Abstract

Objectives: Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.

Methods: Based on the data from 77 county-level public general hospitals (CPGHs) in Shanxi Province, China, from 2013-2018, we applied the meta-frontier and SBM-undesirable DEA model to measure the CPGHs' medical service efficiency with or without medical quality constraints and evaluate the effects of the new medical reform to explore the utilization of health resources and look for ways to improve the CPGHs' medical service efficiency.

Results : The results of this study showed that the efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This

1
2
3
4 showed that ignoring medical quality constraints will result in lower efficiency and
5
6 lower health resource utilization for high medical quality hospitals. The medical service
7
8 efficiency of CPGHs differs greatly among different regions. Under the meta-frontier,
9
10 the hospitals in the central region had the highest efficiency (efficiency score 0.70),
11
12 followed by those in the south (efficiency score 0.63), and the hospitals in the north had
13
14 the lowest efficiency (efficiency score 0.54).
15
16
17
18

19 **Conclusion:** To improve CPGHs' medical service efficiency, the government should
20
21 increase investment in the northern region, and hospitals should improve the
22
23 management level and allocate human resources rationally.
24

33
34

35 **Strengths and limitations of this study**

36
37 Firstly, we applied the Meta-frontier and SBM-undesirable DEA models to
38
39 evaluate the medical service efficiency, which effectively solved the problem that the
40
41 efficiency score of hospitals were not on the same production frontier. Secondly,
42
43 medical quality index was set as an output indicators in this study, which means that
44
45 the hospitals should not only focus on the number of patients, but also focus on the
46
47 medical quality. Thirdly, only 77 hospitals were chosen in one province, so the
48
49 extrapolation of this study may be limited.

Background

1
2
3
4 In March 2009, the Chinese government started a new medical reform. Since the
5
6 implementation of the medical reform, China has made great achievements in
7
8 expanding medical security services [1,2]. The government has vigorously developed
9
10 primary medical and health services and strived to improve the fairness of the health
11
12 service distribution [3]. However, the distribution of health resources in China is still
13
14 unreasonable, and health resources are scarce [4]. High-quality medical resources are
15
16 mainly concentrated in cities, leading to a significant medical quality gap between
17
18 urban and rural hospitals [5-7]. Additionally, patients prefer to choose urban hospitals,
19
20 which leads to the idleness of rural hospital resources [8]. Health resource waste and
21
22 shortage issues have seriously restricted the service ability of medical and health
23
24 institutions and led to low medical efficiency [9]. To solve these problems and improve
25
26 the quality of medical services, the government has implemented a series of reforms in
27
28 rural hospitals [1,10]. China's urban and rural medical system is mainly composed of
29
30 urban tertiary hospitals, urban community hospitals, county-level hospitals and
31
32 township health centers [11]. Among them, county-level public general hospitals
33
34 (CPGHs) act as a link in China's urban and rural medical system, and they are the
35
36 leaders of rural health institutions [12 13 14]. Their medical services have a wide range
37
38 of radiation and cover a large population [9]. However, county-level hospitals also have
39
40 problems such as shortages of human resources, low levels of medical services and
41
42 uneven distributions of resources [14-16]. For example, Wu noted that the quality of
43
44 human resources in primary hospitals is not high and the medical service level is poor
45
46 [17]. Jay found that the average resource levels of county-level hospitals in western
47
48

52
53
54
55
56
57
58
59
60

1
2
3
4 China were lower than those in other regions [18]. Therefore, it is very important to
5
6 improve the utilization rate of primary health resources and the medical efficiency of
7
8 county-level hospitals.
9

10
11 In recent years, many scholars have studied the medical efficiency of CPGHs in
12
13 China. Li measured the medical efficiency of 12 CPGHs in Anhui Province and found
14
15 that it has declined year by year; additionally, the medical reform effect of CPGHs was
16
17 not significant [19]. Wang analyzed the medical efficiency of 127 CPGHs in China and
18
19 found that the efficiency of CPGHs still has considerable room for improvement [20].
20
21 Jiang conducted a study of 1105 CPGHs in China and noted that although medical
22
23 reform has increased the scale of hospitals, it has not improved the medical efficiency
24
25 of CPGHs [9]. Other scholars' studies have also shown that the medical efficiency of
26
27 CPGHs has room for improvement [12,21,22].
28
29
30
31
32
33
34

35 In a review of the previous literature on the medical efficiency of CPGHs, we
36
37 found the following defects. 1. In China, county-level hospitals are divided into CPGHs,
38
39 traditional Chinese medical hospitals, and maternal and child health care hospitals.
40
41 Many studies do not subdivide the hospitals by type. Bates [23] found that different
42
43 types of hospitals have different resource allocation and output structures. 2. Most
44
45 studies have not considered the differences in production frontiers due to the different
46
47 natural, social and economic environments in different regions. Therefore, if the DEA
48
49 method is used to measure the medical efficiency of hospitals located in different
50
51 regions, it will not be able to capture the technical heterogeneities among them, and the
52
53 efficiency scores of the hospitals may not be accurate. 3. Ignoring the constraints of
54
55
56
57
58
59
60

1
2
3
4 medical quality, which is an unexpected output of DEA, will seriously affect hospital
5
6 efficiency. However, many studies have not considered the issue of unexpected output.
7
8
9 Based on these defects, this study makes the following improvements: 1. the medical
10
11 efficiency of 77 CPGHs, not including other types of county-level hospitals, is
12
13 evaluated; 2. the meta-frontier DEA model is used to evaluate the medical efficiency of
14
15 CPGHs in different regions and solve the problem of technical heterogeneity; and 3.
16
17 "adverse events" are selected as a medical quality indicator. Finally, the SBM-
18
19 undesirable DEA model is used to solve the problems related to unexpected outputs
20
21 categorized as "adverse events".
22
23
24
25
26

27 **Methods**

28 **Data Sources**

29
30
31
32 The data are mainly from the 2013-2019 Shanxi (a province with a population of
33
34 37 million in China) Statistical Yearbook and China Health Statistics Yearbook.
35
36 Overall, 77 CPGHs in Shanxi Province were selected. The data excluded other types of
37
38 hospitals, such as traditional Chinese medical hospitals, maternal and child health care
39
40 hospitals and other medical institutions, so they met the homogeneity requirement of
41
42 the DEA method.
43
44
45
46
47

48 **Meta-frontier and Group Frontier DEA Models**

49
50
51 The meta-frontier DEA model was first proposed by Battese [24]. The meta-
52
53 frontier refers to the potential technical level of all decision making units (DMUs), and
54
55 the group frontier refers to the actual technical level of each DMU. The difference
56
57 between them is the different technology sets to which they refer.
58
59
60

According to the meta-frontier DEA model of Battese [25], we took the unexpected output into account. In this case, the technology set (T^{meta}) includes all technically feasible input-output combinations:

$$T^{meta} = \left\{ \left(\begin{matrix} x \\ y \\ b \end{matrix} \right) : x \geq 0, y \geq 0, b \leq 0 \right\} \quad (1)$$

In the above formulation, x is the input vector, y is the expected output vector, and b is the unexpected output vector. That is, to obtain a certain output $P^{meta}(y, b)$, the input (x) must be satisfied under the given technological condition (T^{meta}). The production possibility set (meta-frontier) is as follows:

$$P^{meta}(x) = \{ (y, b) : (x, y, b) \in T^{meta} \} \quad (2)$$

Therefore, the technical efficiency function of the meta-frontier from the perspective of the output can be expressed as follows:

$$TE^{meta}(x, y, b) = \inf_{\lambda} \{ \lambda > 0 : \lambda (y, b) \in P^{meta}(y, b) \} \quad (3)$$

$$\vec{d}_0 = \left(\begin{matrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{matrix} \right) = \beta \left(\begin{matrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{matrix} \right) \quad (4)$$

where $\beta = (\beta_1, \beta_2, \beta_3)$ is the direction vector, β is the maximum possible expansion degree of a desirable output along the direction vector β , and the maximum possible reduction degree of an undesirable output along the direction vector is β .

According to the different levels of economic development, Shanxi Province is divided into three groups: Northern Shanxi, Central Shanxi and Southern Shanxi ($h=1, 2, 3$). The group technology set is:

$$T^h = \left\{ \left(\begin{matrix} x \\ y \\ b \end{matrix} \right) : x \geq 0, y \geq 0, b \leq 0; \sum_{i=1}^n \lambda_i = 1, \lambda_i \geq 0 \right\} \quad (4)$$

The production set is as follows:

$$P^h(x) = \{(x, y) : (x, y) \in P^h, h = 1, 2, 3\} \tag{5}$$

The group technical efficiency ($h=1,2,3$) can be expressed as:

$$TE^h(x, y) = \theta^h > 0 : (x, y) \in P^h(x, y), h = 1, 2, 3 \tag{6}$$

Meta-frontier technology is the envelope curve of the group frontier technology.

So: $P^h = \{P^1, P^2, P^3\}$.

Technology Gap Ratio (TGR)

The technology gap ratio [24] can be expressed by the meta-frontier and group technology efficiency functions:

$$TGR^h(x, y) = \frac{TE^h(x, y)}{TE^m(x, y)}, h = 1, 2, 3 \tag{7}$$

If the TGR is less than 1 or there are obvious differences between the mean values of TE^h and TE^m , it is necessary to divide the CPGHs into different groups. In contrast, if the TGR is close to 1 or there are no obvious differences between the mean values of TE^h and TE^m , there is no need to divide the CPGHs into different groups.

SBM-undesirable DEA Model

The SBM-undesirable DEA model [26] of unexpected output is used to construct the efficiency measurement model under the meta-frontier and group frontier conditions, and the formula is:

$$\rho^* = \min \frac{1 - \frac{1}{m} \sum_{h=1}^m \frac{s_h^-}{x_{h0}}}{1 + \frac{1}{s_1 + s_2} \left(\sum_{r=1}^{s_1} \frac{s_r^+}{y_{r0}} + \sum_{r=1}^{s_2} \frac{s_r^b}{b_{r0}} \right)} \tag{8}$$

$$s.t. \quad 0 = IZ + \theta$$

$$\theta_0 = \beta Z + \theta$$

$$0 = 4 \lambda$$

$$0, \quad 0, \quad 0$$

In the above formulation, X , Y and B represent the input and output vectors of different CPGHs each year. The meta-frontier represents 77 county regions, and the group frontier represents different groups in the 77 county regions; s^- , s^y and s^b are slack variables related to the input, expected output and unexpected output, respectively; r represents the r -th DMU; and r^0 represents the DMU to be assessed. The objective function decreases with α , β and γ where $0 < \alpha \leq 1$.

Because the data are from multiple years, homogeneity for each CPGH and statistical relations should be considered. Therefore, we adopted the global reference model proposed by Pastor and Lovell [27] to calculate the Malmquist index. This model can solve the comparability problem caused by considering different frontiers in efficiency evaluation.

Disease Complexity Adjustment for Discharged Patients

Since the disease complexity varies from hospital to hospital, it is unfair to simply input the approximate number of discharged patients into the input-output index. For example, hospitals with high technology levels are likely to treat patients with complicated conditions, and these hospitals will take more time to treat such a patient than to treat a patient with a mild illness. Hospitals with low technology levels can supply health services to patients with mild illness or light symptoms as a result of their limited technical capacities, and patients with severe illness may prefer directly seeking health services at high-level hospitals. Thus, 1000 patients in hospital-A will all have

difficult and complicated diseases, and those in hospital-B will have mild diseases.

However, when performing efficiency evaluation research, if a quantity of units 1000 is input without considering the complexity of the disease, it would be unfair to hospitals with high technical levels. Thus, the RCI index was used to adjust the numbers of discharged patients according to the average length of stay and bed utilization rate.

The specific adjustment methods were as follows:

$$P_i = P \times \left(\frac{ALoS_i}{ALoS_s} \right) \times \left(\frac{OCC_i}{OCC_s} \right) \quad (9)$$

In the above formula, $ALoS_i$ refers to the average length of stay in the i -th hospital, OCC_i refers to the bed utilization rate of the i -th hospital, and OCC_s refers to the average bed utilization rate of all evaluated hospitals. Therefore, the average length of stay will be adjusted upward for hospitals with higher bed utilization rates than the average. The actual number of discharged patients (P) was adjusted based on the RCI of each hospital, and finally, the number of discharged patients (EP) adjusted according to the RCI index was obtained. The formula is as follows:

$$EP = P \times \left(\frac{ALoS_i}{ALoS_s} \right) \times \left(\frac{OCC_i}{OCC_s} \right) \quad (10)$$

Patient and public involvement

No patient involved

Results and Analysis

Variable Selection

The variables were selected according to previous empirical research and the literature [7, 9, 12, 19-22]. Input variables usually include labor and capital [28]. In our study, the numbers of registered doctors and registered nurses were used to represent

the elements of human resources as input variables. Beds and equipment valued above 10,000 yuan were used as capital elements. The total visits, the number of discharged patients (EP) adjusted by the RCI and the number of operations were used as output variables. The number of adverse events was used to replace the unexpected output variable as a quality index. The descriptive statistics of the input-output indicators are shown in Table 1.

Table 1 Descriptive statistics

Input/output	Variable	Mean	Std. Dev.	Min	Max
Input variables	doctor	95.232	42.017	18	278
	nurse	117.985	71.658	9	390
	bed	250.217	125.748	80	790
	machine	226.736	145.973	35	831
Desirable output variables	treatment	95432.120	58710.450	16351	292534
	EP	9607.892	6610.737	756.4231	32707.7
	operations	1470.729	1189.186	81	7926
Undesirable output variables	adverse events	68.712	38.462	10	200

Note: The sample size in the model was 462

Test and Analysis of the Technology Gap Ratio (TGR)

Under a quality constraint, a mean value comparison test of the obtained technology gap ratio (TGR) was performed, as shown in Table 2. Assuming that the mean value was 1 and the significance level was 95%, the results showed that the

average TGR of each group was less than 1. After performing calculations, from 2013 to 2018, the mean value of the hospital TGR in the southern group was at the highest level, close to 1, reaching 0.93, followed by that of the central group of 0.91, and finally that of the northern group at only 0.63. This result indicated that the southern group was closest to the meta-frontier of technology in county-level public general hospitals, followed by the central group and the northern group. Obviously, both the overall TGR and the regional TGR values were significantly different from the assumed mean value of 1. Therefore, the heterogeneity of the division of public hospitals in Shanxi Province was very obvious, and this finding agreed the conditions of the DEA meta-frontier model; thus, the meta-frontier model could be suitably applied to analyze the results.

Table 2 Comparative test results of the mean value of the technology gap among county-level public general hospitals in northern, central and southern Shanxi Province from 2013 to 2018

Region	Mean TGR	t	P
North	0.62649	-17.2815	0.000
Central	0.907907	-8.9249	0.000
South	0.9328708	-6.9778	0.000
Entire	0.8494894	-15.6809	0.000

After calculating the efficiency of county-level general hospitals in Shanxi Province under meta-frontier and group frontier conditions, the temporal trends of the technology gaps in the north, central and southern regions under the quality constraint were further compared. The results are shown in Figure 1.

1
2
3
4 Figure 1 shows that the mean value of the TGR in the southern and central regions
5
6 of Shanxi Province was high, while that in the northern region was the lowest,
7
8 indicating that the central and southern regions provide better hospital management and
9
10 medical levels as a whole than did the northern region; additionally, they are closer to
11
12 the technological frontier. The mean value of the TGR in the central and southern
13
14 regions fluctuated at a high level and remained in a basically stable state, but the mean
15
16 value of the TGR in the northern region considerably changed. Except for a slight
17
18 increase in the mean TGR in 2016, other years experienced a downward trend, which
19
20 indicated that the medical level in the northern region decreased and that different
21
22 frontiers influenced the efficiency of county-level public general hospitals in different
23
24 regions of Shanxi Province.
25

31

32 **Time Series Analysis of the Technical Efficiency of Hospitals**

33
34
35 Figures 2A and B show the trend of the average comprehensive efficiency of
36
37 sample hospitals in Shanxi Province and in three major regions from 2013-2018 under
38
39 the meta-frontier and group frontier, respectively. Taking the meta-frontier in Figure
40
41 2A as a reference, the overall average medical service efficiency of county-level public
42
43 general hospitals was more than 0.6, and the medical service efficiency in each region
44
45 was relatively stable in each year; notably, the efficiency in the northern region
46
47 displayed a slow downward trend. Referring to Figure 2B, the overall average
48
49 efficiency for the group frontier was approximately 0.75, the southern region was
50
51 relatively stable, and the trends in the northern and central regions involved inverted U-
52
53 shaped curves in the early stage; however, all the regions experienced a significant
54
55
56
57
58
59
60

1
2
3
4 increase in 2018.
5

6
7 Figures 2C and D show the trend of the average comprehensive efficiency of the
8
9 sample hospitals in Shanxi Province and in three major regions under the meta-frontier
10
11 and the group frontier conditions, respectively, based on the quality constraints from
12
13 2013 to 2018. Taking the common frontier in Figure 2C as a reference, the overall
14
15 average medical service efficiency of county-level public general hospitals was
16
17 approximately 0.63, and the medical service efficiency trend in various regions
18
19 displayed an inverted U-shaped curve in each year; that is, it fluctuated and rose from
20
21 2013 to 2016 and then dropped rapidly after 2016. With reference to Figure 2D, the
22
23 overall average efficiency under the group frontier was approximately 0.75, and the
24
25 medical service efficiency trend in the northern region displayed a U-shaped curve that
26
27 fluctuated and decreased from 2013 to 2016 and then rose slowly after 2016. Moreover,
28
29 the efficiency trends in the central and southern regions were the same as those for the
30
31 meta-frontier.

