ABSTRACT

Objectives: The purpose of the study was to investigate the incidence of HIV and syphilis and their related factors, as well as to examine the predictors associated with seroconversion among migrant men who have sex with men (MSM) in Beijing, China.

Design: Prospective cohort study.

Setting: Beijing, China.

Participants: 511 HIV-negative migrant MSM.

Primary and secondary outcome measures:

Sociodemographic and behavioural information of participants, HIV and syphilis incidence rates, and factors associated with HIV/syphilis seroconversion and cohort retention.

Results: Of the 511 participants, 60.3% (308) and 52.4% (273) were retained at the 4- and 8-month follow-up visits, respectively. The HIV and syphilis incidence rates were 7.83 (95% CI 4.48 to 12.72) and 11.11 (95% CI 6.47 to 17.80) per 100 person-years, respectively. HIV seroconversion was significantly associated with 'had first anal intercourse at age 15 or younger' (adjusted HR (aHR) 9.20, 95% CI 1.94 to 43.56) and 'ever had group sex' (aHR 4.30, 95% CI 1.40 to 13.18). Bisexual orientation (aHR 5.09, 95% CI 1.02 to 25.57) was significantly associated with syphilis seroconversion. Predictors associated with both 4- and 8-month retention rates included age ≥ 25 years old and living in Beijing for more than 1 year.

Conclusions: The high incidence of HIV and syphilis among migrant MSM is a cause for concern.

A comprehensive strategy should be implemented to maintain a higher retention rate among migrant MSM.

INTRODUCTION

Over the last decade, sexual transmission has become the dominant route of HIV transmission in China.¹ The percentage of cases attributed to homosexual transmission rose from 7.3% in 2005 to 16.1% in 2011, comprising an increasing proportion of such infections among people living with HIV/AIDS

Strengths and limitations of this study

- This is the first cohort study to assess the incidence of HIV and syphilis among migrant men who have sex with men in Beijing.
- Cox regression analysis and stepwise multiple logistic regression were used to identify factors associated with HIV/syphilis seroconversion and cohort retention, respectively.
- Retention rates were relatively low, which means that the estimates of HIV/syphilis seroconversions may be biased because it is not known whether characteristics of the participants retained in the study were the same as those of the participants lost to follow-up.
- Sampling methods may have led to selection bias.
- None of the participants had migrated from Beijing, and the proportions of migrants to Beijing from different provinces varied, which may lead to difficulties with generalisation of the data.

(PLWHA).² The 2011 HIV epidemic assessment report stated that homosexual transmissions accounted for 17.4% of infections among the estimated 780 000 PLWHA, an increase from 14.7% in 2009.³ A growing number of studies have revealed an upward trend in HIV incidence among men who have sex with men (MSM) in different parts of China. For example, incidence rates per 100 person-years (PY) increased from 8.0 to 15.4 in 2006–2009 in Chongqing, from 5.0 to 6.3 in 2010–2012 in Zhejiang,⁴ from 1 to 10.2 in 2007–2009 in Liaoning, 5.7 to 8.2 in 2008–2011 in Jiangsu, and from 3.5

In recent years, there has been growing awareness that internal migration within China may be changing the distribution of the HIV epidemic by broadening social integration and connecting populations from different regions through sexual networks.¹

