,136 deaths (35.1 and 18.8 per 10,000 person-years in men and women respectively). In men and women, cardiovascular deaths accounted for 26.5% and 14.6% of all deaths, respectively, whereas accidental deaths for 6.2% in men and 3.8% in women. Accidental mortality was almost twice for temporary compared to permanent workers in both men (10.9% vs 5.8%) and women (6.7% vs 3.6%).

Main characteristics by occupational sectors for men and women are shown in Supplementary Material. In men (Table S1), the macro-sector with the highest percentage of temporary employees was fishing and agriculture (14.7%). The sector with the highest proportion of temporary workers was recreational, cultural, and sports activities, within the macro-category of social services, with 27.1%. Table S1 highlights the differences among sectors in terms of socioeconomic position and origins. The education sector had the highest proportion of highly y t. . were h. . d by international o. educated employees (62.9%), followed by the health and social assistance sector (45.7%), whereas the sectors with the lowest proportion were hotels, bars, and restaurants (4.8%) and domestic services (4.9%). The proportion of foreigners varied among sectors with the highest percentage in domestic services (32.1%) followed by international organizations (20.6%).

#### **BMJ** Open

Women showed higher percentages of temporary contracts than men in all macro-sectors (Table S2). In women, the macro-sectors with the highest percentage of temporary employees were fishing and agriculture (20.4%), international organizations (17.6%), and sales and transport (14.6%). The lowest proportion was in social services (12.5%). However, in this macro-sector, there was great variability, with the percentage of temporary workers ranging between 31.2% of recreational, cultural and sporting activities, and 5.9% of local, national, and public administration.

Table 2 shows the association between temporary employment and mortality overall and by macro-sector of employment in men and women. Age-adjusted Cox regression models showed greater overall mortality risk for temporary workers in men (HR 1.16, 95%CI 1.09-1.24) but not in women (HR 1.03, 95%CI 0.95-1.12). Results of the likelihood ratio test, comparing the models with and without the interaction term between type of contract and sector of employment, were statistically significant in both men (p = 0.04) and women (p = 0.04). Among macro-sectors, industry (HR 1.26, 95%CI. 1.07-1.49), building constructions (HR 1.29, 95%CI 1.08-1.54), and social services (HR 1.11, 95%CI 1.00-1.25) showed greater overall mortality risks in men, whereas women had higher mortality in sales and transports sector (HR 1.23, 95%CI 1.01-1.49). Overall, men had higher cardiovascular mortality in temporary compared to permanent workers (HR 1.29, 95%CI 1.14-1.45), specifically the association was significant in the macro-sectors of sales and transports (HR 1.33, 95%CI 1.05-1.68) and social services (HR 1.26, 95%CI 1.03-1.55). In women, although in several macro-sectors the hazard ratios were greater than one, there was no evidence of association between type of contract and cardiovascular mortality. Temporary workers had higher risk of accidental mortality compared to workers in permanent positions in men (HR 1.27, 95%CI 1.04-1.57), but not in women (HR 1.34, 95%Cl 0.94-1.91).

Table 3 shows the association between temporary employment and overall, cardiovascular, and accidental mortality in men by specific sector of employment. There was an association with

overall mortality, with higher risks in subjects with temporary compared to permanent contracts, in the steel industry sector (HR 1.34, 95%Cl 1.04-1.71) and in the public administration (HR 1.20, 95%Cl 1.01-1.43). Higher cardiovascular mortality risks were found in the sector of production and distribution of electricity, water, and gas (HR 3.85, 1.50-9.83), in the retail and trade sector (HR 1.72, 95%Cl 1.07-2.77), in the sector which includes professional consulting, real estate, and rental (HR 1.98, 95%Cl 1.13-3.49), and public administration (HR 1.56, 95%Cl 1.15-2.11). There was a higher risk for accidental mortality in two sectors: steel industry (HR 2.01, 1.04-3.87), and wholesale trade and intermediaries of trade (HR 4.48, 1.52-13.25) with wide confidence intervals due to the small number of deaths. Since there was no evidence of association between type of contract and overall mortality in women, we did not investigate the possible association in specific sectors.

Supplementary Table S3 shows the results from Cox regression models adjusted for age and level of education, and then for age, level of education, and place of birth. The results on the association between temporary employment and mortality in men and women were similar to those presented in Table 2.