38
39

40 **Analysis of the Differences in Hospital Technical Efficiency**

41
42
43 The distribution of the service efficiency of public general hospitals in Shanxi
44
45 Province is shown in Figure 3. Graph A shows the distribution of hospital efficiency
46
47 without quality constraints, and graph B presents the distribution of hospital efficiency
48
49 under quality constraints. In terms of location, the peak position of the distribution
50
51 curve in Figure 3B moves to the right compared with that in Figure 3A, indicating an
52
53 overall efficiency improvement. The kurtosis of the distribution curve for the central
54
55 and southern regions in Figure 3B is greater than that in Figure 3A, indicating that the
56
57
58
59
60

1
2
3
4 distribution of the efficiency was more concentrated in B. The northern distribution
5
6 curve in Figure 3B displays an obvious bimodal state, indicating that the efficiency
7
8 distribution was somewhat scattered. Therefore, quality constraints were very
9
10 important in the hospital efficiency evaluation. A lack of quality constraints would lead
11
12 to certain deviations in the evaluation results, and the results would not
13
14 comprehensively reflect the actual operation status of the medical system.
15
16
17

18
19 An analysis of the hospital efficiency distribution in Figure 3B was performed.
20
21 First, for the location, the distribution curves of the hospital efficiency density in the
22
23 northern, southern and central regions sequentially moved to the right. The distribution
24
25 curves of the southern and central regions were closely interlaced, indicating that the
26
27 hospital efficiency levels in the southern and central regions are similar and
28
29 significantly higher than the level in the northern region.
30
31
32

33
34
35 Second, the distribution curve of the efficiency density in northern hospitals peaks,
36
37 and the distribution curves of the efficiency density for the central and southern
38
39 hospitals displays broad kurtosis.
40
41
42

43 Finally, in terms of shape, the distribution curve of the efficiency density for
44
45 northern hospitals is bimodal, and those for the central and southern hospitals are
46
47 unimodal, suggesting that most hospitals in the central and southern regions have little
48
49 difference in medical level, while the medical level of northern hospitals is polarized;
50
51 this relation reflect the concept of “the strong get stronger, and the weak get weaker”
52
53 (Matthew's effect).
54
55

57 **Analysis of the Changes in Hospital Technical Efficiency Rankings**

58 To show the changes in efficiency among the sample hospitals before and after the
59
60

1
2
3
4 implementation of quality constraints, the comprehensive efficiency values of sample
5
6 hospitals under the two constraint conditions were ranked, and the changes in hospital
7
8 rankings were compared. The results are shown in Figure 4. In the northern region, the
9
10 ranking of hospital 17 increased the fastest, and the rankings of hospitals 6 and 13
11
12 decreased most obviously. In the central region, the ranking of hospital 24 increased
13
14 the fastest, and the ranking of hospital 29 decreased the most. In the southern region,
15
16 the ranking of hospital 71 increased the fastest, and the ranking of hospital 67 decreased
17
18 the most.
19
20
21
22
23

24
25 By analyzing the unexpected outputs of adverse events at hospitals, it was found
26
27 that the changes in efficiency rankings were related to the unexpected outputs of
28
29 adverse events; notably, the efficiency ranking increased when the unexpected output
30
31 level was low, and the ranking decreased when the unexpected output level was high.
32
33 For example, the average unexpected output of hospitals in the northern region was -
34
35 14.35, and that of hospital 17, with a medical quality higher than that of most hospitals,
36
37 was -3.38. However, the average unexpected outputs of hospitals 6 and 13 were -23.78
38
39 and -31.08, respectively, and the corresponding medical quality was lower than that of
40
41 other hospitals. Additionally, the average unexpected output values of hospitals in the
42
43 central and southern regions were -15.3 and -19.22, respectively, and the average
44
45 unexpected output values of hospitals 24 and 71 were only -3.09 and -3.49, respectively.
46
47 Moreover, the average unexpected output values of hospitals 29 and 67 were -23.99
48
49 and -57.25, respectively.
50
51
52
53
54
55
56
57

58 The Spearman rank correlation test was used to determine whether there was a
59
60

1
2
3
4 correlation between the hospital efficiency values under the two different constraints.
5
6 The significance level was 1%. The results showed that there was a positive correlation
7
8 between the efficiency values of sample hospitals under the two constraints. According
9
10 to the results, the three regions were different: the southern region had the highest
11
12 similarity, with a correlation coefficient of 0.9673, and the greatest difference was
13
14 observed in the northern region, with a correlation coefficient of 0.8452.
15
16
17
18

19 **Discussion**

20
21
22 This paper used the meta-frontier model and SBM-undesirable model to calculate
23
24 the efficiency of county-level public hospitals in Shanxi Province from 2013 to 2018.
25
26 Then, we evaluated the reform effect and resource utilization rate of county hospitals
27
28 and explored the influence of medical quality on hospital efficiency.
29
30
31

32
33 The results of this study showed that the efficiency level of county-level public
34
35 hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is
36
37 0.61 without quality constraints and 0.63 under quality constraints). In other studies,
38
39 the average efficiency of county hospitals in Chongqing was 0.83 [12], in Anhui
40
41 Province was 0.956 [19], and in China, as a mean value, was 0.7 [20], suggesting that
42
43 the efficiency of county-level hospitals in Shanxi Province is obviously low;
44
45 additionally, the utilization rate of existing resources is relatively low, and the
46
47 technology used is inefficient. To improve the efficiency level of county-level hospitals,
48
49 in addition to increasing investments to alleviate resource shortages, it is necessary to
50
51 improve the utilization efficiency of resources, such as improving hospital management,
52
53 rationally allocating human resources, and optimizing capital investments [29].
54
55
56
57
58
59
60

1
2
3
4 The results showed that the efficiency of county-level public hospitals in Shanxi
5
6 Province did not improve and even declined in some areas from 2013 to 2018 (Figure
7
8 2C). Although the reform of county-level hospitals was initiated in 2012, the effect was
9
10 not remarkable, as also noted by Jiang et al. [9]. Moreover, the study found that there
11
12 were regional differences in the efficiency of county-level public hospitals in Shanxi
13
14 Province. The efficiency level of county-level public hospitals in the central and
15
16 southern regions of Shanxi Province was high, while the efficiency level in the northern
17
18 region was comparatively low (Figure 2A and Figure 2C); these trends were also
19
20 reflected by the technology gap ratio distribution in each region (Figure 1), which
21
22 indicated that the county-level hospitals in the northern region were far from the
23
24 technological frontier. Therefore, increasing the resource inputs for hospitals in the
25
26 northern region of the province should be prioritized to improve their medical levels.
27
28 Additionally, the population and economic level in northern Shanxi Province are lower
29
30 than those in the central and southern regions [30]; thus, hospital efficiency may be
31
32 related to the economic environment and population.
33
34
35
36
37
38
39
40
41
42

43 This study also showed that quality constraints had an important impact on
44
45 hospital efficiency evaluation (Figures 3 and 4). Neglecting medical quality output
46
47 could lead to underestimates of the hospital efficiency level. This finding could
48
49 potentially be attributed to the fact that medical quality is often related to hospital
50
51 management and human resources [31]. With improvements in hospital management
52
53 and medical treatment ability, medical quality will also increase, as will the
54
55 corresponding hospital efficiency. Improving the quality of medical services is often
56
57
58
59
60

1
2
3
4 the goal of public hospitals [32], but many hospitals begin to expand blindly, resulting
5
6 in inefficiency [9,20,33]. Pang [34] et al. noted that improperly scaled expansion can
7
8 lead to technical efficiency in the short term but not in the long term. Therefore, to
9
10 improve the medical quality level, increasing the technological capacity and improving
11
12 management are steps.
13
14
15

16 17 **Conclusion**

18
19 This showed that after the implementation of county-level public hospital reform,
20
21 the efficiency level of county-level public hospitals in Shanxi Province did not improve
22
23 but remained low. Notably, the utilization rate of resources was low, and the reform
24
25 effect was not obvious. There are differences in the efficiency of county-level hospitals
26
27 in different regions, with the highest efficiency in the central region, the second-highest
28
29 level in the southern region and the lowest level in the northern region. To improve the
30
31 efficiency of hospitals, support to the northern region should be strengthened, hospital
32
33 management should be improved, and health human resources should be rationally
34
35 allocated.
36
37
38
39
40
41
42

43 The results also indicated that quality factors have a significant impact on hospital
44
45 efficiency evaluation. The keys to improving the level of medical quality are to improve
46
47 the proportion of technical personnel and the level of hospital management. The
48
49 expansion of county-level hospitals should consider the economic level and service area
50
51 in the region to avoid expansion and blind investment, potentially resulting in wasted
52
53 resources.

figure legend/caption

Figure 1 shows that the mean value of the TGR in the southern and central regions of Shanxi Province was high, while that in the northern region was the lowest, indicating that the central and southern regions provide better hospital management and medical levels as a whole than did the northern region; additionally, they are closer to the technological frontier.

Figures 2A and B show the trend of the average comprehensive efficiency of sample hospitals in Shanxi Province and in three major regions from 2013-2018 under the meta-frontier and group frontier, respectively.

The distribution of the service efficiency of public general hospitals in Shanxi Province is shown in Figure 3. Graph A shows the distribution of hospital efficiency without quality constraints, and graph B presents the distribution of hospital efficiency under quality constraints.

The results are shown in Figure 4. To show the changes in efficiency among the sample hospitals before and after the implementation of quality constraints, the comprehensive efficiency values of sample hospitals under the two constraint conditions were ranked, and the changes in hospital rankings were compared.

Abstract

Objectives: Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.

Methods: Based on the data from 77 county-level public general hospitals (CPGHs) in Shanxi Province, China, from 2013-2018, we applied the meta-frontier and SBM-undesirable DEA model to measure the CPGHs' medical service efficiency with or without medical quality constraints and evaluate the effects of the new medical reform to explore the utilization of health resources and look for ways to improve the CPGHs' medical service efficiency.

Results : The results of this study showed that the efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This

1
2
3
4 showed that ignoring medical quality constraints will result in lower efficiency and
5
6 lower health resource utilization for high medical quality hospitals. The medical service
7
8 efficiency of CPGHs differs greatly among different regions. Under the meta-frontier,
9
10 the hospitals in the central region had the highest efficiency (efficiency score 0.70),
11
12 followed by those in the south (efficiency score 0.63), and the hospitals in the north had
13
14 the lowest efficiency (efficiency score 0.54).
15
16
17
18

19 **Conclusion:** To improve CPGHs' medical service efficiency, the government should
20
21 increase investment in the northern region, and hospitals should improve the
22
23 management level and allocate human resources rationally.
24
25
26

31
32
33
34
35

36 **Strengths and limitations of this study**

- 37
38 ● We applied the Meta-frontier and SBM-undesirable DEA models to evaluate the
39
40 medical service efficiency, which effectively solved the problem that the efficiency
41
42 score of hospitals were not on the same production frontier.
43
44
- 45
46 ● Medical quality index was set as an output indicators in this study, which means that
47
48 the hospitals should not only focus on the number of patients, but also focus on the
49
50 medical quality.
51
52
- 53
54 ● Only 77 hospitals were chosen in one province, so the extrapolation of this study may
55
56 be limited.

Background

In March 2009, the Chinese government started a new medical reform. Since the implementation of the medical reform, China has made great achievements in expanding medical security services [1,2]. The government has vigorously developed primary medical and health services and strived to improve the fairness of the health service distribution [3]. However, the distribution of health resources in China is still unreasonable, and health resources are scarce [4]. High-quality medical resources are mainly concentrated in cities, leading to a significant medical quality gap between urban and rural hospitals [5-7]. Additionally, patients prefer to choose urban hospitals, which leads to the idleness of rural hospital resources [8]. Health resource waste and shortage issues have seriously restricted the service ability of medical and health institutions and led to low medical efficiency [9]. To solve these problems and improve the quality of medical services, the government has implemented a series of reforms in rural hospitals [1,10]. China's urban and rural medical system is mainly composed of urban tertiary hospitals, urban community hospitals, county-level hospitals and township health centers [11]. Among them, county-level public general hospitals (CPGHs) act as a link in China's urban and rural medical system, and they are the leaders of rural health institutions [12-14]. Their medical services have a wide range of radiation and cover a large population [9]. However, county-level hospitals also have problems such as shortages of human resources, low levels of medical services and uneven distributions of resources [14-16]. For example, Wu noted that the quality of human resources in primary hospitals is not high and the medical service level is poor

1
2
3
4 [17]. Jay found that the average resource levels of county-level hospitals in western
5
6 China were lower than those in other regions [18]. Therefore, it is very important to
7
8 improve the utilization rate of primary health resources and the medical efficiency of
9
10 county-level hospitals.
11
12

13
14 In recent years, many scholars have studied the medical efficiency of CPGHs in
15
16 China. Li measured the medical efficiency of 12 CPGHs in Anhui Province and found
17
18 that it has declined year by year; additionally, the medical reform effect of CPGHs was
19
20 not significant [19]. Wang analyzed the medical efficiency of 127 CPGHs in China and
21
22 found that the efficiency of CPGHs still has considerable room for improvement [20].
23
24 Jiang conducted a study of 1105 CPGHs in China and noted that although medical
25
26 reform has increased the scale of hospitals, it has not improved the medical efficiency
27
28 of CPGHs [9]. Other scholars' studies have also shown that the medical efficiency of
29
30 CPGHs has room for improvement [12,21,22]. Super SBM-undesirable DEA model
31
32 was used by (A. Monzeli) to measure the hospitals' emergency departments, which
33
34 indicated that the undesirable output can determine the hospitals' efficiency[23].
35
36
37
38
39
40
41
42

43 In a review of the previous literature on the medical efficiency of CPGHs, we
44
45 found the following defects. 1. In China, county-level hospitals are divided into CPGHs,
46
47 traditional Chinese medical hospitals, and maternal and child health care hospitals.
48
49 Many studies do not subdivide the hospitals by type. Bates [24] found that different
50
51 types of hospitals have different resource allocation and output structures. 2. Most
52
53 studies have not considered the differences in production frontiers due to the different
54
55 natural, social and economic environments in different regions. However, in other
56
57
58
59
60

1
2
3
4 industries, some relevant scholars have added relevant non-expected output indicators
5
6 for research when evaluating efficiency. In 2012, Majid Azadi [25] used SBM-
7
8 Undesirable DEA model to evaluate the efficiency of suppliers with adverse events, No.
9
10 Of personnel and Average time for serving customers (HR) were selected as input
11
12 indicators and Profit margin as expected output. No. Of Dissatisfied customers were
13
14 considered as Undesirable outputs, and the results showed that the SBM-Undesirable
15
16 DEA model could help decision makers choose suitable suppliers. In 2021, Tong
17
18 Guang Ji [26] evaluated agro-ecological efficiency in 136 developing countries using
19
20 SBM-Undesirable DEA model, Input indicators include Freshwater consumption,
21
22 Agricultural land area, Fertilizer consumption and Labor; expected output indicators
23
24 include Production and Forest area. Non-expected output indicators were selected as
25
26 Methane emissions and Nitrous oxide emissions. The results show that choosing
27
28 effective marginal tradeoff does not reduce the relative efficiency of dMU below the
29
30 effective boundary line. Thus, this approach enables decision makers to determine the
31
32 optimal marginal tradeoff point for optimal efficiency and to determine which output
33
34 factors require specialized brainstorming to design effective policies. Therefore, if the
35
36 DEA(Data Envelopment Analysis) method is used to measure the medical efficiency
37
38 of hospitals located in different regions, it will not be able to capture the technical
39
40 heterogeneities among them, and the efficiency scores of the hospitals may not be
41
42 accurate. 3. Ignoring the constraints of medical quality, which is an unexpected output
43
44 of DEA(Data Envelopment Analysis), will seriously affect hospital efficiency.
45
46 However, many studies have not considered the issue of unexpected output. Based on
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 these defects, this study makes the following improvements: 1. the medical efficiency
5
6 of 77 CPGHs, not including other types of county-level hospitals, is evaluated; 2. the
7
8 meta-frontier DEA(Data Envelopment Analysis) model is used to evaluate the medical
9
10 efficiency of CPGHs in different regions and solve the problem of technical
11
12 heterogeneity; and 3. "adverse events" are selected as a medical quality indicator.
13
14
15 Finally, the SBM-undesirable DEA model is used to solve the problems related to
16
17 unexpected outputs categorized as "adverse events".
18
19
20
21

22 **Methods**

23 **Data Sources**

24
25
26
27 The data are mainly from the 2013-2018 Shanxi (a province with a population of
28
29 37 million in China) Statistical Yearbook and China Health Statistics Yearbook.
30
31 Overall, 77 CPGHs in Shanxi Province were selected[27]. The data excluded other
32
33 types of hospitals, such as traditional Chinese medical hospitals, maternal and child
34
35 health care hospitals and other medical institutions, so they met the homogeneity
36
37 requirement of the DEA(Data Envelopment Analysis) method.
38
39
40
41

42 **Meta-frontier and Group Frontier DEA Models**

43
44
45 The meta-frontier DEA(Data Envelopment Analysis) model was first proposed by
46
47 Battese [28]. The meta-frontier refers to the potential technical level of all decision
48
49 making units (DMUs), and the group frontier refers to the actual technical level of each
50
51 DMU. The difference between them is the different technology sets to which they refer.
52
53
54

55
56 According to the meta-frontier DEA(Data Envelopment Analysis) model of
57
58 Battese [29], we took the unexpected output into account. In this case, the technology
59
60

set (T^{meta}) includes all technically feasible input-output combinations:

$$T^{meta} = \{(x,y,b):x \geq 0,y \geq 0,b \geq 0; \text{ } x \text{ can produce } (y,b)\} \quad (1)$$

In the above formulation, x is the input vector, y is the expected output vector, and b is the unexpected output vector. That is, to obtain a certain output $P^{meta}(y, b)$, the input (x) must be satisfied under the given technological condition (T^{meta}). The production possibility set (meta-frontier) is as follows:

$$P^{meta}(x) = \{(y,b) : (x,y,b) \in T^{meta}\} \quad (2)$$

Therefore, the technical efficiency function of the meta-frontier from the perspective of the output can be expressed as follows:

$$TE^{meta}(x,y,b) = \inf_{\beta} \{\beta > 0 : (y/\beta) \in P^{meta}(y,b)\} \quad (3)$$

According to the different levels of economic development, Shanxi Province is divided into three groups: Northern Shanxi, Central Shanxi and Southern Shanxi ($h=1, 2, 3$). The group technology set is:

$$T^h = \{(x_h,y_h,b_h):x_h \geq 0,y_h \geq 0,b_h \geq 0;x_h \rightarrow (y_h,b_h)\}, h = 1,2,3 \quad (4)$$

The production set is as follows:

$$P^h(x_h) = \{(y_h,b_h):(x_h,y_h,b_h) \in T^h\}, h = 1,2,3 \quad (5)$$

The group technical efficiency ($h=1,2,3$) can be expressed as:

$$TE^h(x_h,y_h,b_h) = \inf_{\beta} \{\beta > 0:(y_h/\beta) \in P^h(y_h,b_h)\}, h = 1,2,3 \quad (6)$$

Meta-frontier technology is the envelope curve of the group frontier technology.

