ABSTRACT

Introduction: Ginger-salt-indirect moxibustion is widely applied to treat urge urinary incontinence after stroke, which is a common complication in stroke survivors. Moxa cone moxibustion and moxa box moxibustion are the main techniques of ginger-salt-indirect moxibustion. Our previous study had shown that ginger-salt-indirect moxibustion using moxa cones was feasible and effective for urination disorders post-stroke. This pilot study aims to assess the feasibility of conducting research to evaluate the efficacy and safety of ginger-salt-indirect moxibustion for patients with post-stroke urge urinary incontinence.

Methods and analysis: This is a multicentre, prospective, single-blinded, pilot randomised controlled trial. 120 eligible patients will be randomly allocated to three groups. Treatment group A (n=40) will receive moxa cone moxibustion and routine care; treatment group B (n=40) will receive moxa box moxibustion and routine care; control group (n=40) will only receive routine care for stroke recovery. The entire moxibustion treatment will consist of a total of 28 sessions during the course of 4 weeks. The primary outcome measure will be the increase in mean volume per void assessed at week 4 from the first moxibustion session (baseline). Secondary outcome measures will include mean frequency of urination per day and quality of life assessments measured by completion of the Incontinence Quality of Life Questionnaire and Barthel Index. All outcome measures will be assessed at baseline and at 4 and 16 weeks from baseline. Adverse events in the three groups will be recorded to assess the safety of moxibustion.

Ethics and dissemination: Research ethics was approved by the Research Ethical Committee of Beijing Hospital of Traditional Chinese Medicine Affiliated to the Capital Medical University (ref: 2013BL-094). Written informed consent will be obtained from all participants. Study results will be published in peer reviewed journals.

Trial registration number: ISRCTN 44706974.

Strengths and limitations of this study

- First pilot study to evaluate the feasibility of conducting research to assess the efficacy and safety of ginger-salt-indirect moxibustion as treatment for urge urinary incontinence after stroke.
- Multicentre, randomised controlled trial with pragmatic design.
- Interventions conducted by certified acupuncturists according to the STRICTOM and good clinical practice guidelines (GCP).
- Lack of blinding of acupuncturists and participants due to the nature of moxibustion.

INTRODUCTION

Urinary incontinence (UI) is defined by the International Continence Society (ICS) as involuntary leakage of urine that causes hygienic or social problems.¹ The prevalence of UI after stroke varies from 32–79% at admission,^{2–4} 25% at hospital discharge, and 15% after 1 year.⁴ Urge urinary incontinence (UUI) is a common type of UI⁵ that occurs after stroke. It is characterised by involuntary leakage of urine accompanied or preceded by urgency.¹

The results of a previous review⁶ suggested that there were three major causes of UI after stroke: detrusor hyperreflexia caused by infarction; stroke-related cognitive or language deficits; and bladder hyporeflexia with resultant overflow incontinence. UUI can be caused by detrusor overactivity due to the loss of inhibitory neurones after stroke.⁷ Detrusor overactivity is characterised by involuntary detrusor contractions during the filling and storage phase.^{1 7 8} When intradetrusor pressure generated by abnormal

detrusor contractions exceeds sphincter pressure, UI occurs.⁷ UI is a strong prognostic indicator for stroke recovery, which is associated with high rates of mortality,^{9–10} disability¹¹ and increasing admission to institutional care.¹² Micturition disorders may result in urinary infection, nephritis, fungal dermatitis,¹³ and even bedsores. Typical symptoms, including frequent micturition, nocturia and urgency, could lead to impaired quality of life¹⁴ and heavy economic burden.^{15–16}

Initial treatments for UUI after stroke recommended by ICS are behavioural therapy and pharmacotherapy.¹ Behavioural therapies, including healthy bladder habits and training techniques, are aimed at changing patient lifestyle and at teaching patients to control urgency and enhance continence ability.¹⁷ For habit modification, patients are given guidance on how to re-establish a healthy voiding schedule, eliminate bladder irritants from the diet, manage fluid intake and bowel regularity, control weight, and give up smoking.^{18–24} Training techniques consist of bladder training, urgency control techniques, pelvic muscle exercises, delayed voiding, and multicomponent behavioural training.¹⁷ Behavioural interventions are applied in the primary care setting, with or without pharmacotherapy.^{25–27} Among these strategies, behavioural training and bladder training have the strongest evidence of efficacy for the treatment of UUI.^{28–31}