The sensitivity analysis conducted on a follow-up from 2001 to 2006, confirmed the results on overall and cardiovascular mortality in men. Results on accidental mortality were based on 345 cases and were not statistically significant. Supplementary Table S4 shows the results of the association between temporary employment and overall mortality by macro-sectors ending the follow-up in December 2006. The results were similar, although the scarcity of events in the first five years of follow-up did not allow having statistically significant associations.

## DISCUSSION

Our results, based on a cohort of 597,834 employees, showed that having temporary contracts, compared to permanent ones, was associated with greater overall mortality risk in men but not in women. Mortality risks for temporary employees compared to permanent ones varied widely among different economic sectors. In men, we found higher risks in industry, building constructions, and social services sectors. In women, we found a higher risk in temporary compared to permanent workers only in sales and transports, mainly due to the strong association in the retail sector.

Differences between men and women were consistent for all considered causes of death and all economic sectors, except for sales and transports. There was considerable agreement between our results and previously published works regarding gender differences in the association between temporary contract and mortality. All the studies that stratified the analysis by gender found stronger associations in men than in women.[11-13]

For both men and women, the analysis of the association between temporary contract and mortality by sector of employment showed that most hazard ratios were greater than one. The risk for temporary employment was generally higher in sectors where less-skilled employees were more represented. Particularly in men, mortality was higher in sectors in which manual workers are predominant, such as industry and building constructions. One possible explanation could be that temporary workers employed in these sectors might be exposed to specific risks. Indeed, it is well known that employees working in specific economic sectors may be exposed to hazards and behavioral risks.[18,19] Furthermore, it is well established that, compared to permanent workers, temporary ones experience worse job quality,[20] and less use of personal protective equipment,[21] as well as less training and information about work environment and occupational risks.[22,23] Therefore, it could be hypothesized that these conditions impact mostly on temporary workers employed in specific sectors. In men, the association between temporary contracts and mortality was also evident in the sector of public administration.

A study conducted in Rome that analyzed the association between occupational status and mortality found higher mortality for cardiovascular disease and accidental causes in unemployed

Page 17 of 31

#### **BMJ** Open

compared to employees.[17] Possible explanations provided by the authors are the prevalence of risky behaviors and habits (smoking or unhealthy diet) among unemployed, as well as the "status syndrome" theory that hypothesizes a link between lack of control and low social participation and disease risk. Temporary workers may share some of the same risky conditions of unemployed. A study found higher mortality in temporary compared to permanent workers for smoking and alcohol related cancers.[13] Furthermore, temporary workers can frequently experience periods of unemployment. Therefore, some of the risk factors of unemployment may have an impact also on temporary employment regarding cardiovascular and accidental mortality.

In general, temporary employment includes all forms of no open-ended contracts, such as fixed-term, temporary-agency, apprenticeship, seasonal, and casual works. The majority of these forms of employment may share different dimensions of precariousness, such as job insecurity, low wages, and social protection. All these factors are proposed as possible pathways linking temporary employment to negative health outcomes.[24] Nevertheless, a general negative impact was found on self-reported health,[2,25] although some studies are not consistent with this result.[26] There is a large consensus regarding the negative impact on mental health,[10] while for occupational injuries a recent meta-analysis showed no conclusive results.[27] Studies on mortality showed that the strength of the association varies with the type of temporary contract,[11] and that the risk is higher only for involuntary and not satisfied temporary workers.[14]

Globally, the studies on the association between temporary employment and mortality are limited and they were conducted all in North European countries. It is noteworthy that the impact of precariousness on health outcomes could depend also on contextual factors, such as the percentage of precarious employment and the social policies in the country.[28] Our study was the first to analyze the association between mortality and type of contract in Italy. According to the Italian Institute of Statistics, the percentage of temporary employment in Italy has increased in the last decades, ranging from a mean of 11.8% of the total dependent employee in 2004 to a mean of 17.0% in 2019.[29] Rising in temporary contracts was mainly explained by the structural reforms that increased flexibility in the labor market over the last decades,[30] as well as the Great Recession in 2008. Regarding gender differences in contracts type, our data based on Rome population are in agreement with national data, with a higher rate of temporary workers in

women than in men. In the population of Rome, the higher percentage of women with temporary contracts in our study can be added to previous results showing that women had a higher percentage of unemployment than men.[17]