So: $T^m = \{T^1 \cup T^2 \cup T^3\}$.

Technology Gap Ratio (TGR)

The technology gap ratio [28] can be expressed by the meta-frontier and group

technology efficiency functions(The results are shown in Figure 1.):

$$TGR^h(x_h, y_h, b_h) = \frac{TE^{meta}(x, y, b)}{TE^h(x_h, y_h, b_h)}, h = 1, 2, 3 \quad (7)$$

Fig 1 Schematic diagram of common frontier and group frontier

Take R Hospital located in Group3 as an example, then

$$TE^{meta}(R) = \frac{OC}{OA} \cdot TE^h(R) = \frac{OC}{OB} \cdot TGR^h(R) = \frac{TE^{meta}}{TE^h} = \frac{OC/OA}{OC/OB} = \frac{OB}{OA} \quad (8)$$

If the TGR is less than 1 or there are obvious differences between the mean values of TE^{meta} and TE^h , it is necessary to divide the CPGHs into different groups. In contrast, if the TGR is close to 1 or there are no obvious differences between the mean values of TE^{meta} and TE^h , there is no need to divide the CPGHs into different groups.

SBM-undesirable DEA Model

The SBM-undesirable (Slacks-based Measurement-undesirable) DEA model [30] of unexpected output is used to construct the efficiency measurement model under the meta-frontier and group frontier conditions, and the formula is:

$$\rho^* = \min \frac{1 - \frac{1}{m} \sum_{i=1}^m \frac{s_{i0}^-}{x_{i0}}}{1 + \frac{1}{s} \left(\sum_{r=1}^{s_1} \frac{s_r^g}{y_{r0}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{y_{r0}^b} \right)}$$

Subject to

$$x_0 = X\lambda + S^-$$

$$y^g = Y\lambda - S^g$$

$$y_0^b = Y\lambda + S^b$$

$$L \leq e\lambda \leq U$$

$$S^-, S^g, S^b, \lambda \geq 0. \quad (9)$$

In the above formulation, X , Y and B represent the input and output vectors of

1
2
3
4 different CPGHs each year. The meta-frontier represents 77 county regions, and the
5
6 group frontier represents different groups in the 77 county regions; s^- , s^y and s^b are slack
7
8 variables related to the input, expected output and unexpected output, respectively; r
9
10 represents the r -th DMU; and r^0 represents the DMU to be assessed. The objective
11
12 function ρ^* decreases with $s_h^-(\forall h)$, $s_r^y(\forall r)$ and $s_r^b(\forall r)$, where $0 < \rho^* \leq 1$.
13
14

15
16
17 Because the data are from multiple years, homogeneity for each CPGH and
18
19 statistical relations should be considered. Therefore, we adopted the global reference
20
21 model proposed by Pastor and Lovell [31] to calculate the Malmquist index. This model
22
23 can solve the comparability problem caused by considering different frontiers in
24
25 efficiency evaluation.
26
27
28

29 30 **Disease Complexity Adjustment for Discharged Patients**

31
32 Since the disease complexity varies from hospital to hospital, it is unfair to simply
33
34 input the approximate number of discharged patients into the input-output index. For
35
36 example, hospitals with high technology levels are likely to treat patients with
37
38 complicated conditions, and these hospitals will take more time to treat such a patient
39
40 than to treat a patient with a mild illness. Hospitals with low technology levels can
41
42 supply health services to patients with mild illness or light symptoms as a result of their
43
44 limited technical capacities, and patients with severe illness may prefer directly seeking
45
46 health services at high-level hospitals. Thus, 1000 patients in hospital-A will all have
47
48 difficult and complicated diseases, and those in hospital-B will have mild diseases.
49
50 However, when performing efficiency evaluation research, if a quantity of units 1000
51
52 is input without considering the complexity of the disease, it would be unfair to
53
54
55
56
57
58
59
60

1
2
3
4 hospitals with high technical levels. However, the RCI index can be used to adjust the
5
6 numbers of discharged patients according to the average length of stay and bed
7
8 utilization rate[32]. Since the poor quality of the patient records in county-level hospitals, we
9
10 select RCI index, which provides a reference for efficiency evaluation in underdeveloped areas.
11
12

13
14 The specific adjustment methods were as follows:
15

$$16 \quad RCI_i = ALoS_i * (OCC_i/OCC_s) \quad (10)$$

17
18 In the above formula, $ALoS_i$ refers to the average length of stay in the i -th hospital,
19
20 OCC_i refers to the bed utilization rate of the i -th hospital, and OCC_s refers to the average
21
22 bed utilization rate of all evaluated hospitals. Therefore, the average length of stay will
23
24 be adjusted upward for hospitals with higher bed utilization rates than the average. The
25
26 actual number of discharged patients (P) was adjusted based on the RCI of each hospital,
27
28 and finally, the number of discharged patients (EP) adjusted according to the RCI index
29
30 was obtained. The formula is as follows:
31
32
33
34
35
36

$$37 \quad EP = P * (RCI_i/RCI_s) \quad (11)$$

38 39 40 **Patient and public involvement**

41
42 No patient involved
43

44 45 **Results and Analysis**

46 47 **Variable Selection**

48
49 The variables were selected according to previous empirical research and the
50
51 literature [7, 9, 12, 19-22]. Input variables usually include labor and capital [33]. In our
52
53 study, the numbers of registered doctors and registered nurses were used to represent
54
55 the elements of human resources as input variables. Beds and equipment valued above
56
57
58
59
60

10,000 yuan were used as capital elements. The total visits, the number of discharged patients (EP) adjusted by the RCI and the number of operations were used as output variables. The number of adverse events was used to replace the unexpected output variable as a quality index[34]. The descriptive statistics of the input-output indicators are shown in Table 1.

Table 1 Descriptive statistics

Input/output	Variable	Mean	Std. Dev.	Min	Max
Input variables	doctor	95.232	42.017	18	278
	nurse	117.985	71.658	9	390
	bed	250.217	125.748	80	790
	machine	226.736	145.973	35	831
Desirable output variables	treatment	95432.120	58710.450	16351	292534
	EP	9607.892	6610.737	756.4231	32707.7
	operations	1470.729	1189.186	81	7926
Undesirable output variables	adverse events	68.712	38.462	10	200

Note: The sample size in the model was 462

Test and Analysis of the Technology Gap Ratio (TGR)

Under a quality constraint, a mean value comparison test of the obtained technology gap ratio (TGR) was performed, as shown in Table 2. Assuming that the mean value was 1 and the significance level was 95%, the results showed that the average TGR of each group was less than 1. After performing calculations, from 2013

to 2018, the mean value of the hospital TGR in the southern group was at the highest level, close to 1, reaching 0.93, followed by that of the central group of 0.91, and finally that of the northern group at only 0.63. This result indicated that the southern group was closest to the meta-frontier of technology in county-level public general hospitals, followed by the central group and the northern group. Obviously, both the overall TGR and the regional TGR values were significantly different from the assumed mean value of 1. Therefore, the heterogeneity of the division of public hospitals in Shanxi Province was very obvious, and this finding agreed the conditions of the DEA(Data Envelopment Analysis) meta-frontier model; thus, the meta-frontier model could be suitably applied to analyze the results.

Table 2 Comparative test results of the mean value of the technology gap among county-level public general hospitals in northern, central and southern Shanxi Province from 2013 to 2018

Region	Mean TGR	t	P
North	0.62649	-17.2815	0.000
Central	0.907907	-8.9249	0.000
South	0.9328708	-6.9778	0.000
Entire	0.8494894	-15.6809	0.000

After calculating the efficiency of county-level general hospitals in Shanxi Province under meta-frontier and group frontier conditions, the temporal trends of the technology gaps in the north, central and southern regions under the quality constraint were further compared. The results are shown in Figure 2.

1
2
3
4 Figure 2 shows that the mean value of the TGR in the southern and central regions
5
6 of Shanxi Province was high, while that in the northern region was the lowest,
7
8 indicating that the central and southern regions provide better hospital management and
9
10 medical levels as a whole than did the northern region; additionally, they are closer to
11
12 the technological frontier. The mean value of the TGR in the central and southern
13
14 regions fluctuated at a high level and remained in a basically stable state, but the mean
15
16 value of the TGR in the northern region considerably changed. Except for a slight
17
18 increase in the mean TGR in 2016, other years experienced a downward trend, which
19
20 indicated that the medical level in the northern region decreased and that different
21
22 frontiers influenced the efficiency of county-level public general hospitals in different
23
24 regions of Shanxi Province.
25
26
27
28
29
30
31

32 **Time Series Analysis of the Technical Efficiency of Hospitals**

34
35 Figures 3A and B show the trend of the average comprehensive efficiency of
36
37 sample hospitals in Shanxi Province and in three major regions from 2013-2018 under
38
39 the meta-frontier and group frontier, respectively. Taking the meta-frontier in Figure
40
41 3A as a reference, the overall average medical service efficiency of county-level public
42
43 general hospitals was more than 0.6, and the medical service efficiency in each region
44
45 was relatively stable in each year; notably, the efficiency in the northern region
46
47 displayed a slow downward trend. Referring to Figure 3B, the overall average
48
49 efficiency for the group frontier was approximately 0.75, the southern region was
50
51 relatively stable, and the trends in the northern and central regions involved inverted U-
52
53 shaped curves in the early stage; however, all the regions experienced a significant
54
55
56
57
58
59
60

1
2
3
4 increase in 2018.
5

6
7 Figures 3C and D show the trend of the average comprehensive efficiency of the
8
9 sample hospitals in Shanxi Province and in three major regions under the meta-frontier
10
11 and the group frontier conditions, respectively, based on the quality constraints from
12
13 2013 to 2018. Taking the common frontier in Figure 3C as a reference, the overall
14
15 average medical service efficiency of county-level public general hospitals was
16
17 approximately 0.63, and the medical service efficiency trend in various regions
18
19 displayed an inverted U-shaped curve in each year; that is, it fluctuated and rose from
20
21 2013 to 2016 and then dropped rapidly after 2016. With reference to Figure 3D, the
22
23 overall average efficiency under the group frontier was approximately 0.75, and the
24
25 medical service efficiency trend in the northern region displayed a U-shaped curve that
26
27 fluctuated and decreased from 2013 to 2016 and then rose slowly after 2016. Moreover,
28
29 the efficiency trends in the central and southern regions were the same as those for the
30
31 meta-frontier.
32
33
34
35
36
37
38
39

40 **Analysis of the Differences in Hospital Technical Efficiency**

41
42
43 The distribution of the service efficiency of public general hospitals in Shanxi
44
45 Province is shown in Figure 4. Graph A shows the distribution of hospital efficiency
46
47 without quality constraints, and graph B presents the distribution of hospital efficiency
48
49 under quality constraints. In terms of location, the peak position of the distribution
50
51 curve in Figure 4B moves to the right compared with that in Figure 4A, indicating an
52
53 overall efficiency improvement. The kurtosis of the distribution curve for the central
54
55 and southern regions in Figure 4B is greater than that in Figure 4A, indicating that the
56
57
58
59
60

1
2
3
4 distribution of the efficiency was more concentrated in B. The northern distribution
5
6 curve in Figure 4B displays an obvious bimodal state, indicating that the efficiency
7
8 distribution was somewhat scattered. Therefore, quality constraints were very
9
10 important in the hospital efficiency evaluation. A lack of quality constraints would lead
11
12 to certain deviations in the evaluation results, and the results would not
13
14 comprehensively reflect the actual operation status of the medical system.
15
16
17

18
19 An analysis of the hospital efficiency distribution in Figure 4B was performed.
20
21 First, for the location, the distribution curves of the hospital efficiency density in the
22
23 northern, southern and central regions sequentially moved to the right. The distribution
24
25 curves of the southern and central regions were closely interlaced, indicating that the
26
27 hospital efficiency levels in the southern and central regions are similar and
28
29 significantly higher than the level in the northern region.
30
31
32
33

34
35 Second, the distribution curve of the efficiency density in northern hospitals peaks,
36
37 and the distribution curves of the efficiency density for the central and southern
38
39 hospitals displays broad kurtosis.
40
41
42

43 Finally, in terms of shape, the distribution curve of the efficiency density for
44
45 northern hospitals is bimodal, and those for the central and southern hospitals are
46
47 unimodal, suggesting that most hospitals in the central and southern regions have little
48
49 difference in medical level, while the medical level of northern hospitals is polarized;
50
51 this relation reflect the concept of “the strong get stronger, and the weak get weaker”
52
53 (Matthew's effect).
54
55
56

57 **Analysis of the Changes in Hospital Technical Efficiency Rankings**

58 To show the changes in efficiency among the sample hospitals before and after the
59
60

1
2
3
4 implementation of quality constraints, the comprehensive efficiency values of sample
5
6 hospitals under the two constraint conditions were ranked, and the changes in hospital
7
8 rankings were compared. The results are shown in Figure 5. In the northern region, the
9
10 ranking of hospital 17 increased the fastest, and the rankings of hospitals 6 and 13
11
12 decreased most obviously. In the central region, the ranking of hospital 24 increased
13
14 the fastest, and the ranking of hospital 29 decreased the most. In the southern region,
15
16 the ranking of hospital 71 increased the fastest, and the ranking of hospital 67 decreased
17
18 the most.
19
20
21
22
23

24
25 By analyzing the unexpected outputs of adverse events at hospitals, it was found
26
27 that the changes in efficiency rankings were related to the unexpected outputs of
28
29 adverse events; notably, the efficiency ranking increased when the unexpected output
30
31 level was low, and the ranking decreased when the unexpected output level was high.
32
33 For example, the average unexpected output of hospitals in the northern region was -
34
35 14.35, and that of hospital 17, with a medical quality higher than that of most hospitals,
36
37 was -3.38. However, the average unexpected outputs of hospitals 6 and 13 were -23.78
38
39 and -31.08, respectively, and the corresponding medical quality was lower than that of
40
41 other hospitals. Additionally, the average unexpected output values of hospitals in the
42
43 central and southern regions were -15.3 and -19.22, respectively, and the average
44
45 unexpected output values of hospitals 24 and 71 were only -3.09 and -3.49, respectively.
46
47 Moreover, the average unexpected output values of hospitals 29 and 67 were -23.99
48
49 and -57.25, respectively.
50
51
52
53
54
55
56

57
58 The Spearman rank correlation test was used to determine whether there was a
59
60

1
2
3
4 correlation between the hospital efficiency values under the two different constraints.
5
6 The significance level was 1%. The results showed that there was a positive correlation
7
8 between the efficiency values of sample hospitals under the two constraints. According
9
10 to the results, the three regions were different: the southern region had the highest
11
12 similarity, with a correlation coefficient of 0.9673, and the greatest difference was
13
14 observed in the northern region, with a correlation coefficient of 0.8452.
15
16
17
18

19 **Discussion**

20
21
22 This paper used the meta-frontier model and SBM-undesirable(Slacks-based
23
24 Measurement-undesirable) model to calculate the efficiency of county-level public
25
26 hospitals in Shanxi Province from 2013 to 2018. Then, we evaluated the reform effect
27
28 and resource utilization rate of county hospitals and explored the influence of medical
29
30 quality on hospital efficiency.
31
32
33
34

35
36 The results of this study showed that the efficiency level of county-level public
37
38 hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is
39
40 0.61 without quality constraints and 0.63 under quality constraints). In other studies,
41
42 the average efficiency of county hospitals in Chongqing was 0.83 [12], in Anhui
43
44 Province was 0.956 [19], and in China, as a mean value, was 0.7 [20], suggesting that
45
46 the efficiency of county-level hospitals in Shanxi Province is obviously low;
47
48 additionally, the utilization rate of existing resources is relatively low, and the
49
50 technology used is inefficient. To improve the efficiency level of county-level hospitals,
51
52 in addition to increasing investments to alleviate resource shortages, it is necessary to
53
54 improve the utilization efficiency of resources, such as improving hospital management,
55
56
57
58
59
60

rationally allocating human resources, and optimizing capital investments [35].

The results showed that the efficiency of county-level public hospitals in Shanxi Province did not improve and even declined in some areas from 2013 to 2018 (Figure 2C). Although the reform of county-level hospitals was initiated in 2012, the effect was not remarkable, as also noted by Jiang et al. [9]. Moreover, the study found that there were regional differences in the efficiency of county-level public hospitals in Shanxi Province. The efficiency level of county-level public hospitals in the central and southern regions of Shanxi Province was high, while the efficiency level in the northern region was comparatively low (Figure 2A and Figure 2C); these trends were also reflected by the technology gap ratio distribution in each region (Figure 1), which indicated that the county-level hospitals in the northern region were far from the technological frontier. Therefore, increasing the resource inputs for hospitals in the northern region of the province should be prioritized to improve their medical levels. Additionally, the population and economic level in northern Shanxi Province are lower than those in the central and southern regions [36]; thus, hospital efficiency may be related to the economic environment and population.