Antimuscarinic drugs can reduce urgency and improve bladder function by controlling detrusor muscle overactivity through inhibition of M2 and M3 muscarinic bladder receptors.^{32–34} Several meta-analyses have shown that the most widely used antimuscarinic drugs have significant clinical benefits on UUI.^{35–38} However, use of antimuscarinic agents is complicated by dose convenience, drug contraindication, and financial concerns.³⁹ A Cochrane systematic review⁴⁰ concluded that no studies designed to manage UI after stroke in secondary care had been rigorously conducted so far. Although there are clinical guidelines for the management of UI after stroke,¹ to date there is insufficient good quality evidence to support current clinical practices.⁴¹ More available therapies and well-designed studies are required to provide further evidence for management of UUI after stroke.

Moxibustion is a therapy that uses ignited materials (usually moxa) to heat selected points of the skin surface. This therapy is widely used for chronic deficiency diseases⁴² and is commonly indicated for UUI.⁴³ The mechanism of action of moxibustion combines thermal, radiation and pharmacological effects of the materials used, acting on the meridian system.⁴⁴ Following the theory of Traditional Chinese Medicine (TCM), kidney *qi* regulates voiding function and ensures voluntary urination. Deficiency of kidney *qi* is known to be the primary pathogenesis of UI according to 'ZhuBingYuanHouLun' (a famous ancient TCM literature). Ginger and salt are typically used on *Shenque* (CV8) acupoint to warm, tonify and nourish the kidney

qi, thereby controlling the bladder and regulating voiding function.

Moxa cone moxibustion and moxa box moxibustion are primary techniques of ginger-salt-indirect moxibustion, which are commonly used in clinical practices in China. Moxa cone moxibustion involves a moxa cone burning directly on the ginger slice and providing thermal stimulus to the skin surface. Moxa box moxibustion facilitates manipulations and reduces adverse reactions by using the moxa box device with moxa sticks inside over the ginger slice. Results of our previous study⁴⁵ showed that ginger-salt-partitioned moxibustion with moxa cone could reduce mean daytime and nighttime voiding frequency in the treatment of urination disorders post-stroke. In addition, we also observed that ginger-salt-indirect moxibustion with moxa cones could increase mean volume per void of UI after stroke in an unpublished study. Our previous studies, together with results from an earlier Cochrane review,^{40–45} suggest ginger-salt-indirect moxibustion may be worth investigating with more rigorous study design.

METHODS

Objectives

This pilot study aims to evaluate the feasibility of research to assess the efficacy and safety of ginger-salt-indirect moxibustion for the treatment of UUI after stroke.

Recruitment

This is a multicentre, single-blinded, pilot randomised controlled trial. The research consists of three sequential parts (figure 1): a recruitment period before randomisation, a treatment period of 4 weeks, and a follow-up period of 12 weeks. One hundred and twenty eligible participants will be recruited from acupuncture wards of three hospitals according to the inclusion and exclusion criteria. During the first visit, potentially qualified patients will be provided with detailed information about this study, including the research objective, study procedure, potential benefits and risks. If a patient shows willingness to participate, they will be required to voluntarily sign a written informed consent. This will be followed by baseline assessment and randomisation.

Design

Randomisation and allocation concealment

The randomisation scheme is provided by the Research Center of Clinical Epidemiology Affiliated to Peking University Third Hospital in China. Statistical experts will use the block randomisation method (block size of 6) of the SAS package (V.9.1.3; SAS institute Inc, Cary, North Carolina, USA) to form the random allocation sequence. Then computer-generated opaque sealed envelopes, each with the serial number outside and group number inside, will be produced. The envelopes will be kept in a secure locked drawer making it inaccessible to all study personnel. After baseline assessments,

Figure 1 Trial flowchart.

the envelopes will be opened sequentially by an independent researcher in front of the participants to ensure adequate concealment. Participants will be allocated to three groups according to the group number printed inside the envelopes.

Blinding

Due to the nature of moxibustion, it is difficult to ensure the therapists or participants are blinded to the treatment allocation. Data managers and statisticians will be blinded throughout the trial. During the intervention, therapists and data managers will be requested not to communicate with each other about the allocation. Blinded telephone interviewers will collect the follow-up materials to evaluate the long term effect of moxibustion at 16 weeks after the baseline.