Our study had some limitations. First, the type of contract was evaluated only at the beginning of the follow-up, i.e. 2001. However, there is substantial agreement between the principal and the sensitivity analyses, although the smaller number of deaths in the latter reduced the significance of the associations. Second, there was a lack of information on employees' health and behavioral risk factors. In particular, it is possible that the health status influenced the probability of having a permanent employment, determining a selection bias. Third, since the cohort was followed from 2001 to 2015, the data could be considered dated. However, the 2001 census was the last census that collected information on job and type of contract for the whole population. Therefore, it is the last census that allows analyzing different economic sectors separately. Finally, since 84,084 subjects migrated during the follow-up, the censoring for migration from Rome could have introduced a bias. However, a previous study on education and mortality used an inverse probability approach to account for migration and did not find differences in results from the traditional survival analysis.[16]

In conclusion, our results point out that temporary contracts should be considered as an important determinant of health in particular for workers employed in specific economic sectors. Furthermore, the well-known heterogeneity in the temporary employees was confirmed by our study throughout the different economic sectors. These results highlight the importance to perform studies on health outcomes in temporary workers focusing on different economic sectors to better understand individual, work-related and contextual factors linking temporary contracts and mortality risk. Future research should be conducted to confirm these results and to evaluate differences among countries with different labor market settings.

# Contributors

AN and GC conceived the study, drafted the manuscript and were responsible for the final version of the manuscript. GC handled the permissions and data collection. AN, LDB and GC handled the data management and analyses. NA and MD critically revised the manuscript for important intellectual content. All authors reviewed, read and approved the final manuscript.

# Funding

The authors have not received specific funding from any agency in the public, commercial or notfor-profit sectors.

# **Competing interests**

None declared.

# Patient consent for publication

Not required.

# Data availability statement

Data reported in the manuscript are not publicly available because of stringent legal restrictions regarding privacy policy on personal information in Italy (national legislative decree on privacy policy n. 196/30 June 2003). All data presented in the study are stored by the Department of Epidemiology-Lazio Regional Health Service and only the research team and related Institutions have access to the data. Interested researchers can contact the following persons to request the data: Nera Agabiti (n.agabiti@deplazio.it).

# **Ethics** approval

The Rome Longitudinal Study is approved by the Italian Data Protection Authority (G.U. 16-07-2019 n.165. pag.26. available at:

Results Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially
		eligible, examined for eligibility, confirmed eligible, included in the study,
		completing follow-up, and analysed
		(b) Give reasons for non-participation at each stage
		(c) Consider use of a flow diagram
Descriptive	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and
data		information on exposures and potential confounders
		(b) Indicate number of participants with missing data for each variable of interest
		(c) Cohort study—Summarise follow-up time (eg, average and total amount)
Outcome data	15*	Cohort study-Report numbers of outcome events or summary measures over time
		Case-control study-Report numbers in each exposure category, or summary
		measures of exposure
		Cross-sectional study—Report numbers of outcome events or summary measures
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and
		their precision (eg, 95% confidence interval). Make clear which confounders were
		adjusted for and why they were included
		(b) Report category boundaries when continuous variables were categorized
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a
		meaningful time period
Other analyses	17	Report other analyses done-eg analyses of subgroups and interactions, and
		sensitivity analyses
Discussion		
Key results	18	Summarise key results with reference to study objectives
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or
		imprecision. Discuss both direction and magnitude of any potential bias
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations,
		multiplicity of analyses, results from similar studies, and other relevant evidence
Generalisability	21	Discuss the generalisability (external validity) of the study results
Other information	on	
Funding	22	Give the source of funding and the role of the funders for the present study and, if
		applicable, for the original study on which the present article is based

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). # ABSTRACT

# Objective

Precarious employment is characterized by instability, lack of protection, and economic vulnerability. The objective of this study was to assess the association between temporary contracts and mortality.

# Design

Cohort study

# Setting

Rome, Italy

# Participants

All employees, aged 25-65 years, from the Rome Longitudinal Study, followed from 21 Oct 2001 to the first date among death, migration from Rome, or 31 Dec 2015.

Primary and secondary outcome measures

We investigated all-cause, cardiovascular, and accidental mortality. We considered gender, age, place of birth, education, temporary vs. permanent contract, and sector of employment. We used Cox models to investigate the association between type of contract and total, cardiovascular and accidental mortality in men and women, overall and by employment sector.