This study also showed that quality constraints had an important impact on hospital efficiency evaluation (Figures 3 and 4). Neglecting medical quality output could lead to underestimates of the hospital efficiency level. This finding could potentially be attributed to the fact that medical quality is often related to hospital management and human resources [37]. With improvements in hospital management and medical treatment ability, medical quality will also increase, as will the

1
2
3
4 corresponding hospital efficiency. Improving the quality of medical services is often
5
6 the goal of public hospitals [38], but many hospitals begin to expand blindly, resulting
7
8 in inefficiency [20,39,40]. Pang [41] et al. noted that improperly scaled expansion can
9
10 lead to technical efficiency in the short term but not in the long term. Therefore, to
11
12 improve the medical quality level, increasing the technological capacity and improving
13
14 management are steps.
15
16
17

18 19 **Conclusion**

20
21
22 This showed that after the implementation of county-level public hospital reform,
23
24 the efficiency level of county-level public hospitals in Shanxi Province did not improve
25
26 but remained low. Notably, the utilization rate of resources was low, and the reform
27
28 effect was not obvious. There are differences in the efficiency of county-level hospitals
29
30 in different regions, with the highest efficiency in the central region, the second-highest
31
32 level in the southern region and the lowest level in the northern region. To improve the
33
34 efficiency of hospitals, support to the northern region should be strengthened, hospital
35
36 management should be improved, and health human resources should be rationally
37
38 allocated.
39
40
41
42
43
44

45
46 The results also indicated that quality factors have a significant impact on hospital
47
48 efficiency evaluation. The keys to improving the level of medical quality are to improve
49
50 the proportion of technical personnel and the level of hospital management. The
51
52 expansion of county-level hospitals should consider the economic level and service area
53
54 in the region to avoid expansion and blind investment, potentially resulting in wasted
55
56 resources.

25 **Abstract**

26
27 **Objectives:** Since the new medical reform in 2009, county-level hospitals in China
28
29 have achieved rapid development, but health resource waste and shortage issues still
30
31 exist.
32
33

34
35 **Methods:** Based on the data from 77 county-level public general hospitals (CPGHs) in
36
37 Shanxi Province, China, from 2013-2018, we applied the meta-frontier and SBM-
38
39 undesirable (Slacks-based Measurement-undesirable) DEA(Data Envelopment
40
41 Analysis) model to measure the CPGHs' medical service efficiency with or without
42
43 medical quality constraints and evaluate the effects of the new medical reform to
44
45 explore the utilization of health resources and look for ways to improve the CPGHs'
46
47 medical service efficiency. Moreover, we analyze the factors affecting public hospital
48
49 efficiency based on the FRM model.
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 **Results** : The results of this study showed that the efficiency level of county-level
5
6 public hospitals in Shanxi Province is relatively low overall (the mean value of
7
8 efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This
9
10 showed that ignoring medical quality constraints will result in lower efficiency and
11
12 lower health resource utilization for high medical quality hospitals. The medical service
13
14 efficiency of CPGHs differs greatly among different regions. Under the meta-frontier,
15
16 the hospitals in the central region had the highest efficiency (efficiency score 0.70),
17
18 followed by those in the south (efficiency score 0.63), and the hospitals in the north had
19
20 the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the
21
22 service efficiency of county public hospitals are the average length of hospital stay, per
23
24 capita disposable income and financial subsidy income.
25
26
27
28
29
30

31
32 **Conclusion:** To improve CPGHs' medical service efficiency, the government should
33
34 increase investment in the northern region, and hospitals should improve the
35
36 management level and allocate human resources rationally.
37
38
39

40 **Keywords:** County-level Hospital Efficiency, Medical quality, Meta-frontier DEA
41
42 Model, SBM-Undesirable DEA Model.

49 **Strengths and limitations of this study**

- 50
51
52
53
54
55
56
57
58
59
60
- The Meta-frontier and SBM-undesirable DEA models effectively solved the problem that the efficiency score of hospitals was not on the same production frontier.
 - Medical quality index was set as an output indicator in this study, which means that the hospitals should not only focus on the number of patients, but also focus on the

1
2
3
4 medical quality.

- 5
6
7 • Only 77 hospitals were chosen in one province, so the extrapolation of this study may
8
9 be limited.

10 11 12 13 14 15 **Background**

16
17 In March 2009, the Chinese government started a new medical reform. Since the
18
19 implementation of the medical reform, China has made great achievements in
20
21 expanding medical security services [1,2]. The government has vigorously developed
22
23 primary medical and health services and strived to improve the fairness of the health
24
25 service distribution [3]. However, the distribution of health resources in China is still
26
27 unreasonable, and health resources are scarce [4]. High-quality medical resources are
28
29 mainly concentrated in cities, leading to a significant medical quality gap between
30
31 urban and rural hospitals [5-7]. Additionally, patients prefer to choose urban hospitals,
32
33 which leads to the idleness of rural hospital resources [8]. Health resource waste and
34
35 shortage issues have seriously restricted the service ability of medical and health
36
37 institutions and led to low medical efficiency [9]. To solve these problems and improve
38
39 the quality of medical services, the government has implemented a series of reforms in
40
41 rural hospitals [1,10]. China's urban and rural medical system is mainly composed of
42
43 urban tertiary hospitals, urban community hospitals, county-level hospitals and
44
45 township health centers [11]. Among them, county-level public general hospitals
46
47 (CPGHs) act as a link between China's urban and rural medical systems, and they are
48
49 the leaders of rural health institutions [12-14]. Their medical services have a wide range
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 of radiation and cover a large population [9]. However, county-level hospitals also have
5
6 problems such as shortages of human resources, low levels of medical services and
7
8 uneven distributions of resources [14-16]. For example, Wu noted that the quality of
9
10 human resources in primary hospitals is not high and the medical service level is poor
11
12 [17]. Jay found that the average resource levels of county-level hospitals in western
13
14 China were lower than those in other regions [18]. Therefore, it is very important to
15
16 improve the utilization rate of primary health resources and the medical efficiency of
17
18 county-level hospitals.
19
20
21
22
23

24
25 In recent years, many scholars have studied the medical efficiency of CPGHs in
26
27 China. Li measured the medical efficiency of 12 CPGHs in Anhui Province and found
28
29 that it has declined year by year; additionally, the medical reform effect of CPGHs was
30
31 not significant [19]. Wang analyzed the medical efficiency of 127 CPGHs in China and
32
33 found that the efficiency of CPGHs still has considerable room for improvement [20].
34
35 Jiang conducted a study of 1105 CPGHs in China and noted that although medical
36
37 reform has increased the scale of hospitals, it has not improved the medical efficiency
38
39 of CPGHs [9]. Other scholars' studies have also shown that the medical efficiency of
40
41 CPGHs has room for improvement [12,21,22]. Super SBM-undesirable (Slacks-based
42
43 Measurement-undesirable) DEA(Data Envelopment Analysis) model was used by A.
44
45 Monzeli to measure the hospital's emergency departments, which indicated that the
46
47 undesirable output can determine the hospitals' efficiency [23].
48
49
50
51
52
53
54
55

56 In a review of the previous literature on the medical efficiency of CPGHs, we
57
58 found the following defects. 1. In China, county-level hospitals are divided into CPGHs,
59
60

1
2
3
4 traditional Chinese medical hospitals, and maternal and child health care hospitals.
5
6 However, most studies do not subdivide the hospitals by type. Bates [24] found that
7
8 different types of hospitals have different resource allocation and output structures. 2.
9
10 Most studies have not considered the differences in production frontiers due to the
11
12 different natural, social and economic environments in different regions. However, in
13
14 other industries, some relevant scholars have added relevant non-expected output
15
16 indicators for research when evaluating efficiency. In 2012, Majid Azadi [25] used the
17
18 SBM-Undesirable DEA model to evaluate the efficiency of suppliers with adverse
19
20 events, No. Of personnel and Average time for serving customers (HR) were selected
21
22 as input indicators and Profit margin as expected output. No. Of Dissatisfied customers
23
24 were considered as Undesirable outputs, and the results showed that the SBM-
25
26 Undesirable DEA model could help decision makers choose suitable suppliers. In 2021,
27
28 Tong Guang Ji [26] evaluated agro-ecological efficiency in 136 developing countries
29
30 using the SBM-Undesirable DEA model, Input indicators include Freshwater
31
32 consumption, Agricultural land area, and Fertilizer consumption and Labor; expected
33
34 output indicators include Production and Forest area. Non-expected output indicators
35
36 were selected as Methane emissions and Nitrous oxide emissions. The results show that
37
38 choosing an effective marginal tradeoff does not reduce the relative efficiency of dMU
39
40 below the effective boundary line. Thus, this approach enables decision makers to
41
42 determine the optimal marginal tradeoff point for optimal efficiency and to determine
43
44 which output factors require specialized brainstorming to design effective policies.
45
46 Therefore, if the DEA (Data Envelopment Analysis) method is used to measure the
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 medical efficiency of hospitals located in different regions, it will not be able to capture
5
6 the technical heterogeneities among them, and the efficiency scores of the hospitals
7
8 may not be accurate. 3. Ignoring the constraints of medical quality, which is an
9
10 unexpected output of DEA, will seriously affect hospital efficiency. However, many
11
12 studies have not considered the issue of unexpected output.
13
14
15

16
17 Based on these defects, this study makes the following improvements: 1. the
18
19 medical efficiency of 77 CPGHs, not including other types of county-level hospitals, is
20
21 evaluated; 2. the meta-frontier DEA model is used to evaluate the medical efficiency of
22
23 CPGHs in different regions and solve the problem of technical heterogeneity; and 3.
24
25 "adverse events" are selected as a medical quality indicator. Finally, the SBM-
26
27 undesirable DEA model is used to solve the problems related to unexpected outputs
28
29 categorized as "adverse events".
30
31
32
33

34 35 **Methods**

36 37 **Data Sources**

38
39 The data are mainly from the 2013-2018 Shanxi (a province with a population of
40
41 37 million in China) Statistical Yearbook and China Health Statistics Yearbook.
42
43 Overall, 77 CPGHs in Shanxi Province were selected [27]. The data excluded other
44
45 types of hospitals, such as traditional Chinese medical hospitals, maternal and child
46
47 health care hospitals and other medical institutions, so they met the homogeneity
48
49 requirement of the DEA(Data Envelopment Analysis) method.
50
51
52
53
54

55 56 **Meta-frontier and Group Frontier DEA Models**

57
58 The meta-frontier DEA model was first proposed by Battese [28]. The meta-
59
60

frontier refers to the potential technical level of all decision making units (DMUs), and the group frontier refers to the actual technical level of each DMU. The difference between them is the different technology sets to which they refer.

According to the meta-frontier DEA model of Battese [29], we took the unexpected output into account. In this case, the technology set (T^{meta}) includes all technically feasible input-output combinations:

$$T^{meta} = \{(x,y,b): x \geq 0, y \geq 0, b \geq 0; x \text{ can produce } (y,b)\} \quad (1)$$

In the above formulation, x is the input vector, y is the expected output vector, and b is the unexpected output vector. That is, to obtain a certain output $P^{meta}(y, b)$, the input (x) must be satisfied under the given technological condition (T^{meta}). The production possibility set (meta-frontier) is as follows:

$$P^{meta}(x) = \{(y,b) : (x,y,b) \in T^{meta}\} \quad (2)$$

Therefore, the technical efficiency function of the meta-frontier from the perspective of the output can be expressed as follows:

$$TE^{meta}(x,y,b) = \inf_{\beta} \{\beta > 0 : (y/\beta) \in P^{meta}(y,b)\} \quad (3)$$

According to the different levels of economic development, Shanxi Province is divided into three groups: Northern Shanxi, Central Shanxi and Southern Shanxi ($h=1, 2, 3$). The group technology set is:

$$T^h = \{(x_h, y_h, b_h): x_h \geq 0, y_h \geq 0, b_h \geq 0; x_h \rightarrow (y_h, b_h)\}, h = 1, 2, 3 \quad (4)$$

The production set is as follows:

$$P^h(x_h) = \{(y_h, b_h): (x_h, y_h, b_h) \in T^h\}, h = 1, 2, 3 \quad (5)$$

The group technical efficiency ($h=1, 2, 3$) can be expressed as:

$$TE^h(x_h, y_h, b_h) = \inf_{\beta} \{\beta > 0 : (y_h/\beta) \in P^h(y_h, b_h)\}, h = 1, 2, 3 \quad (6)$$

Meta-frontier technology is the envelope curve of the group frontier technology.

So: $T^m = \{T^1 \cup T^2 \cup T^3\}$.

Technology Gap Ratio (TGR)

The technology gap ratio [28] can be expressed by the meta-frontier and group technology efficiency functions (The results are shown in Figure 1):

$$TGR^h(x_h, y_h, b_h) = \frac{TE^{meta}(x, y, b)}{TE^h(x_h, y_h, b_h)}, h = 1, 2, 3 \quad (7)$$

Fig 1 Schematic diagram of common frontier and group frontier

Take R Hospital located in Group3 as an example, then

$$TE^{meta}(R) = \frac{OC}{OA} \cdot TE^h(R) = \frac{OC}{OB} \cdot TGR^h(R) = \frac{TE^{meta}}{TE^h} = \frac{OC/OA}{OC/OB} = \frac{OB}{OA} \quad (8)$$

If the TGR is less than 1 or there are obvious differences between the mean values of TE^{meta} and TE^h , it is necessary to divide the CPGHs into different groups. In contrast, if the TGR is close to 1 or there are no obvious differences between the mean values of TE^{meta} and TE^h , there is no need to divide the CPGHs into different groups.

SBM-undesirable DEA Model

The SBM-undesirable (Slacks-based Measurement-undesirable) DEA model [30] of unexpected output is used to construct the efficiency measurement model under the meta-frontier and group frontier conditions, and the formula is:

$$\rho^* = \min \frac{1 - \frac{1}{m} \sum_{i=1}^m \frac{s_{i0}^-}{x_{i0}}}{1 + \frac{1}{s} \left(\sum_{r=1}^{s_1} \frac{s_r^+}{y_{r0}} + \sum_{r=1}^{s_2} \frac{s_r^+}{y_{r0}^b} \right)}$$

Subject to

$$x_0 = X\lambda + S^-$$

$$\begin{aligned}
 y^g &= Y\lambda - S^g \\
 y_0^b &= Y\lambda + S^b \\
 L &\leq e\lambda \leq U \\
 S^-, S^g, S^b, \lambda &\geq 0.
 \end{aligned} \tag{9}$$

In the above formulation, X , Y and B represent the input and output vectors of different CPGHs each year. The meta-frontier represents 77 county regions, and the group frontier represents different groups in the 77 county regions; s^- , s^g and s^b are slack variables related to the input, expected output and unexpected output, respectively; r represents the r -th DMU; and r^0 represents the DMU to be assessed. The objective function ρ^* decreases with $s_h^-(\forall h)$, $s_r^g(\forall r)$ and $s_r^b(\forall r)$, where $0 < \rho^* \leq 1$.

Because the data are from multiple years, homogeneity for each CPGH and statistical relations should be considered. Therefore, we adopted the global reference model proposed by Pastor and Lovell [31] to calculate the Malmquist index. This model can solve the comparability problem caused by considering different frontiers in efficiency evaluation.

Disease Complexity Adjustment for Discharged Patients

Since the disease complexity varies from hospital to hospital, it is unfair to simply input the approximate number of discharged patients into the input-output index. For example, hospitals with high technology levels are likely to treat patients with complicated conditions, and these hospitals will take more time to treat such a patient than to treat a patient with a mild illness. Hospitals with low technology levels can supply health services to patients with mild illness or light symptoms as a result of their

1
2
3
4 limited technical capacities, and patients with severe illness may prefer directly seeking
5
6 health services at high-level hospitals. Thus, 1000 patients in hospital-A will all have
7
8 difficult and complicated diseases, and those in hospital-B will have mild diseases.
9
10 However, when performing efficiency evaluation research, if a quantity of units 1000
11
12 is input without considering the complexity of the disease, it would be unfair to
13
14 hospitals with high technical levels. However, the RCI index can be used to adjust the
15
16 numbers of discharged patients according to the average length of stay and bed
17
18 utilization rate [32]. Given the poor quality of the patient records in county-level hospitals,
19
20 we select the RCI index, which provides a reference for efficiency evaluation in
21
22 underdeveloped areas. The specific adjustment methods were as follows:
23
24
25
26
27
28

$$RCI_i = ALoS_i * (OCC_i/OCC_s) \quad (10)$$

29
30
31 In the above formula, $ALoS_i$ refers to the average length of stay in the i -th hospital,
32
33 OCC_i refers to the bed utilization rate of the i -th hospital, and OCC_s refers to the average
34
35 bed utilization rate of all evaluated hospitals. Therefore, the average length of stay will
36
37 be adjusted upward for hospitals with higher bed utilization rates than the average. The
38
39 actual number of discharged patients (P) was adjusted based on the RCI of each hospital,
40
41 and finally, the number of discharged patients (EP) adjusted according to the RCI index
42
43 was obtained. The formula is as follows:
44
45
46
47
48
49

$$EP = P * (RCI_i/RCI_s) \quad (11)$$

50 51 52 **FRM (Fractional Response Model)**

53
54
55 The regression equation is:

$$EFFICIENCY_{it} = \beta_0 + \beta_1 \ln INCOME_{it} + \beta_2 \ln POPULATION_{it} + \beta_3$$

$$\ln SUBIDY_{it} + \beta_4 \ln DAY_{it} + \beta_5 BEDRATIO_{it} + \beta_6 STAFFRATIO_{it} + \varepsilon_{it} \quad (12)$$

where $EFFICIENCY_{it}$ represents the service efficiency of the hospital i in year t , β_0 is a constant term. $INCOME_{it}$ and $POPULATION_{it}$ represent the per capita disposable income and residents population of the district (county) where the hospital i is located in year t , respectively; $SUBIDY_{it}$, DAY_{it} , $BEDRATIO_{it}$ and $STAFFRATIO_{it}$ represent the subsidy, average length of hospital stay, hospital bed utilization rate and the proportion of health technicians, respectively. ε_{it} is the error term. This paper uses Stata16.0 software for data processing and regression.

To examine the factors that influence the service efficiency of public hospitals, this paper uses the panel Tobit model with right-side restriction for regression. One of the defects of the Tobit model is that it has a strong dependence on distribution and is sensitive to the problem of heteroscedasticity. If the error term does not follow the normal distribution or has a heteroscedasticity issue, the estimation will be inconsistent [33]. In addition, there are some problems in using the Tobit model to analyze the factors of hospital efficiency [34]. In fact, the hospital efficiency in this paper is a natural consequence of the way DEA is defined, and the hospital efficiency measured according to the Non-oriented EBM model is inherently between 0 and 1, which is not because of the Tobit model that set the efficiency greater than 1 to the value of 1.