Participants

Sample size

Because this is a pilot study, a power calculation to determine the sample size was not conducted. Sample size calculation was performed based on estimates of the number of participants we would expect to recruit within 24 months. We therefore plan to recruit five participants per month, according to our previous trial. A sample size of 40 per group and a total number of 120 will be included, which is larger than the minimum of 12 per group suggested for pilot studies.⁴⁶ Outcomes of this pilot study will help calculate the appropriate sample size for further randomised clinical trials.

Inclusion criteria

1. Male or female, aged 40–75 years
2. Inpatients with UII after stroke, according to the diagnosis criteria of the American Stroke Association and the ICS
3. 4th to 48th week after stroke onset
4. Normal consciousness, communication ability and recognition
5. Written informed consent.

Exclusion criteria

1. UII caused by spinal injury, multiple sclerosis or hyperplasia of the prostate gland
2. Chronic urinary retention or UI before stroke onset
3. Stress UI, mixed UI and chronic urinary tract infection
4. Insufficiency of heart, liver, kidney organs
5. Participants in another clinical trial.

Discontinuation criteria

Reasons for discontinuation of treatment may include, but are not limited to, the following:

1. Participant's decision to discontinue treatment at any time for any reason
2. Investigator's determination to discontinue treatment for the patient's safety and best interests at any time
3. Non-compliance of participants with the study procedure (eg, study visits)
4. Concomitant therapy that could affect the study results during the trial
5. Detection of protocol violations at any time.

Intervention

Ginger-salt-indirect moxibustion is formulated on the basis of descriptions in the ancient literature and our clinical experience. Moxibustion will be manipulated by certified acupuncturists with at least 20 years' clinical experience. All treatment details will be standardised between practitioners by guiding videos and relative training before the first acupuncture session. Interventions will be performed in accordance with the STRICTOM⁴⁷ and good clinical practice guidelines (GCP).

Treatment group A

Participants in treatment group A will receive moxa cone moxibustion and routine care once a day for 4 weeks. The procedure for each session as it is used in normal practices is as follows (figure 2). Participants are asked to lie on a bed in a supine position and remove clothing to fully expose the navel in a temperature controlled room (25–30°C). A certain amount of salt is put on the navel to cover *Shenque* (CV8) acupoint and is covered by a fresh slice of ginger (30 mm in diameter and 4–5 mm in thickness). Then a moxa cone (pure wormwood fibre in material, 15 mm in diameter and 30 mm in length; Tongrentang Inc, China) is placed on the fresh ginger slice and lit by the therapist. Once the moxa cone is burnt out, the therapist removes the whole moxa cone and replaces it with another one. The technique requires the participant to experience a sensation of heat but no painful burning sensation. If participants feel pain or a burning sensation, the ginger slice with burning moxa cone will be removed immediately and reset after several minutes. Each session requires three units of moxa cone. The therapist is required to observe the patient carefully and quickly remove the burning ash to avoid injury. Because this study is designed to evaluate moxibustion treatment as it is used in normal practice, the moxibustion group will also receive the usual care provided to the control group.

Treatment group B

Participants in treatment group B will receive moxa box moxibustion and routine care once a day for 4 weeks. The manipulations are generally similar to those in treatment group A. The only difference is that the double-hole moxa box (13×8×8.5 cm) with two moxa sticks (pure wormwood fibre, 15 mm in diameter and 70 mm in length; Tongrentang Inc, China) in the holes will be placed on the fresh ginger slice (figure 3). The moxa sticks will be ignited from the bottom. If patients feel pain, the therapist will remove the lid with the moxa sticks for several minutes. Each session requires three units of moxa sticks.

Control group

According to pragmatic design, the control group will receive routine therapies for stroke recovery. These include control of blood pressure, inhibition of platelet

aggregation, routine physiotherapy, occupational therapy, and glucose control treatment. It will be suggested to the participants in this group that they maintain their normal lifestyle, including diet, exercise and workload. Moreover, participants will be encouraged to inform the researchers of any new treatments performed after entry into the trial.

Outcome measures

Primary outcome measure

The primary outcome measure will be the increase in mean volume per void at week 4 from the baseline.