# Results

We analyzed 597,834 subjects. The proportion of temporary contracts varied by gender (9.6% in men and 13.3% in women) and by employment sector, ranging from 4.5% (public administration) to 27% (recreational, cultural, sports activities) in men. During the study period 21,136 subjects died. Men with temporary contracts, compared to those with permanent positions, had greater overall mortality risk (HR=1.16, 95%CI: 1.09-1.24), cardiovascular mortality (HR=1.29, 95%CI: 1.14-1.45), and accidental mortality (HR=1.27, 95%CI: 1.04-1.57). In men, the association varied widely among different economic sectors, with greater risks in the industry, building constructions, and social services sectors. In women, there was no evidence of association between temporary contracts and mortality. A statistically significant association between temporary contracts and mortality in women was found in the sector of sales and transports only.

# Conclusions

Temporary work should be considered a determinant of health, particularly for specific economic sectors.

Keywords: temporary employment, longitudinal study, mortality, vulnerability.

# Strengths and limitations of this study

- The study was based on 597,834 employees aged between 25 and 65 years residents in a • metropolitan area, followed for 14 years.
- Census information linked to health data allowed a detailed analysis of health outcomes related to temporary work.
- The information on the sector of employment allowed to investigate health outcomes ecifi . job histor . ation on employ. related to temporary work in specific sectors.
- The lack of information about job histories was a strong limit of our study. •
- There was a lack of information on employees' health and behavioral risk factors. •

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

### INTRODUCTION

During the last decades, increased flexibility in the labor market led to the spread of various forms of non-standard and precarious employment in Europe.[1] Due to the growth of evidence on the potential implications on health status, precariousness has been suggested as an emerging social determinant of health.[2] Some studies showed a social gradient in precarious contracts regarding the educational level and job type.[3,4] In addition, a higher proportion of precarious contracts was reported among women,[5] young adults,[1] and migrants.[6]

Despite the growing body of research, some concerns remain about the definition of precarious employment. According to the seminal work of Rodgers and Rodgers,[7] precariousness is a complex construct that encompasses different dimensions involving employment instability and insecurity, lack of protection, and economic vulnerability. Although some multidimensional methods have been developed to assess precariousness,[8,9] in public health research, it is frequent to focus on a specific domain using a one-dimensional approach. Within these domains, temporary employment, an objective measure of precariousness, is one of the most investigated.[10]

Few studies analyzed the effect of type of contract on mortality, showing an association between temporary contracts and mortality in specific subgroups of workers.[11-14] However, all mortality studies were conducted in Nordic European countries, and none investigated the impact of temporary contracts among different economic sectors. As the rate of temporary contracts may vary widely among economic sectors, the latter were evaluated as confounding factors.[13] Due to the worse working conditions of temporary employees, it is reasonable to hypothesize a joint effect between sector-related and contract-related health risks. Therefore, analyzing the association between temporary contracts and mortality by employment sector could be more appropriate than adjusting for this variable.

In Italy, reforms in the labor market legislation followed the European trend. Changes in the legislation were carried out during the last decades, starting with the "Treu law" in 1997. This reform introduced temporary contracts and modified regulation of fixed-term contracts, producing more flexibility and consequently more instability in the labor market. Thus, this study

aimed to assess the association between temporary contracts and all-cause and cause-specific mortality among a cohort of employees between 2001 and 2015 in Rome. We hypothesized that the association between temporary contracts and mortality could be stronger in sectors characterized by manual work, where uncertainty due to the temporary contracts might be a proxy of precariousness more than in non-manual sectors. Also, temporary manual workers might use personal protective equipment less than workers with permanent positions.

#### **METHODS**

#### **Study Design**

We used the Rome Longitudinal Study, the administrative cohort of residents in Rome who filled in the 2001 population census. The study, which has been already described, included all subjects who were not living in institutions on the census reference day, 21 Oct 2001.[15-17] We followed the subjects using record-linkage procedures with administrative databases, under strict control to protect individual privacy. We used the Municipal Registry for vital status and migration and Mortality Registry for the cause of death (coded according to the International Classification of Disease, 9<sup>th</sup> Revision, ICD-9). The follow-up started on the census reference day and ended on the day of death, of migration from Rome, or 31 Dec 2015, whichever came first. The Rome Longitudinal Study was part of the National Statistical Program 2019 and was approved by the Italian Data Protection Authority.

#### Setting and participants

Rome is the capital of Italy, and it is the largest Italian city with about 2.5 million inhabitants on a surface of 1,290 Km<sup>2</sup> at 2001 census.

In this study, we selected all employees aged 25-65 years at baseline (78% of the employed population).

#### Patient and public involvement

Patient involvement in the study was not possible, as individual contact information was unavailable because of privacy restrictions. However, due to the topic's relevance, the purpose is to disseminate study results to both population and policy-makers, to implement health promotion and prevention strategies in temporary workers of specific economic sectors.