Papke and Wooldridge [35] proposed the Fractional Response Model (FRM) in 1996, which overcomes many of the limitations of linear and nonlinear econometric models when studying bounded data. Ramalho et.al. [36] further developed the FRM model. The FRM model is a nonlinear model using the Quasi-Maximum Likelihood

1
2
3
4 Estimation (QMLE). Compared with the Tobit model, the QMLE is asymptotically
5
6 efficient and consistent because the FRM model does not require distributional or
7
8 heteroskedasticity assumptions on the DEA score [37]. In addition, the advantages of
9
10 the FRM model are that it allows a nonlinear relationship between hospital efficiency
11
12 and its determinants, allows error terms to have autocorrelation, and does not allow the
13
14 efficiency score to fall outside 0-1, which are in line with the research content of this
15
16 paper. To this end, this paper uses the Fractional Response Model (FRM) for robustness
17
18 testing. The specification is:
19
20
21
22

$$23 \quad E(y_i|x_i) = G(x_i\beta) \quad (13)$$

24
25 where the subscript i represents hospital, x_i are the factors, and β is the
26
27 parameter to be estimated. $G(\eta) = \exp(\eta)/[1 + \exp(\eta)]$ represents a probability
28
29 distribution function in the form of Logit whose domain is all real numbers and whose
30
31 range is (0,1).
32
33
34
35
36

37 Referring to Papke & Wooldridge [35], the log-likelihood equation can be
38
39 estimated by Quasi maximum likelihood estimation (QMLE):
40
41

$$42 \quad l_i(\beta) = y_i \ln [G(x_i\beta)] + (1-y_i) \ln [1-G(x_i\beta)] \quad (14)$$

43
44 Finally, maximize Equation (15) to obtain the value of β in Equation (13).
45
46

$$47 \quad \max_{\beta} \sum_{i=1}^{269} l_i(\beta) \quad (15)$$

48 **Patient and public involvement**

49 No patient involved
50

51 **Results and Analysis**

52 **Variable Selection**

The variables were selected according to previous empirical research and the literature [7, 9, 12, 19-22]. Input variables usually include labor and capital [38]. In our study, the numbers of registered doctors and registered nurses were used to represent the elements of human resources as input variables. Beds and equipment valued above 10,000 yuan were used as capital elements. The total visits, the number of discharged patients (EP) adjusted by the RCI and the number of operations were used as output variables. The number of adverse events was used to replace the unexpected output variable as a quality index [39]. The descriptive statistics of the input-output indicators are shown in Table 1.

Table 1. Descriptive statistics

Input/output	Variable	Mean	Std. Dev.	Min	Max
Input variables	doctor	95.232	42.017	18	278
	nurse	117.985	71.658	9	390
	bed	250.217	125.748	80	790
	machine	226.736	145.973	35	831
Desirable output variables	treatment	95432.120	58710.450	16351	292534
	EP	9607.892	6610.737	756.4231	32707.7
	operations	1470.729	1189.186	81	7926
Undesirable output variables	adverse events	68.712	38.462	10	200

Note: The sample size in the model was 462

The variables for FRM, the dependent variable is the service efficiency of public

hospitals. As for the independent variables, according to the existing literature and the consideration of data availability and sample size, the following six types of factors affecting the service efficiency of county-level public hospitals were selected for analysis, including (1) External factors: per capita disposable income of residents (county-level economic factor), number of usual residents (county-level population factor); (2) Internal factors: financial subsidy income (hospital-level financial factor), the proportion of health technicians (human resource factor), hospital bed utilization rate (equipment implementation factor), average length of hospital stay (service delivery factor). The summary of variables for FRM is shown in Table 2.

Table 2. Summary of variables for FRM

Variable name	Variable	Definition
Hospital service efficiency	<i>EFFICIEN</i> <i>CY</i>	Service efficiency of each county-level public hospital calculated according to the Non-oriented EBM model
Per capita disposable income (yuan)	<i>INCOME</i>	Per capita disposable income of usual residents
Resident population (person)	<i>POPULAT</i> <i>ION</i>	Population of usual residents
Financial subsidy income (ten thousand yuan)	<i>SUBSIDY</i>	Financial subsidy received by hospitals
Average length of hospital stay	<i>DAY</i>	$\frac{\text{Number of days that beds are occupied by dischargers}}{\text{Number of people discharged}}$
Utilization rate of hospital bed	<i>BEDRATI</i> <i>O</i>	$\frac{\text{Number of days that beds are actually occupied}}{\text{Number of days that beds are available}}$
Proportion of health technicians	<i>STAFFRAT</i> <i>IO</i>	$\frac{\text{Number of Inspection Technician and Imaging Technician}}{\text{Number of employees}}$

Test and Analysis of the Technology Gap Ratio (TGR)

Under a quality constraint, a mean value comparison test of the obtained technology gap ratio (TGR) was performed, as shown in Table 3. Assuming that the

mean value was 1 and the significance level was 95%, the results showed that the average TGR of each group was less than 1. After performing calculations, from 2013 to 2018, the mean value of the hospital TGR in the southern group was at the highest level, close to 1, reaching 0.93, followed by that of the central group of 0.91, and finally that of the northern group at only 0.63. This result indicated that the southern group was closest to the meta-frontier of technology in county-level public general hospitals, followed by the central group and the northern group. Obviously, both the overall TGR and the regional TGR values were significantly different from the assumed mean value of 1. Therefore, the heterogeneity of the division of public hospitals in Shanxi Province was very obvious, and this finding agreed on the conditions of the DEA meta-frontier model; thus, the meta-frontier model could be suitably applied to analyze the results.

Table 3. Comparative test results of the mean value of the technology gap among county-level public general hospitals in northern, central and southern Shanxi Province from 2013 to 2018

Region	Mean TGR	t	P
North	0.62649	-17.2815	0.000
Central	0.907907	-8.9249	0.000
South	0.9328708	-6.9778	0.000
Entire	0.8494894	-15.6809	0.000

After calculating the efficiency of county-level general hospitals in Shanxi Province under meta-frontier and group frontier conditions, the temporal trends of the technology gaps in the north, central and southern regions under the quality constraint

1
2
3
4 were further compared. The results are shown in Figure 2.
5

6
7 Figure 2 shows that the mean value of the TGR in the southern and central regions
8
9 of Shanxi Province was high, while that in the northern region was the lowest,
10
11 indicating that the central and southern regions provide better hospital management and
12
13 medical levels as a whole than did the northern region; additionally, they are closer to
14
15 the technological frontier. The mean value of the TGR in the central and southern
16
17 regions fluctuated at a high level and remained in a basically stable state, but the mean
18
19 value of the TGR in the northern region considerably changed. Except for a slight
20
21 increase in the mean TGR in 2016, other years experienced a downward trend, which
22
23 indicated that the medical level in the northern region decreased and that different
24
25 frontiers influenced the efficiency of county-level public general hospitals in different
26
27 regions of Shanxi Province.
28
29
30
31
32
33

34 35 **Time Series Analysis of the Technical Efficiency of Hospitals** 36

37
38 Figures 3A and B show the trend of the average comprehensive efficiency of
39
40 sample hospitals in Shanxi Province and in three major regions from 2013-2018 under
41
42 the meta-frontier and group frontier, respectively. Taking the meta-frontier in Figure
43
44 3A as a reference, the overall average medical service efficiency of county-level public
45
46 general hospitals was more than 0.6, and the medical service efficiency in each region
47
48 was relatively stable each year; notably, the efficiency in the northern region displayed
49
50 a slow downward trend. Referring to Figure 3B, the overall average efficiency for the
51
52 group frontier was approximately 0.75, the southern region was relatively stable, and
53
54 the trends in the northern and central regions involved inverted U-shaped curves in the
55
56
57
58
59
60

1
2
3
4 early stage; however, all the regions experienced a significant increase in 2018.
5

6
7 Figures 3C and D show the trend of the average comprehensive efficiency of the
8
9 sample hospitals in Shanxi Province and in three major regions under the meta-frontier
10
11 and the group frontier conditions, respectively, based on the quality constraints from
12
13 2013 to 2018. Taking the common frontier in Figure 3C as a reference, the overall
14
15 average medical service efficiency of county-level public general hospitals was
16
17 approximately 0.63, and the medical service efficiency trend in various regions
18
19 displayed an inverted U-shaped curve in each year; that is, it fluctuated and rose from
20
21 2013 to 2016 and then dropped rapidly after 2016. Regarding Figure 3D, the overall
22
23 average efficiency under the group frontier was approximately 0.75, and the medical
24
25 service efficiency trend in the northern region displayed a U-shaped curve that
26
27 fluctuated and decreased from 2013 to 2016 and then rose slowly after 2016. Moreover,
28
29 the efficiency trends in the central and southern regions were the same as those for the
30
31 meta-frontier.
32

34
35
36
37
38
39

40 **Analysis of the Differences in Hospital Technical Efficiency**

41
42
43 The distribution of the service efficiency of public general hospitals in Shanxi
44
45 Province is shown in Figure 4. Graph A shows the distribution of hospital efficiency
46
47 without quality constraints, and graph B presents the distribution of hospital efficiency
48
49 under quality constraints. In terms of location, the peak position of the distribution
50
51 curve in Figure 4B moves to the right compared with that in Figure 4A, indicating an
52
53 overall efficiency improvement. The kurtosis of the distribution curve for the central
54
55 and southern regions in Figure 4B is greater than that in Figure 4A, indicating that the
56
57
58
59
60

1
2
3
4 distribution of the efficiency was more concentrated in B. The northern distribution
5
6 curve in Figure 4B displays an obvious bimodal state, indicating that the efficiency
7
8 distribution was somewhat scattered. Therefore, quality constraints were very
9
10 important in the hospital efficiency evaluation. A lack of quality constraints would lead
11
12 to certain deviations in the evaluation results, and the results would not
13
14 comprehensively reflect the actual operation status of the medical system.
15
16
17
18

19 An analysis of the hospital efficiency distribution in Figure 4B was performed.
20
21 First, for the location, the distribution curves of the hospital efficiency density in the
22
23 northern, southern and central regions sequentially moved to the right. The distribution
24
25 curves of the southern and central regions were closely interlaced, indicating that the
26
27 hospital efficiency levels in the southern and central regions are similar and
28
29 significantly higher than the level in the northern region.
30
31
32
33

34
35 Second, the distribution curve of the efficiency density in northern hospitals peaks,
36
37 and the distribution curves of the efficiency density for the central and southern
38
39 hospitals displays broad kurtosis.
40
41
42

43 Finally, in terms of shape, the distribution curve of the efficiency density for
44
45 northern hospitals is bimodal, and those for the central and southern hospitals are
46
47 unimodal, suggesting that most hospitals in the central and southern regions have little
48
49 difference in medical level, while the medical level of northern hospitals is polarized;
50
51 this relation reflects the concept of “the strong get stronger, and the weak get weaker”
52
53 (Matthew's effect).
54
55
56

57 **Analysis of the Changes in Hospital Technical Efficiency Rankings**

58 To show the changes in efficiency among the sample hospitals before and after the
59
60

1
2
3
4 implementation of quality constraints, the comprehensive efficiency values of sample
5
6 hospitals under the two constraint conditions were ranked, and the changes in hospital
7
8 rankings were compared. The results are shown in Figure 5. In the northern region, the
9
10 ranking of hospital 17 increased the fastest, and the rankings of hospitals 6 and 13
11
12 decreased most obviously. In the central region, the ranking of hospital 24 increased
13
14 the fastest, and the ranking of hospital 29 decreased the most. In the southern region,
15
16 the ranking of hospital 71 increased the fastest, and the ranking of hospital 67 decreased
17
18 the most.
19
20
21
22
23

24
25 By analyzing the unexpected outputs of adverse events at hospitals, it was found
26
27 that the changes in efficiency rankings were related to the unexpected outputs of
28
29 adverse events; notably, the efficiency ranking increased when the unexpected output
30
31 level was low, and the ranking decreased when the unexpected output level was high.
32
33 For example, the average unexpected output of hospitals in the northern region was -
34
35 14.35, and that of hospital 17, with a medical quality higher than that of most hospitals,
36
37 was -3.38. However, the average unexpected outputs of hospitals 6 and 13 were -23.78
38
39 and -31.08, respectively, and the corresponding medical quality was lower than that of
40
41 other hospitals. Additionally, the average unexpected output values of hospitals in the
42
43 central and southern regions were -15.3 and -19.22, respectively, and the average
44
45 unexpected output values of hospitals 24 and 71 were only -3.09 and -3.49, respectively.
46
47 Moreover, the average unexpected output values of hospitals 29 and 67 were -23.99
48
49 and -57.25, respectively.
50
51
52
53
54
55
56
57

58 The Spearman rank correlation test was used to determine whether there was a
59
60

correlation between the hospital efficiency values under the two different constraints. The significance level was 1%. The results showed that there was a positive correlation between the efficiency values of sample hospitals under the two constraints. According to the results, the three regions were different: the southern region had the highest similarity, with a correlation coefficient of 0.9673, and the greatest difference was observed in the northern region, with a correlation coefficient of 0.8452.

Analysis of factors affecting public hospital efficiency

The result on factors affecting public hospital efficiency based on the FRM model is shown in Table 4.

Table 4. Regression result of the FRM model

	(1)FRM-Logit	(2)FRM-Logit
<i>Constant</i>	-63.1201 (57.5153)	174.6323** (69.2530)
<i>ln INCOME</i>	23.9425*** (8.0147)	57.9482*** (9.1432)
<i>ln POPULATION</i>	11.7407** (4.8335)	18.0447*** (4.9030)
<i>ln SUBSIDY</i>	18.2966*** (2.1988)	13.6022*** (2.1659)
<i>ln DAY</i>	-53.1396*** (8.9505)	-53.4437*** (8.9724)
<i>BEDRATIO</i>	1.8526*** (0.1080)	1.8717*** (0.1104)
<i>STAFFRATIO</i>	4.3761*** (1.1724)	3.9982*** (1.1333)
Wald test	570.78(0.0000)	758.54(0.0000)
Time fixed effect	No	Yes
County fixed effect	No	Yes
Hospital category effect	No	Yes
Observations	1430	1430

Note: The data in parentheses after each coefficient is the standard deviation. To facilitate comparison with the Tobit model, both coefficients and standard deviation are multiplied by 100. In the Wald test, the values on the left side of the parentheses are the values of χ^2 distribution, and the values in the parentheses are the corresponding P values. ***, **, and * represent 1%, 5%, and 10% significance level, respectively.

We can find that the coefficient of per capita income is positive and significant,

1
2
3
4 that is, the improvement of residents' per capita disposable income can improve the
5
6 service efficiency of county public hospitals; Population factor negatively impacts
7
8 public hospital efficiency when the fixed effects are not controlled. After controlling
9
10 for the fixed effects, the coefficient is significantly positive, that is, the resident
11
12 population in the county where the hospital is located is positively correlated with the
13
14 service efficiency of county public hospitals; The effect of financial subsidy income on
15
16 the service efficiency of county public hospitals is significantly positive; The
17
18 coefficient for the average length of hospital stay is the largest and significantly
19
20 negative; And the proportion of health technicians has a significant positive impact on
21
22 the service efficiency of public hospitals.
23

25
26
27
28
29
30

31 **Discussion**

32
33
34 This paper used the meta-frontier model and SBM-undesirable (Slacks-based
35
36 Measurement-undesirable) model to calculate the efficiency of county-level public
37
38 hospitals in Shanxi Province from 2013 to 2018. Then, we evaluated the reform effect
39
40 and resource utilization rate of county hospitals and explored the influence of medical
41
42 quality on hospital efficiency. Moreover, we analyze the factors affecting public
43
44 hospital efficiency based on the FRM model.
45
46
47
48

49
50 The results of this study showed that the efficiency level of county-level public
51
52 hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is
53
54 0.61 without quality constraints and 0.63 under quality constraints). In other studies,
55
56 the average efficiency of county hospitals in Chongqing was 0.83 [12], in Anhui
57
58 Province was 0.956 [19], and in China, as a mean value, was 0.7 [20], suggesting that
59
60

1
2
3
4 the efficiency of county-level hospitals in Shanxi Province is obviously low;
5
6 additionally, the utilization rate of existing resources is relatively low, and the
7
8 technology used is inefficient. To improve the efficiency level of county-level hospitals,
9
10 in addition to increasing investments to alleviate resource shortages, it is necessary to
11
12 improve the utilization efficiency of resources, such as improving hospital management,
13
14 rationally allocating human resources, and optimizing capital investments [40].
15
16
17
18

19
20 The results showed that the efficiency of county-level public hospitals in Shanxi
21
22 Province did not improve and even declined in some areas from 2013 to 2018 (Figure
23
24 2C). Although the reform of county-level hospitals was initiated in 2012, the effect was
25
26 not remarkable, as also noted by Jiang et al. [9]. Moreover, the study found that there
27
28 were regional differences in the efficiency of county-level public hospitals in Shanxi
29
30 Province. The efficiency level of county-level public hospitals in the central and
31
32 southern regions of Shanxi Province was high, while the efficiency level in the northern
33
34 region was comparatively low (Figure 2A and Figure 2C); these trends were also
35
36 reflected by the technology gap ratio distribution in each region (Figure 1), which
37
38 indicated that the county-level hospitals in the northern region were far from the
39
40 technological frontier. Therefore, increasing the resource inputs for hospitals in the
41
42 northern region of the province should be prioritized to improve their medical levels.
43
44 Additionally, the population and economic level in northern Shanxi Province are lower
45
46 than those in the central and southern regions [41]; thus, hospital efficiency may be
47
48 related to the economic environment and population.
49
50
51
52
53
54
55
56

57
58 This study also showed that quality constraints had an important impact on
59
60

1
2
3
4 hospital efficiency evaluation (Figures 3 and 4). Neglecting medical quality output
5
6 could lead to underestimates of the hospital efficiency level. This finding could
7
8 potentially be attributed to the fact that medical quality is often related to hospital
9
10 management and human resources [42]. With improvements in hospital management
11
12 and medical treatment ability, medical quality will also increase, as will the
13
14 corresponding hospital efficiency. Improving the quality of medical services is often
15
16 the goal of public hospitals [43], but many hospitals begin to expand blindly, resulting
17
18 in inefficiency [20,44,45]. Pang [46] et al. noted that improperly scaled expansion can
19
20 lead to technical efficiency in the short term but not in the long term. Therefore, to
21
22 improve the medical quality level, increasing the technological capacity and improving
23
24 management are steps.
25
26
27
28
29
30
31