Mean volume per void is one of the main quantitative indicators recorded in bladder diaries or frequency volume charts.^{17 31 48–50} It is calculated by dividing the total volume of voluntary urination by the total frequency of voluntary urination, based on 72 h frequency-volume chart data. The increase in mean volume per void objectively reflects an improvement in bladder capacity and detrusor stability in the urine filling and storage period. In a previous study, we observed that mean volume per void increased in the ginger-salt-indirect moxibustion group compared to the control group, the difference being statistically significant. Consequently, we selected the increase in mean volume per void at week 4 from baseline as the primary outcome. We will also assess the increase in mean volume per void at week 16 from baseline to evaluate long term efficacy.

Secondary outcome measures

1. The mean frequency of urination per day, including voluntary and incontinence urination.
2. Quality of life assessments measured by completion of the Incontinence Quality of Life Questionnaire (I-QOL)⁵¹ and the Barthel Index (BI).⁵²

The average frequency of urination per day is composed of mean frequency of voluntary and incontinent urination, which represents the severity of frequent micturition and UI, respectively. This is strongly linked to the stability of the bladder and detrusor. Questionnaires for quality of life assessment will be completed based on the objective condition and subjective sensation of the participants.

All outcome measures will be assessed before the baseline, and at 4 and 16 weeks from the baseline.

Adverse events

Adverse events (AEs) are defined as negative or unintended clinical manifestations following the treatment. Participants will be instructed to report any abnormal reactions to the clinical research team at any time. In addition, study investigators will collect information about abnormal reactions weekly by visiting the participants. All details of related and unexpected AEs, such as time of occurrence, degree of AE, and suspected causes, will be recorded on Case Report Forms (CRFs). The common AEs related to moxibustion include allergy,

Figure 2 Moxa cone moxibustion.

burn and infection.⁵³ AEs will be classified into five grades: mild (asymptomatic or mild symptoms; clinical or diagnostic observations only; intervention not indicated); moderate (minimal, local or non-invasive intervention indicated); severe (severe or medically significant but not immediately life-threatening; hospitalisation or prolongation of hospitalisation indicated); very severe (life-threatening consequences; urgent

intervention indicated); death related to AEs. Participants with mild and moderate AEs will receive symptomatic treatment and will be closely followed up by the research team. Severe AEs will be reported to the Research Ethics Committee within 48 h. The Research Ethics Committee will offer medical advice to the research team and determine whether the patient is eligible for further treatment.

Figure 3 Moxa box moxibustion.

Data management

Before recruitment, the whole research group, including therapists, data administrators and outcome assessors, will participate in a training seminar about research contents and data management. Baseline characteristics of participants will be recorded on CRFs by a research assistant. Data collection of urination and questionnaires will be conducted by a researcher who remains blinded to the group allocation at the baseline, 4 and 16 weeks from the baseline. Occupational caregivers will be trained to identify UI and voluntary urination. Caregivers will collect urine following voluntary urination and measure it with a pot-shaped urine collector with scales. They will be trained to record accurate voiding time, voluntary urinary volume and UI episodes on a 72 h frequency–volume chart (figure 4). The record will be started at 8:00 and last for 72 h. If caregivers failed to collect urine in time, they will note voiding time and specific reasons on the chart. The blinded researcher will complete the urination section on CRFs according to the 72 h frequency–volume charts handed in by caregivers.

Two independent researchers blinded to the group allocation will enter the data on an Excel spreadsheet after the completion of the CRFs separately. Another independent researcher will compare the two datasets for check-up. If different data entry is discovered, data will be compared with the original CRFs to verify inconsistency. All modification will be marked on the CRFs. Research data will be gathered and saved, abiding by the Data Protection Act 1998. Paper files will be kept in a locked filing cabinet. Electronic documents will be stored in a password protected computer, with access restricted to the principal investigator. All research documents will be preserved for at least 5 years after publication.

Statistical analysis

Data analysis will be performed in a blinded pattern by statisticians of the Research Center of Clinical Epidemiology Affiliated to Peking University Third Hospital in China. Statistical analyses will be conducted on an intention-to-treat basis using the SPSS statistical package programme (V.18.0). Missing data will be replaced in

accordance with the principle of the last observation carried forward. A value of $p < 0.05$ will be considered statistically significant with a two-sided test. Baseline characteristics including gender, age and previous duration are described as n (%) for categorical data and $\text{mean} \pm \text{SD}$ for continuous data. To compare the differences among groups, we will perform analysis of variance for normally distributed data, the Kruskal-Wallis test for abnormally distributed data, and the χ^2 test for categorical data. Comparisons between two groups will be conducted using the Bonferroni method of post hoc multiple comparisons.