# Outcomes

We analyzed all-cause mortality, cardiovascular mortality (ICD-9 codes 390–459), and accidental mortality (ICD-9 codes 800–999).

# Temporary employment, sector of employment, and other variables

The census included a large amount of information regarding the occupation for the population aged 15 years or more: occupational status, a binary variable identifying employees and self-employed, the sector of employment, and for employees only, the distinction between temporary and permanent contracts.

The sector of employment was categorized in 28 categories grouped in seven groups, named macro-sectors. Sectors were classified as in the 2001 Italian census by the Italian National Institute of Statistics (ISTAT).[18]

Among other census variables, we selected gender, date of birth, level of education (coded as low for junior high school or less, medium for high school, and high for university or more), and place of birth (Rome, Italy, and abroad).

# **Statistical analyses**

We computed sex-specific crude mortality rates by age class, type of contract, level of education, and place of birth. We used Cox proportional hazard models to investigate the association between type of contact (temporary vs. permanent employee) and total and causespecific mortality in men and women, overall and by employment sector. We used time of followup as time axis and stratified the baseline hazard function by age. We tested for interaction between temporary contract and employment sector using the log-likelihood ratio test.

# **Additional analyses**

As additional analyses, we performed the Cox regression stratifying the baseline hazard function by age, level of education, and place of birth.

As a sensitivity analysis, we performed Cox proportional hazard models to investigate the association between type of contact and mortality until 31 December 2006, allowing only five years of follow-up, under the hypothesis that the information on temporary employment at 2001 census could be more reliable in the first years after the census.

Assuming that temporary workers are more likely to migrate in search of a better position, we used an inverse probability weighting approach to handle missing information on deaths due to lost to follow-up due to migration.[19] First, we estimated sex-stratified probability (P) of non-emigration as a function of age, education, type of contract, and place of birth using logistic regression models. Then, we estimated the probability (P') of non-emigration as a function of age only to calculate stabilized weights (W) as P'/P. Finally, we performed weighted Cox regression models on non-migrants using the weights W.

Since the type of contract might partly reflect the well-known health differences in occupational classes, we further analyzed the association between temporary employment and mortality for each occupational class, categorized as manual workers, sale or service workers, low-skill non-manual workers and high-skill non-manual workers.

#### RESULTS

The cohort included in the study was composed by 597,834 employees aged between 25 and 65 years (53.6% men and 46.4% women), followed for a mean of 12.9 years resulting in a total of 7,712,058 person-years.

Table 1 shows the main socio-demographic characteristics, overall, and cause-specific mortality of the study population. The percentage of temporary workers was higher in the youngest age class (20.2% in men and 24.6% in women), in the lower educational level (10.2% in men and 13.3% in women) and in people born abroad (14.0% in men and 18.4% in women). Women had a higher proportion of temporary contracts than men (13.3% vs. 9.6%) and were more educated than men (26.5% vs. 21.9% high educational level). More than one-third of the employees were born outside Rome, and 4.8% of men and 6.1% of women were born abroad. In the period of interest, there were 21,136 deaths (35.1 and 18.8 per 10,000 person-years in men and women, respectively). In men and women, cardiovascular deaths accounted for 26.5% and 14.6% of all deaths, respectively, whereas accidental deaths for 6.2% in men and 3.8% in women. Accidental mortality was almost twice as high for temporary compared to permanent workers in both men (10.9% vs. 5.8%) and women (6.7% vs. 3.6%) (not shown in table).

AC accidental

CMR crude mortality rate per 10,000 person-years

Main characteristics by occupational sectors for men and women are shown in Supplementary Material. In men (Table S1), the macro-sector with the highest percentage of temporary employees was fishing and agriculture (14.7%). The sector with the highest proportion of

temporary workers was recreational, cultural, and sports activities, within the macro-category of social services, with 27.1%. Table S1 highlights the differences among sectors in terms of socioeconomic position and origins. The education sector had the highest proportion of highly educated employees (62.9%), followed by the health and social assistance sector (45.7%), whereas the sectors with the lowest proportion were hotels, bars, and restaurants (4.8%) and domestic services (4.9%). The proportion of foreigners varied among sectors, with the highest percentage in domestic services (32.1%) followed by international organizations (20.6%). Women showed higher percentages of temporary contracts than men in all macro-sectors (Table S2). In women, the macro-sectors with the highest rate of temporary employees were fishing and agriculture (20.4%), international organizations (17.6%), and sales and transport (14.6%). Conversely, the lowest proportion was in social services (12.5%). However, in this macro-sector, there was great variability, with the percentage of temporary workers ranging between 31.2% of recreational, cultural and sporting activities and 5.9% of local, national, and public administration.