32 For the factors that influence public hospital efficiency, firstly, when the per capita
33
34 disposable income of residents is high, people may pay more attention to their health,
35
36 and have more requirements for the service and technical level of the hospital.
37
38 Accordingly, health services will be used more rationally. Secondly, the more resident
39
40 population in the region, the greater the intensity of the demand for medical services,
41
42 and the hospital will continuously improve its medical service to meet the demand, thus
43
44 making the hospital service more efficient. The reason for the low level of significance
45
46 level is that: on the one hand, the resident population is the macro-level data, which has
47
48 little impact on the efficiency of the micro-level hospital; on the other hand, the mobility
49
50 of people seeking medical treatment is high, so the population of the area where the
51
52 hospital is located has limited effect on the efficiency of the local hospital. Thirdly, if
53
54
55
56
57
58
59
60

1
2
3
4 the government increases the financial investment in the hospital, it will help the
5
6 hospital to introduce high-tech equipment and improve the hospital's infrastructure
7
8
9 construction capacity, etc. Thus it will prompt the hospital to realize the rational
10
11 allocation of resources under the guidance of the government's policy of increasing the
12
13 corresponding investment. As a result, the hospital achieves more efficient health
14
15 service, improving the efficiency of hospital services. Fourthly, the average length of
16
17 hospital stay is an important factor affecting the service efficiency of public hospitals,
18
19 and a longer length of hospital stay will reduce the service efficiency level of the
20
21 hospital. This may be because a longer length of hospital stay means hospitals are not
22
23 treating patients in a timely manner or have to deal with more severe cases, making
24
25 hospital services less efficient. Fifthly, the bed utilization rate reflects the vacant beds
26
27 in the hospital. The higher the hospital bed utilization rate, the more patients can be
28
29 provided with hospital-stay services at the same time, thereby increasing the hospital-
30
31 stay service output and improving the hospital's service efficiency. Sixthly, for the
32
33 positive impact of the proportion of health technicians, the reason may be that the higher
34
35 the proportion of health technicians, the higher the level of medical service, and the
36
37 further improvement of the service efficiency of the hospital.
38
39
40
41
42
43
44
45
46
47

48 **Limitations**

49
50 This study evaluated the efficiency of county public hospitals in Shanxi Province
51
52 and explored the influence of scale on hospital efficiency. It provided a reference for
53
54 the government and hospitals to reasonably control bed size. However, the study has
55
56 Only 77 hospitals were chosen in one province, so the extrapolation of this study may
57
58
59
60

1
2
3
4 be limited.
5

6 **Conclusion** 7

8
9 This showed that after the implementation of county-level public hospital reform,
10 the efficiency level of county-level public hospitals in Shanxi Province did not improve
11 but remained low. Notably, the utilization rate of resources was low, and the reform
12 effect was not obvious. There are differences in the efficiency of county-level hospitals
13 in different regions, with the highest efficiency in the central region, the second-highest
14 level in the southern region and the lowest level in the northern region. To improve the
15 efficiency of hospitals, support to the northern region should be strengthened, hospital
16 management should be improved, and health human resources should be rationally
17 allocated.
18
19
20
21
22
23
24
25
26
27
28
29
30
31

32 The results also indicated that quality factors have a significant impact on hospital
33 efficiency evaluation. The keys to improving the level of medical quality are to improve
34 the proportion of technical personnel and the level of hospital management. The
35 expansion of county-level hospitals should consider the economic level and service area
36 in the region to avoid expansion and blind investment, potentially resulting in wasted
37 resources.
38
39
40
41
42
43
44
45
46
47

48 According to the FRM regression results, it is concluded that the factors that have
49 larger impacts on the service efficiency of county public hospitals are the average length
50 of hospital stay, per capita disposable income and financial subsidy income. Shortening
51 the average hospital stay can improve hospital efficiency. In areas with higher per capita
52 disposable income of residents, the service efficiency of county-level public hospitals
53
54
55
56
57
58
59
60

1
2
3
4 is higher. And the increase in subsidy has a positive effect on the improvement of
5
6 hospital service efficiency. In addition, the county population, bed utilization rate and
7
8 the proportion of health technicians also have significant impacts on hospital service
9
10 efficiency. The higher the population, the higher the hospital efficiency. Increasing the
11
12 bed utilization rate and the proportion of health technicians will also promote hospital
13
14 service efficiency. However, only 77 hospitals in one province were selected for this
15
16 study, so the extrapolation from this study may be limited.

Fig.5 Changes in the efficiency ranking of county-level public general hospitals in Shanxi Province before and after the implementation of quality constraints

STROBE checklist

	Recommendation	page
Title and abstract	<p>Study of the Medical Service Efficiency of County-Level Public General Hospitals Based on Medical Quality Constraints: a cross-sectional study</p> <p>Objectives: Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.</p> <p>Methods: Based on the data from 77 county-level public general hospitals (CPGHs) in Shanxi Province, China, from 2013-2018, we applied the meta-frontier and SBM-undesirable (Slacks-based Measurement-undesirable) DEA(Data Envelopment Analysis) model to measure the CPGHs' medical service efficiency with or without medical quality constraints and evaluate the effects of the new medical reform to explore the utilization of health resources and look for ways to improve the CPGHs' medical service efficiency. Moreover, we analyze the factors affecting public hospital efficiency based on the FRM model.</p> <p>Results : The results of this study showed that the efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This showed that ignoring medical quality constraints will result in lower efficiency and lower health resource utilization for high medical quality hospitals. The medical service efficiency of CPGHs differs greatly among different regions. Under the meta-frontier, the hospitals in the central region had the highest efficiency (efficiency score 0.70), followed by those in the south (efficiency score 0.63), and the hospitals in the north had the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income.</p> <p>Conclusion: To improve CPGHs' medical service efficiency, the government should increase investment in the northern region, and hospitals should improve the management level and allocate human resources rationally.</p>	1-2
Introduction		
Background/rationale	<p>Background: 1. In China, county-level hospitals are divided into CPGHs, traditional Chinese medical hospitals, and maternal and child health care hospitals. However, most studies do not subdivide the hospitals by type, and different types of hospitals have different resource allocation and output structures.</p> <p>2. In China, most studies have not considered the differences in production frontiers due to the different natural, social and economic environments in different regions. However, in other industries, some relevant scholars have added relevant non-expected output indicators for research when evaluating efficiency.</p> <p>3. Ignoring the constraints of medical quality, which is an unexpected output of DEA, will seriously affect hospital efficiency. However, In China, many studies have not considered the issue of unexpected output.</p> <p>Rationale: 1. This study used the meta-frontier DEA model to evaluate the medical efficiency of CPGHs in different regions and it can solve the problem</p>	4-6

	of technical heterogeneity; 2. This study selected "adverse events" as a medical quality indicator. And used the SBM-undesirable DEA model is to solve the problems related to unexpected outputs categorized as "adverse events".	
Objectives	Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.	1
Methods		
Study design	a cross-sectional study	1
Setting	The data are mainly from the 2013-2018 Shanxi (a province with a population of 37 million in China) Statistical Yearbook and China Health Statistics Yearbook. Overall, 77 CPGHs in Shanxi Province were selected	6
Variables	Input variables: doctor, nurse, bed and machine; Desirable output variables: treatment, EP and operations; Undesirable output variables: adverse events	13
Data sources/ measurement	The data are mainly from the 2013-2018 Shanxi (a province with a population of 37 million in China) Statistical Yearbook and China Health Statistics Yearbook. Overall, 77 CPGHs in Shanxi Province were selected. The data excluded other types of hospitals, such as traditional Chinese medical hospitals, maternal and child health care hospitals and other medical institutions.	6
Results		
Main results	The efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This showed that ignoring medical quality constraints will result in lower efficiency and lower health resource utilization for high medical quality hospitals. The medical service efficiency of CPGHs differs greatly among different regions. Under the meta-frontier, the hospitals in the central region had the highest efficiency (efficiency score 0.70), followed by those in the south (efficiency score 0.63), and the hospitals in the north had the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income.	1-2
Discussion		
Key results	According to the FRM regression results, it is concluded that the factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income. Shortening the average hospital stay can improve hospital efficiency. In areas with higher per capita disposable income of residents, the service efficiency of county-level public hospitals is higher. And the increase in subsidy has a positive effect on the improvement of hospital service efficiency. In addition, the county population, bed utilization rate and the proportion of health technicians also have significant impacts on hospital service efficiency. The higher the population, the higher the hospital efficiency. Increasing the bed utilization rate and the proportion of health technicians will also promote hospital service efficiency.	25-26
Limitations	This study evaluated the efficiency of county public hospitals in Shanxi	25

	Province and explored the influence of scale on hospital efficiency. It provided a reference for the government and hospitals to reasonably control bed size. However, the study has Only 77 hospitals were chosen in one province, so the extrapolation of this study may be limited.	
Interpretation	<p>1.The Meta-frontier and SBM-undesirable DEA models effectively solved the problem that the efficiency score of hospitals was not on the same production frontier.</p> <p>2.Medical quality index was set as an output indicator in this study, which means that the hospitals should not only focus on the number of patients, but also focus on the medical quality.</p> <p>3.Only 77 hospitals were chosen in one province, so the extrapolation of this study may be limited.</p>	2-3

23 **Abstract**
24

25
26
27 **Objectives** Since the new medical reform in 2009, county-level hospitals in China
28 have achieved rapid development, but health resource waste and shortage issues still
29 exist.
30
31
32

33
34
35 **Design** We applied the Meta-frontier and SBM-undesirable (Slacks-based
36 Measurement-undesirable) DEA(Data Envelopment Analysis) model to measure the
37 medical service efficiency with or without medical quality constraints of the county-
38 level public general hospitals (CPGHs). The assessment includes four inputs, three
39 desirable outputs, and one undesirable output. We conducted the assessment via Max-
40 DEA V.8.19 software. Moreover, we analyze the factors affecting CPGHs' medical
41 service efficiency based on the FRM model.
42
43
44
45
46
47
48
49
50
51

52
53 **Setting** A total of 77 sample CPGHs were selected from Shanxi province in China
54 from 2013 to 2018.
55
56

57
58 **Results** The results of this study showed that the efficiency level of county-level public
59
60

1
2
3
4 hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is
5
6 0.61 without quality constraints and 0.63 under quality constraints). This showed that
7
8 ignoring medical quality constraints will result in lower efficiency and lower health
9
10 resource utilization for high medical quality hospitals. The medical service efficiency
11
12 of CPGHs differs greatly among different regions. Under the meta-frontier, the
13
14 hospitals in the central region had the highest efficiency (efficiency score 0.70),
15
16 followed by those in the south (efficiency score 0.63), and the hospitals in the north had
17
18 the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the
19
20 service efficiency of county public hospitals are the average length of hospital stay, per
21
22 capita disposable income and financial subsidy income.
23
24
25
26
27
28

29
30 **Conclusions** To improve CPGHs' medical service efficiency, the government should
31
32 increase investment in the northern region, and hospitals should improve the
33
34 management level and allocate human resources rationally.
35
36

37
38 **Keywords:** County-level Hospital Efficiency, Medical quality, Meta-frontier DEA
39
40 Model, SBM-Undesirable DEA Model.
41
42
43
44
45

46 **Strengths and limitations of this study**

- 47
48 • This study introduced the the Meta-frontier and SBM-undesirable DEA models to
49
50 measure the efficiency of the county-level public general hospitals (CPGHs) in China.
51
52 This process is advantageous to draw reliable and robust conclusions.
53
54
- 55
56 • Medical quality index was set as an output indicator in this study, which means that
57
58 the hospitals should not only focus on the number of patients, but also focus on the
59
60

1
2
3
4 medical quality.

- 5
6
7 • Due to data unavailability, we only selected the number of doctors, nurses, beds and
8
9 machines as the input variable and did not include staff income, which is a crucial
10
11 input variable.
12
13
14 • Only 77 hospitals were chosen in one province, so the extrapolation of this study may
15
16 be limited.
17
18
19
20
21

22 **Background**

23
24 In March 2009, the Chinese government started a new medical reform. Since the
25
26 implementation of the medical reform, China has made great achievements in
27
28 expanding medical security services [1,2]. The government has vigorously developed
29
30 primary medical and health services and strived to improve the fairness of the health
31
32 service distribution [3]. However, the distribution of health resources in China is still
33
34 unreasonable, and health resources are scarce [4]. High-quality medical resources are
35
36 mainly concentrated in cities, leading to a significant medical quality gap between
37
38 urban and rural hospitals [5-7]. Additionally, patients prefer to choose urban hospitals,
39
40 which leads to the idleness of rural hospital resources [8]. Health resource waste and
41
42 shortage issues have seriously restricted the service ability of medical and health
43
44 institutions and led to low medical efficiency [9]. To solve these problems and improve
45
46 the quality of medical services, the government has implemented a series of reforms in
47
48 rural hospitals [1,10]. China's urban and rural medical system is mainly composed of
49
50 urban tertiary hospitals, urban community hospitals, county-level hospitals and
51
52
53
54
55
56
57
58
59
60

1
2
3
4 township health centers [11]. Among them, county-level public general hospitals
5
6 (CPGHs) act as a link between China's urban and rural medical systems, and they are
7
8 the leaders of rural health institutions [12-14]. Their medical services have a wide range
9
10 of radiation and cover a large population [9]. However, county-level hospitals also have
11
12 problems such as shortages of human resources, low levels of medical services and
13
14 uneven distributions of resources [14-16]. For example, Wu noted that the quality of
15
16 human resources in primary hospitals is not high and the medical service level is poor
17
18 [17]. Jay found that the average resource levels of county-level hospitals in western
19
20 China were lower than those in other regions [18]. Therefore, it is very important to
21
22 improve the utilization rate of primary health resources and the medical efficiency of
23
24 county-level hospitals.
25
26
27
28
29
30
31

32 In recent years, many scholars have studied the medical efficiency of CPGHs in
33
34 China. Li measured the medical efficiency of 12 CPGHs in Anhui Province and found
35
36 that it has declined year by year; additionally, the medical reform effect of CPGHs was
37
38 not significant [19]. Wang analyzed the medical efficiency of 127 CPGHs in China and
39
40 found that the efficiency of CPGHs still has considerable room for improvement [20].
41
42 Jiang conducted a study of 1105 CPGHs in China and noted that although medical
43
44 reform has increased the scale of hospitals, it has not improved the medical efficiency
45
46 of CPGHs [9]. Other scholars' studies have also shown that the medical efficiency of
47
48 CPGHs has room for improvement [12,21,22]. However, in the evaluation of medical
49
50 efficiency, researchers are most likely to ignore the indicators of medical quality, which
51
52 lead to some high efficiency hospitals with low medical quality [23,24]. At present,
53
54
55
56
57
58
59
60

1
2
3
4 medical quality indicators such as mortality rate, infection rate and adverse events are
5
6 often selected as undesirable indicators in hospitals efficiency evaluation [25-27]. In
7
8 SBM-undesirable DEA model, medical quality indicators can be regarded as
9
10 undesirable indicators. For example, SBM-undesirable DEA model was used by A.
11
12 Monzeli to measure the emergency departments , which indicated that the undesirable
13
14 output can determine the hospitals' efficiency [28]. Wei Lu used the SBM-undesirable
15
16 DEA model to measure 77 county-level medical efficiency in China [29]. This model is
17
18 widely used in the field of medical service efficiency evaluation in recent years.
19
20
21
22
23
24

25 In this study, we used the SBM-undersinable DEA model to measure the medical
26
27 efficiency of CPGHs. Moreover, considering the inconsistencies in the internal and
28
29 external environment of the CPGHs area, traditional DEA model can not capture the
30
31 heterogeneity among CPGHs in different area. To solve this problem, we introduced
32
33 the Meta-frontier DEA model [30], which is a mature DEA model to solve heterogeneity,
34
35 to measure the heterogeneity of CPGHs in different area. Therefore, we combined the
36
37 Meta-frontier DEA and SBM-undersinable model to measure the efficiency of the
38
39 CPGHs.
40
41
42
43
44
45
46
47

48 **Methods**

49 **Data Sources**

50
51
52 The data are mainly from the 2013-2018 Shanxi (a province with a population of
53
54 37 million in China) Statistical Yearbook and China Health Statistics Yearbook.
55
56 Overall, 77 CPGHs in Shanxi Province were selected [31]. The data excluded other
57
58
59
60

types of hospitals, such as traditional Chinese medical hospitals, maternal and child health care hospitals and other medical institutions, so they met the homogeneity requirement of the DEA(Data Envelopment Analysis) method.

Meta-frontier and Group Frontier DEA Models

The meta-frontier DEA model was first proposed by Battese [32]. The meta-frontier refers to the potential technical level of all decision making units (DMUs), and the group frontier refers to the actual technical level of each DMU. The difference between them is the different technology sets to which they refer.

According to the meta-frontier DEA model of Battese [33], we took the unexpected output into account. In this case, the technology set (T^{meta}) includes all technically feasible input-output combinations:

$$T^{meta} = \{(x,y,b):x \geq 0,y \geq 0,b \geq 0; \text{ } x \text{ can produce } (y,b)\} \quad (1)$$

In the above formulation, x is the input vector, y is the expected output vector, and b is the unexpected output vector. That is, to obtain a certain output $P^{meta}(y, b)$, the input (x) must be satisfied under the given technological condition (T^{meta}). The production possibility set (meta-frontier) is as follows:

$$P^{meta}(x) = \{(y,b) : (x,y,b) \in T^{meta}\} \quad (2)$$

Therefore, the technical efficiency function of the meta-frontier from the perspective of the output can be expressed as follows:

$$TE^{meta}(x,y,b) = \inf_{\beta} \{\beta > 0 : (y/\beta) \in P^{meta}(y,b)\} \quad (3)$$

According to the different levels of economic development, Shanxi Province is divided into three groups: Northern Shanxi, Central Shanxi and Southern Shanxi ($h=1,$

2, 3). The group technology set is:

$$T^h = \{(x_h, y_h, b_h) : x_h \geq 0, y_h \geq 0, b_h \geq 0; x_h \rightarrow (y_h, b_h)\}, h = 1, 2, 3 \quad (4)$$

The production set is as follows:

$$P^h(x_h) = \{(y_h, b_h) : (x_h, y_h, b_h) \in T^h\}, h = 1, 2, 3 \quad (5)$$

The group technical efficiency ($h=1, 2, 3$) can be expressed as:

$$TE^h(x_h, y_h, b_h) = \inf_{\beta} \{\beta > 0 : (y_h/\beta) \in P^h(y_h, b_h)\}, h = 1, 2, 3 \quad (6)$$

Meta-frontier technology is the envelope curve of the group frontier technology.