Ethical considerations

This study adheres to the principles of the Declaration of Helsinki and has been approved by the Research Ethical Committee of Beijing Hospital of TCM Affiliated to Capital Medical University (ref: 2013BL-094). We will conduct the research in the following hospitals: Beijing TCM Hospital Affiliated to Capital Medical University, Beijing Huguosi Hospital of TCM and China Rehabilitation Research Center. Each participant will sign written informed consents voluntarily.

DISCUSSION

Placebo or sham control is encouraged in clinical trials to avoid bias.⁵⁴ To our knowledge, no consensus has been established to recommend valid placebo or sham methods of moxibustion so far. Sham moxibustion is impractical for blinding purposes because of the common knowledge of moxibustion among Chinese patients. Owing to the preference for moxibustion, non-compliance of Chinese patients will make it difficult to use standard therapies as control treatment. For pragmatic purposes, we set a usual care group as a blank control group, rather than a certain effective therapy or a sham device.

In regard to the evaluation instruments, we selected a 72 h frequency–volume chart to record urination details, and I-QOL together with BI to assess quality of life. The frequency–volume chart and bladder diary is highly recommended in clinical trials by ICS.¹ Frequency–volume charts record the time and volume of each voiding, as well as the incontinence episodes. ICS suggested that frequency–volume charts should be recorded for at least 24 h.¹ A minimum of 72 h was required to ensure reliability for diary parameters.^{48 55–58} Thus, we will use a 72 h frequency–volume chart to alleviate burdens for patients and improve compliance.^{59 60}

As for the assessment of quality of life, I-QOL is strongly recommended to assess the effect of UI on patient quality of life.⁶¹ Previous research⁵¹ has affirmed the reliability and validity of I-QOL as an incontinence-related QOL instrument in neurogenic UI patients. The items of I-QOL focus on three dimensions, namely social embarrassment, avoidance behaviour, and psychosocial impact. BI is added to evaluate patients' activities of daily living, which is recognised as a valid and reliable outcome measurement for stroke survivors.⁵²

72-hour frequency-volume chart

Date	Time (a.m/p.m)	Volume voided (ml)	urinary incontinence (tick in the blank)	notes

Figure 4 72 h frequency–volume chart.

One limitation of this pilot study is that we will be unable to prevent therapists and participants from knowing the group allocation because of the characteristics of moxibustion. To minimise the bias, therapists will receive professional training and strict quality control. In order to homogenise the psychological effects, participants are informed that the effects of the two moxibustion techniques are uncertain. The words 'placebo' or 'control' will be avoided. Similar strategies have been applied in previous trials.^{62 63} Non-compliance of the control group is another limitation of this pilot trial. It may lead to a high dropout rate. Participants will be provided with 150 Renminbi (RMB) as financial compensation to improve compliance.

This study is the major sub-project focusing on stroke recovery, which is sponsored and funded by the National Administration of TCM of China. This protocol describes the first pilot randomised controlled trial evaluating the feasibility of conducting research to assess the efficacy and safety of ginger-salt-indirect moxibustion on UUI after stroke. Results of this preliminary study will provide essential information for the design of subsequent large scale trials. Further trials will focus on the assessment of urodynamic parameters and evaluation of efficacy and safety of moxibustion on UUI after stroke.

Acknowledgements We acknowledge State Administration of Traditional Chinese Medicine of China for agreeing to sponsor this study. The authors also would like to thank Ines Janowicz for the English language editing, and the reviewers for their helpful comments on this manuscript.

Contributors LPW and HLL conceived this study and prepared the initial protocol. LW drafted the manuscript and participated in the design of the study. GXS, YY, LZ, TZ participated in revising the protocol. LZ plans for the statistical analysis. LPW and HLL made amendments to the trial protocol. All authors read and approved the final manuscript.

Funding The trial is sponsored and funded by special project for the national clinical research bases construction of traditional Chinese medicine belonging to the State Administration of Traditional Chinese Medicine of the People's Republic of China, grant number: JD2X2012152.

Competing interests None.

Patient consent Obtained.

Ethics approval Research ethics approval was attained from the Research Ethical Committee of Beijing Hospital of Traditional Chinese Medicine Affiliated to Capital Medical University (ref: 2013BL-094).

Provenance and peer review Not commissioned; externally peer reviewed.

Data sharing statement The results of this pilot study will be disseminated via peer reviewed publications and conference presentations. All of the data are available.