Table 2 shows the association between temporary employment and mortality overall and by employment macro-sector in men and women. Age-adjusted Cox regression models showed greater overall mortality risk for temporary workers in men (HR 1.16, 95%CI 1.09-1.24) but not in women (HR 1.03, 95%CI 0.95-1.12). The likelihood ratio tests, comparing the models with and without the interaction term between type of contract and sector of employment, were statistically significant in both men (p = 0.04) and women (p = 0.04). Among macro-sectors, industry (HR 1.26, 95%CI. 1.07-1.49), building constructions (HR 1.29, 95%CI 1.08-1.54), and social services (HR 1.11, 95%CI 1.00-1.25) showed greater overall mortality risks in men, whereas women had higher mortality in sales and transports sector (HR 1.23, 95%CI 1.01-1.49). Overall, in men, temporary workers had higher cardiovascular mortality in temporary than those with permanent positions (HR 1.29, 95%CI 1.14-1.45), particularly in the macro-sectors of sales and transports (HR 1.33, 95%CI 1.05-1.68) and social services (HR 1.26, 95%CI 1.03-1.55). In women, although the hazard ratios were greater than one in several macro-sectors, there was no evidence of an association between type of contract and cardiovascular mortality. Temporary workers had a higher risk of accidental mortality than workers in permanent positions in men (HR 1.27, 95%CI 1.04-1.57), but not in women (HR 1.34, 95%CI 0.94-1.91).

Table 3 shows the association between temporary employment and overall, cardiovascular, and accidental mortality in men by specific employment sector. There was an association with

6/bmjopen-202 . .... ... -

 overall mortality, with higher risks in subjects with temporary compared to permanent contracts, in the steel industry sector (HR 1.34, 95%Cl 1.04-1.71) and in the public administration (HR 1.20, 95%Cl 1.01-1.43). Higher cardiovascular mortality risks were found in the sector of production and distribution of electricity, water, and gas (HR 3.85, 1.50-9.83), in the retail and trade sector (HR 1.72, 95%Cl 1.07-2.77), in the sector which includes professional consulting, real estate, and rental (HR 1.98, 95%Cl 1.13-3.49), and public administration (HR 1.56, 95%Cl 1.15-2.11). There was a higher risk for accidental mortality in two sectors: steel industry (HR 2.01, 1.04-3.87) and wholesale trade and intermediaries of trade (HR 4.48, 1.52-13.25) with wide confidence intervals due to the small number of deaths. Since there was no evidence of an association between type of contract and overall mortality in women, we did not investigate the possible association in specific sectors.

Supplementary Table S3 shows the results from Cox regression models adjusted for age and level of education, and then for age, level of education, and place of birth. Adjusting for the level of education and place of birth slightly reduced the HR for all statistically significant results except for public service in men and sales and transport in women, which presented an increase.

The sensitivity analysis conducted with a follow-up from 2001 to 2006 confirmed the results on overall and cardiovascular mortality in men. Results on accidental mortality were based on 345 cases and were not statistically significant. Supplementary Table S4 shows the results of the association between temporary employment and overall mortality by macro-sectors ending the follow-up in December 2006. The results were similar, although the scarcity of events in the first five years of follow-up did not allow having statistically significant associations. There were no differences in HRs for overall and cause-specific mortality using the inverse probability approach: for overall mortality the HRs of temporary vs. permanent contracts were 1.17 (95%CI 1.10-1.25) and 1.04 (95%CI 0.95-1.14) for men and women, respectively.

Supplementary Table S5 shows the results of the association between temporary employment and overall mortality by type of work. Manual and sale or service workers with temporary contracts showed significantly higher overall mortality than those with permanent contracts (manual: HR 1.16; 95%Cl 1.05-1.28; sale or service: HR 1.22; 95%Cl 1.02-1.46). However, it should be noted that HRs > 1 were found in all occupational classes, although without reaching statistical significance. Furthermore, high-skill non-manual workers with temporary contracts showed significantly higher cardiovascular mortality compared to high-skill non-manual workers with permanent contracts (HR 1.34; 95%Cl 1.06-1.70).