So: $T^m = \{T^1 \cup T^2 \cup T^3\}$.

Technology Gap Ratio (TGR)

The technology gap ratio [33] can be expressed by the meta-frontier and group technology efficiency functions (The results are shown in Figure 1):

$$TGR^h(x_h, y_h, b_h) = \frac{TE^{meta}(x, y, b)}{TE^h(x_h, y_h, b_h)}, h = 1, 2, 3 \quad (7)$$

Fig 1 Schematic diagram of common frontier and group frontier

Take R Hospital located in Group3 as an example, then

$$TE^{meta}(R) = \frac{OC}{OA}; TE^h(R) = \frac{OC}{OB}; TGR^h(R) = \frac{TE^{meta}}{TE^h} = \frac{OC/OA}{OC/OB} = \frac{OB}{OA} \quad (8)$$

If the TGR is less than 1 or there are obvious differences between the mean values of TE^{meta} and TE^h , it is necessary to divide the CPGHs into different groups. In contrast, if the TGR is close to 1 or there are no obvious differences between the mean values of TE^{meta} and TE^h , there is no need to divide the CPGHs into different groups.

SBM-undesirable DEA Model

The SBM-undesirable (Slacks-based Measurement-undesirable) DEA model [34] of unexpected output is used to construct the efficiency measurement model under

the meta-frontier and group frontier conditions, and the formula is:

$$\rho^* = \min \frac{1 - \frac{1}{m} \sum_{i=1}^m \frac{s_{i0}^-}{1x_{i0}}}{1 + \frac{1}{s} \left(\sum_{r=1}^{s_1} \frac{s_r^g}{1y_{r0}^g} + \sum_{r=1}^{s_2} \frac{s_r^b}{1y_{r0}^b} \right)}$$

Subject to

$$x_0 = X\lambda + S^-$$

$$y_0^g = Y\lambda - S^g$$

$$y_0^b = Y\lambda + S^b$$

$$L \leq e\lambda \leq U$$

$$S^-, S^g, S^b, \lambda \geq 0. \quad (9)$$

In the above formulation, X , Y and B represent the input and output vectors of different CPGHs each year. The meta-frontier represents 77 county regions, and the group frontier represents different groups in the 77 county regions; s^- , s^g and s^b are slack variables related to the input, expected output and unexpected output, respectively; r represents the r -th DMU; and r^0 represents the DMU to be assessed. The objective function ρ^* decreases with $s_h^-(\forall h)$, $s_r^g(\forall r)$ and $s_r^b(\forall r)$, where $0 < \rho^* \leq 1$.

Because the data are from multiple years, homogeneity for each CPGH and statistical relations should be considered. Therefore, we adopted the global reference model proposed by Pastor and Lovell [35] to calculate the Malmquist index. This model can solve the comparability problem caused by considering different frontiers in efficiency evaluation.

Disease Complexity Adjustment for Discharged Patients

Since the disease complexity varies from hospital to hospital, it is unfair to simply

1
2
3
4 input the approximate number of discharged patients into the input-output index. For
5
6 example, hospitals with high technology levels are likely to treat patients with
7
8 complicated conditions, and these hospitals will take more time to treat such a patient
9
10 than to treat a patient with a mild illness. Hospitals with low technology levels can
11
12 supply health services to patients with mild illness or light symptoms as a result of their
13
14 limited technical capacities, and patients with severe illness may prefer directly seeking
15
16 health services at high-level hospitals. Thus, 1000 patients in hospital-A will all have
17
18 difficult and complicated diseases, and those in hospital-B will have mild diseases.
19
20 However, when performing efficiency evaluation research, if a quantity of units 1000
21
22 is input without considering the complexity of the disease, it would be unfair to
23
24 hospitals with high technical levels. However, the RCI index can be used to adjust the
25
26 numbers of discharged patients according to the average length of stay and bed
27
28 utilization rate [36]. Given the poor quality of the patient records in county-level hospitals,
29
30 we select the RCI index, which provides a reference for efficiency evaluation in
31
32 underdeveloped areas. The specific adjustment methods were as follows:

$$RCI_i = ALoS_i * (OCC_i/OCC_s) \quad (10)$$

33
34
35 In the above formula, $ALoS_i$ refers to the average length of stay in the i -th hospital,
36
37 OCC_i refers to the bed utilization rate of the i -th hospital, and OCC_s refers to the average
38
39 bed utilization rate of all evaluated hospitals. Therefore, the average length of stay will
40
41 be adjusted upward for hospitals with higher bed utilization rates than the average. The
42
43 actual number of discharged patients (P) was adjusted based on the RCI of each hospital,
44
45 and finally, the number of discharged patients (EP) adjusted according to the RCI index
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

was obtained. The formula is as follows:

$$EP = P * (RCI_i/RCI_s) \quad (11)$$

FRM (Fractional Response Model)

The regression equation is:

$$EFFICIENCY_{it} = \beta_0 + \beta_1 \ln INCOME_{it} + \beta_2 \ln POPULATION_{it} + \beta_3 \ln SUBIDY_{it} + \beta_4 \ln DAY_{it} + \beta_5 BEDRATIO_{it} + \beta_6 STAFFRATIO_{it} + \varepsilon_{it} \quad (12)$$

where $EFFICIENCY_{it}$ represents the service efficiency of the hospital i in year t , β_0 is a constant term. $INCOME_{it}$ and $POPULATION_{it}$ represent the per capita disposable income and residents population of the district (county) where the hospital i is located in year t , respectively; $SUBIDY_{it}$, DAY_{it} , $BEDRATIO_{it}$ and $STAFFRATIO_{it}$ represent the subsidy, average length of hospital stay, hospital bed utilization rate and the proportion of health technicians, respectively. ε_{it} is the error term. This paper uses Stata16.0 software for data processing and regression.

To examine the factors that influence the service efficiency of public hospitals, this paper uses the panel Tobit model with right-side restriction for regression. One of the defects of the Tobit model is that it has a strong dependence on distribution and is sensitive to the problem of heteroscedasticity. If the error term does not follow the normal distribution or has a heteroscedasticity issue, the estimation will be inconsistent [37]. In addition, there are some problems in using the Tobit model to analyze the factors of hospital efficiency [38]. In fact, the hospital efficiency in this paper is a natural consequence of the way DEA is defined, and the hospital efficiency measured according to the Non-oriented EBM model is inherently between 0 and 1, which is not

because of the Tobit model that set the efficiency greater than 1 to the value of 1.

Papke and Wooldridge [39] proposed the Fractional Response Model (FRM) in 1996, which overcomes many of the limitations of linear and nonlinear econometric models when studying bounded data. Ramalho et.al. [40] further developed the FRM model. The FRM model is a nonlinear model using the Quasi-Maximum Likelihood Estimation (QMLE). Compared with the Tobit model, the QMLE is asymptotically efficient and consistent because the FRM model does not require distributional or heteroskedasticity assumptions on the DEA score [41]. In addition, the advantages of the FRM model are that it allows a nonlinear relationship between hospital efficiency and its determinants, allows error terms to have autocorrelation, and does not allow the efficiency score to fall outside 0-1, which are in line with the research content of this paper. To this end, this paper uses the Fractional Response Model (FRM) for robustness testing. The specification is:

$$E(y_i|x_i) = G(x_i\beta) \quad (13)$$

where the subscript i represents hospital, x_i are the factors, and β is the parameter to be estimated. $G(\eta) = \exp(\eta)/[1 + \exp(\eta)]$ represents a probability distribution function in the form of Logit whose domain is all real numbers and whose range is (0,1).

Referring to Papke & Wooldridge [39], the log-likelihood equation can be estimated by Quasi maximum likelihood estimation (QMLE):

$$l_i(\beta) = y_i \ln [G(x_i\beta)] + (1-y_i) \ln [1-G(x_i\beta)] \quad (14)$$

Finally, maximize Equation (15) to obtain the value of β in Equation (13).

$$\max_{\beta} \sum_{i=1}^{269} l_i(\beta) \quad (15)$$

Patient and public involvement

No patient involved

Results and Analysis

Variable Selection

The variables were selected according to previous empirical research and the literature [7, 9, 12, 19-22]. Input variables usually include labor and capital [42]. In our study, the numbers of registered doctors and registered nurses were used to represent the elements of human resources as input variables. Beds and equipment valued above 10,000 yuan were used as capital elements. The total visits, the number of discharged patients (EP) adjusted by the RCI and the number of operations were used as output variables. At present, all critically ill patients in counties in China go to urban tertiary hospitals, so there are almost no death cases [43]. Therefore, in this study, the number of adverse events was used to replace the unexpected output variable as a quality index [44]. The descriptive statistics of the input-output indicators are shown in Table 1.

Table 1. Descriptive statistics

Input/output	Variable	Mean	Std. Dev.	Min	Max
Input variables	doctor	95.232	42.017	18	278
	nurse	117.985	71.658	9	390

Desirable output	EP	9607.892	6610.737	756.4231	32707.7
variables	operations	1470.729	1189.186	81	7926
Undesirable output	adverse	68.712	38.462	10	200
variables	events				

Note: The sample size in the model was 462

The variables for FRM, the dependent variable is the service efficiency of public hospitals. As for the independent variables, according to the existing literature and the consideration of data availability and sample size, the following six types of factors affecting the service efficiency of county-level public hospitals were selected for analysis, including (1) External factors: per capita disposable income of residents (county-level economic factor), number of usual residents (county-level population factor); (2) Internal factors: financial subsidy income (hospital-level financial factor), the proportion of health technicians (human resource factor), hospital bed utilization rate (equipment implementation factor), average length of hospital stay (service delivery factor). The summary of variables for FRM is shown in Table 2.

Table 2. Summary of variables for FRM

Variable name	Variable	Definition
Hospital service efficiency	<i>EFFICIEN</i> <i>CY</i>	Service efficiency of each county-level public hospital calculated according to the Non-oriented EBM model
Per capita disposable income (yuan)	<i>INCOME</i>	Per capita disposable income of usual residents

Test and Analysis of the Technology Gap Ratio (TGR)

Under a quality constraint, a mean value comparison test of the obtained technology gap ratio (TGR) was performed, as shown in Table 3. Assuming that the mean value was 1 and the significance level was 95%, the results showed that the average TGR of each group was less than 1. After performing calculations, from 2013 to 2018, the mean value of the hospital TGR in the southern group was at the highest level, close to 1, reaching 0.93, followed by that of the central group of 0.91, and finally that of the northern group at only 0.63. This result indicated that the southern group was closest to the meta-frontier of technology in county-level public general hospitals, followed by the central group and the northern group. Obviously, both the overall TGR and the regional TGR values were significantly different from the assumed mean value of 1. Therefore, the heterogeneity of the division of public hospitals in Shanxi Province was very obvious, and this finding agreed on the conditions of the DEA meta-frontier model; thus, the meta-frontier model could be suitably applied to analyze the results.

Table 3. Comparative test results of the mean value of the technology gap among county-level public general hospitals in northern, central and southern Shanxi Province from 2013 to 2018

Region	Mean TGR	t	P
--------	----------	---	---

North	0.62649	-17.2815	0.000
Central	0.907907	-8.9249	0.000
South	0.9328708	-6.9778	0.000
Entire	0.8494894	-15.6809	0.000

After calculating the efficiency of county-level general hospitals in Shanxi Province under meta-frontier and group frontier conditions, the temporal trends of the technology gaps in the north, central and southern regions under the quality constraint were further compared. The results are shown in Figure 2.

Figure 2 shows that the mean value of the TGR in the southern and central regions of Shanxi Province was high, while that in the northern region was the lowest, indicating that the central and southern regions provide better hospital management and medical levels as a whole than did the northern region; additionally, they are closer to the technological frontier. The mean value of the TGR in the central and southern regions fluctuated at a high level and remained in a basically stable state, but the mean value of the TGR in the northern region considerably changed. Except for a slight increase in the mean TGR in 2016, other years experienced a downward trend, which indicated that the medical level in the northern region decreased and that different frontiers influenced the efficiency of county-level public general hospitals in different regions of Shanxi Province.

Time Series Analysis of the Technical Efficiency of Hospitals

Figures 3A and B show the trend of the average comprehensive efficiency of sample hospitals in Shanxi Province and in three major regions from 2013-2018 under

1
2
3
4 the meta-frontier and group frontier, respectively. Taking the meta-frontier in Figure
5
6 3A as a reference, the overall average medical service efficiency of county-level public
7
8 general hospitals was more than 0.6, and the medical service efficiency in each region
9
10 was relatively stable each year; notably, the efficiency in the northern region displayed
11
12 a slow downward trend. Referring to Figure 3B, the overall average efficiency for the
13
14 group frontier was approximately 0.75, the southern region was relatively stable, and
15
16 the trends in the northern and central regions involved inverted U-shaped curves in the
17
18 early stage; however, all the regions experienced a significant increase in 2018.
19
20
21
22
23
24

25 Figures 3C and D show the trend of the average comprehensive efficiency of the
26
27 sample hospitals in Shanxi Province and in three major regions under the meta-frontier
28
29 and the group frontier conditions, respectively, based on the quality constraints from
30
31 2013 to 2018. Taking the common frontier in Figure 3C as a reference, the overall
32
33 average medical service efficiency of county-level public general hospitals was
34
35 approximately 0.63, and the medical service efficiency trend in various regions
36
37 displayed an inverted U-shaped curve in each year; that is, it fluctuated and rose from
38
39 2013 to 2016 and then dropped rapidly after 2016. Regarding Figure 3D, the overall
40
41 average efficiency under the group frontier was approximately 0.75, and the medical
42
43 service efficiency trend in the northern region displayed a U-shaped curve that
44
45 fluctuated and decreased from 2013 to 2016 and then rose slowly after 2016. Moreover,
46
47 the efficiency trends in the central and southern regions were the same as those for the
48
49 meta-frontier.

57 **Analysis of the Differences in Hospital Technical Efficiency**

58
59
60

1
2
3
4 The distribution of the service efficiency of public general hospitals in Shanxi
5 Province is shown in Figure 4. Graph A shows the distribution of hospital efficiency
6 without quality constraints, and graph B presents the distribution of hospital efficiency
7 under quality constraints. In terms of location, the peak position of the distribution
8 curve in Figure 4B moves to the right compared with that in Figure 4A, indicating an
9 overall efficiency improvement. The kurtosis of the distribution curve for the central
10 and southern regions in Figure 4B is greater than that in Figure 4A, indicating that the
11 distribution of the efficiency was more concentrated in B. The northern distribution
12 curve in Figure 4B displays an obvious bimodal state, indicating that the efficiency
13 distribution was somewhat scattered. Therefore, quality constraints were very
14 important in the hospital efficiency evaluation. A lack of quality constraints would lead
15 to certain deviations in the evaluation results, and the results would not
16 comprehensively reflect the actual operation status of the medical system.

17
18
19 An analysis of the hospital efficiency distribution in Figure 4B was performed.
20 First, for the location, the distribution curves of the hospital efficiency density in the
21 northern, southern and central regions sequentially moved to the right. The distribution
22 curves of the southern and central regions were closely interlaced, indicating that the
23 hospital efficiency levels in the southern and central regions are similar and
24 significantly higher than the level in the northern region.

25
26
27 Second, the distribution curve of the efficiency density in northern hospitals peaks,
28 and the distribution curves of the efficiency density for the central and southern
29 hospitals displays broad kurtosis.

1
2
3
4 Finally, in terms of shape, the distribution curve of the efficiency density for
5
6 northern hospitals is bimodal, and those for the central and southern hospitals are
7
8 unimodal, suggesting that most hospitals in the central and southern regions have little
9
10 difference in medical level, while the medical level of northern hospitals is polarized;
11
12 this relation reflects the concept of “the strong get stronger, and the weak get weaker”
13
14
15
16
17 (Matthew's effect).

18 **Analysis of the Changes in Hospital Technical Efficiency Rankings**

19
20 To show the changes in efficiency among the sample hospitals before and after the
21
22 implementation of quality constraints, the comprehensive efficiency values of sample
23
24 hospitals under the two constraint conditions were ranked, and the changes in hospital
25
26 rankings were compared. The results are shown in Figure 5. In the northern region, the
27
28 ranking of hospital 17 increased the fastest, and the rankings of hospitals 6 and 13
29
30 decreased most obviously. In the central region, the ranking of hospital 24 increased
31
32 the fastest, and the ranking of hospital 29 decreased the most. In the southern region,
33
34 the ranking of hospital 71 increased the fastest, and the ranking of hospital 67 decreased
35
36 the most.
37
38
39
40
41
42
43

44
45 By analyzing the unexpected outputs of adverse events at hospitals, it was found
46
47 that the changes in efficiency rankings were related to the unexpected outputs of
48
49 adverse events; notably, the efficiency ranking increased when the unexpected output
50
51 level was low, and the ranking decreased when the unexpected output level was high.
52
53 For example, the average unexpected output of hospitals in the northern region was -
54
55 14.35, and that of hospital 17, with a medical quality higher than that of most hospitals,
56
57 was -3.38. However, the average unexpected outputs of hospitals 6 and 13 were -23.78
58
59
60

and -31.08, respectively, and the corresponding medical quality was lower than that of other hospitals. Additionally, the average unexpected output values of hospitals in the central and southern regions were -15.3 and -19.22, respectively, and the average unexpected output values of hospitals 24 and 71 were only -3.09 and -3.49, respectively. Moreover, the average unexpected output values of hospitals 29 and 67 were -23.99 and -57.25, respectively.