### DISCUSSION

Our results, based on a cohort of 597,834 employees, showed that having temporary contracts, compared to permanent ones, was associated with greater overall mortality risk in men but not in women. Mortality risks for temporary employees compared to permanent ones varied widely among different economic sectors. In men, we found higher risks in the industry, building constructions, and social services sectors. In women, we found a higher risk in temporary compared to permanent workers only in sales and transports, mainly due to the strong association in the retail sector.

Differences between men and women were consistent for all considered causes of death and all economic sectors, except for sales and transport. There was considerable agreement between our results and previously published works regarding gender differences in the association between temporary contracts and mortality. All the studies that stratified the analysis by gender found stronger associations in men than in women.[11-13]

For both men and women, the analysis of the association between temporary contracts and mortality by sector of employment showed that most hazard ratios were greater than one. The risk for temporary employment was generally higher in sectors where less-skilled employees were more represented. Particularly in men, mortality was higher in sectors in which manual workers are predominant, such as industry and building constructions. One possible explanation could be that temporary workers employed in these sectors might be exposed to specific risks. Indeed, it is well known that employees working in specific economic sectors may be exposed to hazards and behavioral risks.[20,21] Furthermore, it is well established that, compared to permanent workers, temporary ones experience worse job quality,[22] and less use of personal protective equipment,[23] as well as less training and information about the work environment and occupational risks.[24,25] Therefore, it could be hypothesized that these conditions impact mostly on temporary workers employed in specific sectors. In men, the association between temporary contracts and mortality was also evident in the sector of public administration. This association is somewhat difficult to explain. It has to be considered that, due to the high number of comparisons, it could be possible that some of the associations can be due to chance.

A study conducted in Rome that analyzed the association between occupational status and mortality found higher mortality for cardiovascular disease and accidental causes in unemployed compared to employees.[17] Possible explanations provided by the authors are the prevalence of risky behaviors and habits (smoking or unhealthy diet) among the unemployed and the "status syndrome" theory that hypothesizes a link between lack of control and low social participation and disease risk. Temporary workers may share some of the same risky conditions of unemployed. A study found higher mortality in temporary compared to permanent workers for smoking and alcohol-related cancers.[13] Furthermore, temporary workers can frequently experience periods of unemployment. Therefore, some of the risk factors of unemployment may have an impact also on temporary employment regarding cardiovascular and accidental mortality.

In general, temporary employment includes all forms of no open-ended contracts, such as fixed-term, temporary-agency, apprenticeship, seasonal, and casual works. Most of these forms of contracts may share different dimensions of precariousness, such as job insecurity, low wages, and social protection. These factors are proposed as possible pathways linking temporary employment to adverse health outcomes.[26] Nevertheless, a negative impact was generally found on self-reported health,[2,27] although some studies are not consistent with this result.[28] There is a large consensus regarding the negative impact on mental health,[10] while for occupational injuries, a recent meta-analysis showed no conclusive results.[29] Studies on mortality showed that the strength of the association varies with the type of temporary contract,[11] and that the risk is higher only for involuntary and not satisfied temporary workers.[14]

It should be considered that type of contract might partly reflect the well-known health differences in occupational class. However, the additional analysis showed differences for both manual and high-skill non-manual workers. Therefore, temporary contacts and job type seem to assess distinct socioeconomic job-related domains, with temporary contacts showing different impacts on mortality risk among the occupational classes.

Globally, the studies on the association between temporary employment and mortality are limited, and they were all conducted in North European countries. It is noteworthy that the impact of precariousness on health outcomes could also depend on contextual factors, such as the percentage of precarious employment and the social policies in the country.[30] Our study was the

Page 17 of 32

#### **BMJ** Open

first to analyze the association between mortality and type of contract in Italy. According to the Italian Institute of Statistics, the percentage of temporary employment in Italy has increased in the last decades, ranging from a mean of 11.8% of the total dependent employee in 2004 to a mean of 17.0% in 2019.[31] Rising in temporary contracts was mainly explained by the structural reforms that increased flexibility in the labor market over the last decades,[32] as well as the Great Recession in 2008. Regarding gender differences in contracts type, our data based on Rome population agrees with national data, with a higher rate of temporary workers in women than in men. In the population of Rome, the higher percentage of women with temporary contracts in our study can be added to previous results showing that women had a higher rate of unemployment than men.[17]

Our study had some limitations. First, the type of contract was evaluated only at the beginning of the follow-up, i.e., 2001. However, there is substantial agreement between the principal and the sensitivity analyses, although the smaller number of deaths in the latter reduced the significance of the associations. Second, there was a lack of information on employees' health and behavioral risk factors. In particular, it is possible that the health status influenced the probability of having permanent employment, determining a selection bias. Another potential selection bias could be the differential migration from Rome in temporary vs. permanent workers. However, assuming the absence of unmeasured confounders, we used an inverse probability weighting approach to handle missing information on deaths due to lost to follow-up due to migration, obtaining weighted HRs similar to those presented. Finally, since the cohort was followed from 2001 to 2015, the data could be considered dated. However, the 2001 census was the last census that collected information on jobs and type of contracts for the whole population. Therefore, it is the last census that allows analyzing different economic sectors separately.