The Spearman rank correlation test was used to determine whether there was a correlation between the hospital efficiency values under the two different constraints. The significance level was 1%. The results showed that there was a positive correlation between the efficiency values of sample hospitals under the two constraints. According to the results, the three regions were different: the southern region had the highest similarity, with a correlation coefficient of 0.9673, and the greatest difference was observed in the northern region, with a correlation coefficient of 0.8452.

Analysis of factors affecting public hospital efficiency

The result on factors affecting public hospital efficiency based on the FRM model is shown in Table 4.

Table 4. Regression result of the FRM model

	(1)FRM-Logit	(2)FRM-Logit
<i>Constant</i>	-63.1201 (57.5153)	174.6323** (69.2530)
<i>ln INCOME</i>	23.9425*** (8.0147)	57.9482*** (9.1432)
<i>ln POPULATION</i>	11.7407** (4.8335)	18.0447*** (4.9030)
<i>ln SUBSIDY</i>	18.2966*** (2.1988)	13.6022*** (2.1659)
<i>ln DAY</i>	-53.1396*** (8.9505)	-53.4437*** (8.9724)
<i>BEDRATIO</i>	1.8526*** (0.1080)	1.8717*** (0.1104)
<i>STAFFRATIO</i>	4.3761*** (1.1724)	3.9982*** (1.1333)

Wald test	570.78(0.0000)	758.54(0.0000)
Time fixed effect	No	Yes
County fixed effect	No	Yes
Hospital category effect	No	Yes
Observations	1430	1430

Note: The data in parentheses after each coefficient is the standard deviation. To facilitate comparison with the Tobit model, both coefficients and standard deviation are multiplied by 100. In the Wald test, the values on the left side of the parentheses are the values of χ^2 distribution, and the values in the parentheses are the corresponding P values. ***, **, and * represent 1%, 5%, and 10% significance level, respectively.

We can find that the coefficient of per capita income is positive and significant, that is, the improvement of residents' per capita disposable income can improve the service efficiency of county public hospitals; Population factor negatively impacts public hospital efficiency when the fixed effects are not controlled. After controlling for the fixed effects, the coefficient is significantly positive, that is, the resident population in the county where the hospital is located is positively correlated with the service efficiency of county public hospitals; The effect of financial subsidy income on the service efficiency of county public hospitals is significantly positive; The coefficient for the average length of hospital stay is the largest and significantly negative; And the proportion of health technicians has a significant positive impact on the service efficiency of public hospitals.

Discussion

This paper used the meta-frontier model and SBM-undesirable (Slacks-based Measurement-undesirable) model to calculate the efficiency of county-level public hospitals in Shanxi Province from 2013 to 2018. Then, we evaluated the reform effect and resource utilization rate of county hospitals and explored the influence of medical

1
2
3
4 quality on hospital efficiency. Moreover, we analyze the factors affecting public
5
6 hospital efficiency based on the FRM model.
7

8
9 The results of this study showed that the efficiency level of county-level public
10
11 hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is
12
13 0.61 without quality constraints and 0.63 under quality constraints). In other studies,
14
15 the average efficiency of county hospitals in Chongqing was 0.83 [12], in Anhui
16
17 Province was 0.956 [19], and in China, as a mean value, was 0.7 [20], suggesting that
18
19 the efficiency of county-level hospitals in Shanxi Province is obviously low;
20
21 additionally, the utilization rate of existing resources is relatively low, and the
22
23 technology used is inefficient. To improve the efficiency level of county-level hospitals,
24
25 in addition to increasing investments to alleviate resource shortages, it is necessary to
26
27 improve the utilization efficiency of resources, such as improving hospital management,
28
29 rationally allocating human resources, and optimizing capital investments [45].
30
31
32
33
34
35
36
37

38 The results showed that the efficiency of county-level public hospitals in Shanxi
39
40 Province did not improve and even declined in some areas from 2013 to 2018 (Figure
41
42 2C). Although the reform of county-level hospitals was initiated in 2012, the effect was
43
44 not remarkable, as also noted by Jiang et al. [9]. Moreover, the study found that there
45
46 were regional differences in the efficiency of county-level public hospitals in Shanxi
47
48 Province. The efficiency level of county-level public hospitals in the central and
49
50 southern regions of Shanxi Province was high, while the efficiency level in the northern
51
52 region was comparatively low (Figure 2A and Figure 2C); these trends were also
53
54 reflected by the technology gap ratio distribution in each region (Figure 1), which
55
56
57
58
59
60

1
2
3
4 indicated that the county-level hospitals in the northern region were far from the
5
6 technological frontier. Therefore, increasing the resource inputs for hospitals in the
7
8 northern region of the province should be prioritized to improve their medical levels.
9
10 Additionally, the population and economic level in northern Shanxi Province are lower
11
12 than those in the central and southern regions [46]; thus, hospital efficiency may be
13
14 related to the economic environment and population.
15
16
17
18

19
20 This study also showed that quality constraints had an important impact on
21
22 hospital efficiency evaluation (Figures 3 and 4). Neglecting medical quality output
23
24 could lead to underestimates of the hospital efficiency level. This finding could
25
26 potentially be attributed to the fact that medical quality is often related to hospital
27
28 management and human resources [47]. With improvements in hospital management
29
30 and medical treatment ability, medical quality will also increase, as will the
31
32 corresponding hospital efficiency. Improving the quality of medical services is often
33
34 the goal of public hospitals [48], but many hospitals begin to expand blindly, resulting
35
36 in inefficiency [20,41,49]. Pang [50] et al. noted that improperly scaled expansion can
37
38 lead to technical efficiency in the short term but not in the long term. Therefore, to
39
40 improve the medical quality level, increasing the technological capacity and improving
41
42 management are steps.
43
44
45
46
47
48
49

50
51 For the factors that influence public hospital efficiency, firstly, when the per capita
52
53 disposable income of residents is high, people may pay more attention to their health,
54
55 and have more requirements for the service and technical level of the hospital.
56
57 Accordingly, health services will be used more rationally. Secondly, the more resident
58
59
60

1
2
3
4 population in the region, the greater the intensity of the demand for medical services,
5
6 and the hospital will continuously improve its medical service to meet the demand, thus
7
8 making the hospital service more efficient. The reason for the low level of significance
9
10 level is that: on the one hand, the resident population is the macro-level data, which has
11
12 little impact on the efficiency of the micro-level hospital; on the other hand, the mobility
13
14 of people seeking medical treatment is high, so the population of the area where the
15
16 hospital is located has limited effect on the efficiency of the local hospital. Thirdly, if
17
18 the government increases the financial investment in the hospital, it will help the
19
20 hospital to introduce high-tech equipment and improve the hospital's infrastructure
21
22 construction capacity, etc. Thus it will prompt the hospital to realize the rational
23
24 allocation of resources under the guidance of the government's policy of increasing the
25
26 corresponding investment. As a result, the hospital achieves more efficient health
27
28 service, improving the efficiency of hospital services. Fourthly, the average length of
29
30 hospital stay is an important factor affecting the service efficiency of public hospitals,
31
32 and a longer length of hospital stay will reduce the service efficiency level of the
33
34 hospital. This may be because a longer length of hospital stay means hospitals are not
35
36 treating patients in a timely manner or have to deal with more severe cases, making
37
38 hospital services less efficient. Fifthly, the bed utilization rate reflects the vacant beds
39
40 in the hospital. The higher the hospital bed utilization rate, the more patients can be
41
42 provided with hospital-stay services at the same time, thereby increasing the hospital-
43
44 stay service output and improving the hospital's service efficiency. Sixthly, for the
45
46 positive impact of the proportion of health technicians, the reason may be that the higher
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 the proportion of health technicians, the higher the level of medical service, and the
5
6 further improvement of the service efficiency of the hospital.
7

8 9 **Limitations and suggestions for future research**

10
11 This study evaluated the efficiency of county public hospitals in Shanxi Province
12 and explored the influence of scale on hospital efficiency. It provided a reference for
13
14 the government and hospitals to reasonably allocate health resources. However, we
15
16 believe that our research can be improved and extended in a number of directions. First,
17
18 the study has Only 77 hospitals were chosen in one province, so the extrapolation of
19
20 this study may be limited. Future studies can be conducted and include CPGHs in other
21
22 provinces, which are divided by region. Second, we did not include the staff salary as
23
24 the input variable, mainly due to data limitations. However, further analysis focusing
25
26 on the staff salary variable is also necessary given that we are studying public hospitals'
27
28 efficiency, the salary paid to employees by the government is an important input
29
30 indicator for evaluating public hospitals' efficiency.
31
32
33
34
35
36
37
38
39

40 **Conclusion**

41
42 This showed that after the implementation of county-level public hospital reform,
43
44 the efficiency level of county-level public hospitals in Shanxi Province did not improve
45
46 but remained low. Notably, the utilization rate of resources was low, and the reform
47
48 effect was not obvious. There are differences in the efficiency of county-level hospitals
49
50 in different regions, with the highest efficiency in the central region, the second-highest
51
52 level in the southern region and the lowest level in the northern region. To improve the
53
54 efficiency of hospitals, support to the northern region should be strengthened, hospital
55
56
57
58
59
60

1
2
3
4 management should be improved, and health human resources should be rationally
5
6 allocated.
7
8

9 The results also indicated that quality factors have a significant impact on hospital
10 efficiency evaluation. The keys to improving the level of medical quality are to improve
11 the proportion of technical personnel and the level of hospital management. The
12 expansion of county-level hospitals should consider the economic level and service area
13 in the region to avoid expansion and blind investment, potentially resulting in wasted
14 resources.
15
16
17
18
19
20
21
22
23

24 According to the FRM regression results, it is concluded that the factors that have
25 larger impacts on the service efficiency of county public hospitals are the average length
26 of hospital stay, per capita disposable income and financial subsidy income. Shortening
27 the average hospital stay can improve hospital efficiency. In areas with higher per capita
28 disposable income of residents, the service efficiency of county-level public hospitals
29 is higher. And the increase in subsidy has a positive effect on the improvement of
30 hospital service efficiency. In addition, the county population, bed utilization rate and
31 the proportion of health technicians also have significant impacts on hospital service
32 efficiency. The higher the population, the higher the hospital efficiency. Increasing the
33 bed utilization rate and the proportion of health technicians will also promote hospital
34 service efficiency. However, only 77 hospitals in one province were selected for this
35 study, so the extrapolation from this study may be limited.

Authors' contribution

All authors made significant contribution to this study. JL conceptualized the study. WL collected and analyzed the data. BBG wrote the first draft of the manuscript. XJH, HKW and GYZ interpreted the results and revised the manuscript. The final version submitted for publication was read and approved by authors.

Funding

This study was supported by the Research and cultivation fund of Hainan Medical College (HYPY2020025) and National Natural Science Foundation of China(72204069).

Data Availability Statement

Data are available in a public, open access repository.

i) The data are mainly from the 2013-2018 Shanxi Statistical Yearbook and China Health Statistics Yearbook, Overall 77 CPGHs in Shanxi Province(a province with a population of 37 million in China) were selected.

ii) The data is held in Baidu web disk. (Link: <https://pan.baidu.com/s/1OaqcOy0GVwuHJYQXilcMXQ?pwd=0qsf>; Extraction code: 0qsf)

iii) There are no reuse conditions for the data.

Ethics approval and consent to participate

As the descriptive research of this study is an analysis of existing data, which does

1
2
3
4 not involve human participants, so there are no ethics approval is required from the

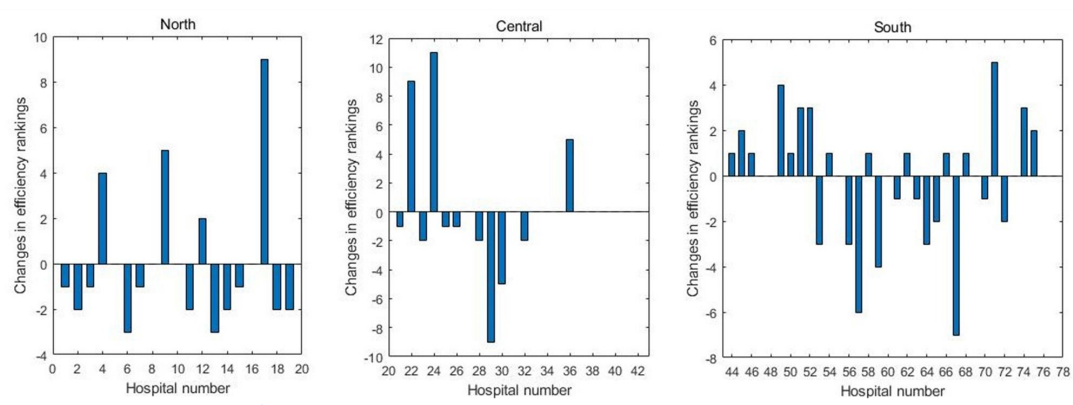

Fig.5 Charges in the efficiency ranking of county-level public general hospitals in Shanxi Province before and after the implementation of quality constraints

STROBE checklist

	Recommendation	page
Title and abstract	<p>Study of the Medical Service Efficiency of County-Level Public General Hospitals Based on Medical Quality Constraints: a cross-sectional study</p> <p>Objectives: Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.</p> <p>Methods: Based on the data from 77 county-level public general hospitals (CPGHs) in Shanxi Province, China, from 2013-2018, we applied the meta-frontier and SBM-undesirable (Slacks-based Measurement-undesirable) DEA(Data Envelopment Analysis) model to measure the CPGHs' medical service efficiency with or without medical quality constraints and evaluate the effects of the new medical reform to explore the utilization of health resources and look for ways to improve the CPGHs' medical service efficiency. Moreover, we analyze the factors affecting public hospital efficiency based on the FRM model.</p> <p>Results : The results of this study showed that the efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This showed that ignoring medical quality constraints will result in lower efficiency and lower health resource utilization for high medical quality hospitals. The medical service efficiency of CPGHs differs greatly among different regions. Under the meta-frontier, the hospitals in the central region had the highest efficiency (efficiency score 0.70), followed by those in the south (efficiency score 0.63), and the hospitals in the north had the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income.</p> <p>Conclusion: To improve CPGHs' medical service efficiency, the government should increase investment in the northern region, and hospitals should improve the management level and allocate human resources rationally.</p>	1-2
Introduction		
Background/rationale	<p>Background: 1. In China, county-level hospitals are divided into CPGHs, traditional Chinese medical hospitals, and maternal and child health care hospitals. However, most studies do not subdivide the hospitals by type, and different types of hospitals have different resource allocation and output structures.</p> <p>2. In China, most studies have not considered the differences in production frontiers due to the different natural, social and economic environments in different regions. However, in other industries, some relevant scholars have added relevant non-expected output indicators for research when evaluating efficiency.</p> <p>3. Ignoring the constraints of medical quality, which is an unexpected output of DEA, will seriously affect hospital efficiency. However, In China, many studies have not considered the issue of unexpected output.</p> <p>Rationale: 1. This study used the meta-frontier DEA model to evaluate the medical efficiency of CPGHs in different regions and it can solve the problem</p>	4-6

	of technical heterogeneity; 2. This study selected "adverse events" as a medical quality indicator. And used the SBM-undesirable DEA model is to solve the problems related to unexpected outputs categorized as "adverse events".	
Objectives	Since the new medical reform in 2009, county-level hospitals in China have achieved rapid development, but health resource waste and shortage issues still exist.	1
Methods		
Study design	a cross-sectional study	1
Setting	The data are mainly from the 2013-2018 Shanxi (a province with a population of 37 million in China) Statistical Yearbook and China Health Statistics Yearbook. Overall, 77 CPGHs in Shanxi Province were selected	6
Variables	Input variables: doctor、 nurse、 bed and machine; Desirable output variables: treatment、 EP and operations; Undesirable output variables: adverse events	13
Data sources/ measurement	The data are mainly from the 2013-2018 Shanxi (a province with a population of 37 million in China) Statistical Yearbook and China Health Statistics Yearbook. Overall, 77 CPGHs in Shanxi Province were selected. The data excluded other types of hospitals, such as traditional Chinese medical hospitals, maternal and child health care hospitals and other medical institutions.	6
Results		
Main results	The efficiency level of county-level public hospitals in Shanxi Province is relatively low overall (the mean value of efficiency is 0.61 without quality constraints and 0.63 under quality constraints). This showed that ignoring medical quality constraints will result in lower efficiency and lower health resource utilization for high medical quality hospitals. The medical service efficiency of CPGHs differs greatly among different regions. Under the meta-frontier, the hospitals in the central region had the highest efficiency (efficiency score 0.70), followed by those in the south (efficiency score 0.63), and the hospitals in the north had the lowest efficiency (efficiency score 0.54). Factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income.	1-2
Discussion		
Key results	According to the FRM regression results, it is concluded that the factors that have larger impacts on the service efficiency of county public hospitals are the average length of hospital stay, per capita disposable income and financial subsidy income. Shortening the average hospital stay can improve hospital efficiency. In areas with higher per capita disposable income of residents, the service efficiency of county-level public hospitals is higher. And the increase in subsidy has a positive effect on the improvement of hospital service efficiency. In addition, the county population, bed utilization rate and the proportion of health technicians also have significant impacts on hospital service efficiency. The higher the population, the higher the hospital efficiency. Increasing the bed utilization rate and the proportion of health technicians will also promote hospital service efficiency.	25-26
Limitations	This study evaluated the efficiency of county public hospitals in Shanxi	25

	Province and explored the influence of scale on hospital efficiency. It provided a reference for the government and hospitals to reasonably control bed size. However, the study has Only 77 hospitals were chosen in one province, so the extrapolation of this study may be limited.	
Interpretation	<p>1.The Meta-frontier and SBM-undesirable DEA models effectively solved the problem that the efficiency score of hospitals was not on the same production frontier.</p> <p>2.Medical quality index was set as an output indicator in this study, which means that the hospitals should not only focus on the number of patients, but also focus on the medical quality.</p> <p>3.Only 77 hospitals were chosen in one province, so the extrapolation of this study may be limited.</p>	2-3