In conclusion, our results point out that temporary contracts should be considered as an important determinant of health, in particular for workers employed in specific economic sectors. At the health and work policy level, this means that major efforts should be made to reduce precariousness. As a determinant of health, temporary work should be taken into account also in the development of national and local prevention plans, providing specific sector recommendations for both employers and occupational medicine professionals. Prevention strategies, such as information and training should also be implemented.

> The well-known heterogeneity in the temporary employees was confirmed by our study throughout the different economic sectors. These results highlight the importance of performing studies on health outcomes in temporary workers focusing on various economic sectors to understand better individual, work-related, and contextual factors linking temporary contracts and mortality risk. Future research should confirm these results and evaluate differences among countries with different labor market settings.

STROBE Statement-checklist of items that should be included in reports of observational studies

	Item No	Recommendation	Pag No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or	1
		the abstract	
		(b) Provide in the abstract an informative and balanced summary of what	2
		was done and what was found	
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of	5
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~		recruitment, exposure, follow-up, and data collection	
Participants	6	(a) Cohort study—Give the eligibility criteria, and the sources and	5
- w	0	methods of selection of participants. Describe methods of follow-up	
		<i>Case-control study</i> —Give the eligibility criteria, and the sources and	
		methods of case ascertainment and control selection. Give the rationale	
		for the choice of cases and controls	
		<i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and	
		methods of selection of participants	
		(b) Cohort study—For matched studies, give matching criteria and	
		number of exposed and unexposed	
		<i>Case-control study</i> —For matched studies, give matching criteria and the	
		number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders,	6
		and effect modifiers. Give diagnostic criteria, if applicable	
Data sources/	8*	For each variable of interest, give sources of data and details of methods	5,6
measurement	-	of assessment (measurement). Describe comparability of assessment	- , -
		methods if there is more than one group	
Bias	9	Describe any efforts to address potential sources of bias	6, 7
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If	6
		applicable, describe which groupings were chosen and why	
Statistical methods	12	( <i>a</i> ) Describe all statistical methods, including those used to control for	6,7
		confounding	
		(b) Describe any methods used to examine subgroups and interactions	6
		(c) Explain how missing data were addressed	5
		(d) Cohort study—If applicable, explain how loss to follow-up was	5, 7
		addressed	16
		<i>Case-control study</i> —If applicable, explain how matching of cases and	
		controls was addressed	
		<i>Cross-sectional study</i> —If applicable, describe analytical methods taking	
		account of sampling strategy	

Continued on next page

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially	
		eligible, examined for eligibility, confirmed eligible, included in the study,	
		completing follow-up, and analysed	
		(b) Give reasons for non-participation at each stage	
		(c) Consider use of a flow diagram	
Descriptive	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and	
data		information on exposures and potential confounders	
		(b) Indicate number of participants with missing data for each variable of interest	
		(c) Cohort study—Summarise follow-up time (eg, average and total amount)	
Outcome data	15*	Cohort study—Report numbers of outcome events or summary measures over time	
		Case-control study-Report numbers in each exposure category, or summary	
		measures of exposure	
		Cross-sectional study—Report numbers of outcome events or summary measures	
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and	
		their precision (eg, 95% confidence interval). Make clear which confounders were	
		adjusted for and why they were included	
		(b) Report category boundaries when continuous variables were categorized	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a	
		meaningful time period	
Other analyses	17	Report other analyses done-eg analyses of subgroups and interactions, and	
		sensitivity analyses	
Discussion			
Key results	18	Summarise key results with reference to study objectives	
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or	
		imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations,	
		multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	
Other informati	on		
Funding	22	Give the source of funding and the role of the funders for the present study and, if	
		applicable, for the original study on which the present article is based	

applicable, for the original study on which the present article is based

\*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

**Note:** An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). Information on the STROBE Initiative is available at www.strobe-statement.org.