Data from national behavioural surveillance reports from 2004 to 2005 showed that in nine mainland provinces, migrant HIV/AIDS cases accounted for more than 50% of total infections.⁵ A number of cohort studies on MSM conducted in China have revealed an HIV epidemic among MSM, but in most of these studies MSM retention was not very high. Retention rates for these cohort studies were rarely over 70% at 12-month follow-up, with a few of them being below 20%.^{6–9} The reasons for these low rates may include the migration of MSM.⁸ Moreover, studies conducted among urban MSM also revealed a high proportion of migrants among MSM in major cities such as Beijing (88%),¹⁰ Chongqing (80.3%)¹¹ and Shanghai (79.7%).¹² Although migration itself does not spread HIV or other sexually transmitted diseases (STDs), it may increase the possibility of infection when combined with high-risk behaviours, which are prevalent among MSM. It has been confirmed in numerous studies that high-risk behaviours such as unprotected anal sex, commercial sex, group sex, casual sex and having multiple sexual partners are prevalent among MSM in China.^{13–15} On the other hand, the perceived stigma and discrimination resulting from traditional Chinese culture and conservative social values have increasingly led Chinese MSM to marry female sexual partners, which leads to a potential risk of transmitting HIV to the general population via heterosexual transmission.¹⁴ As migrants lack the stability of a family or a home community and are hampered by generally low educational levels, limited knowledge of HIV/AIDS prevention, and discrimination and marginalisation from the mainstream metropolitan society, they may engage more frequently in high-risk behaviours.^{16 17} Furthermore, due to China's household registration system and urban social security system, migrants have limited access to comprehensive, convenient and long-term health services.¹⁸ Recently, some cross-sectional studies in China demonstrated that compared to local MSM, migrant MSM engage in more high-risk sexual behaviours such as having multiple sexual partners, higher frequencies of anal and oral intercourse, and unprotected sexual behaviours with both males and females.^{15 19} As a marginal and vulnerable subpopulation, migrant MSM should be accorded a high level of consideration by researchers.

Beijing, the capital of China and a centre of political, economic and cultural activity, is a magnet for migrants. In 2012, Beijing's metropolitan population included some 7.7 million migrants, with migrants accounting for 37.4% of the total population of Beijing (China National Bureau of Statistics, 2013). According to statistics from the Beijing Municipal Bureau of Health, the proportion of MSM among those with HIV/AIDS increased from 22.8% in 2006 to 69.1% at the end of October 2013.²⁰ In addition, previous research among MSM in Beijing revealed that with the increasing epidemic of HIV among MSM in recent years, the number of migrants among recruited participants also showed a noticeable

upward trend.^{10 11} This phenomenon implies the following: (1) migrant MSM play a major role in MSM society in Beijing; (2) this marginal population has emerged gradually with the constant improvement in sampling methods; and (3) studies more targeted on the particular population are urgently needed, since currently only a few cross-sectional studies have been conducted to investigate HIV/STD infections and relative risk factors in this group.^{21 22} Thus, the purpose of this research was to assess the incidence of HIV and syphilis and examine the predictors associated with seroconversion and retention in a prospective cohort study among migrant MSM in Beijing, China.

METHODS

Study design and study population

This prospective cohort study was conducted in Beijing. Participants were all Chinese citizens and were recruited through three methods. First, study participants were recruited directly through website advertisements by a non-governmental AIDS volunteer group (<http://www.hivolunt.net>). Second, peer recruiters were hired and trained to distribute flyers with study-related information at MSM-frequented venues (eg, MSM clubs, bars, parks and bathhouses). Third, study participants were encouraged to refer their peers for enrolment in the study. Once a potential participant had been referred or identified, local research team members approached the individual to verify eligibility, which included age ≥ 18 years, male gender, HIV-negative, had sex with another male in the past 12 months, lacked permanent household registration in Beijing and provided written informed consent.

We calculated the sample size using the equation

$$n = \frac{(z_{\alpha} \sqrt{2pq} + z_{\beta} \sqrt{p_0q_0 + p_1q_1})^2}{(p_1 - p_0)^2},$$

where α and β are 0.05 and 0.10 and the corresponding z_{α} and z_{β} are 1.96 and 1.282. p_0 represents the prevalence of HIV among general MSM in Beijing, which was set at 0.02 according to the estimates of the HIV epidemic in 2012–2013 in Beijing; p_1 represents the HIV prevalence among migrant MSM in Beijing, which was estimated to be higher than p_0 at 0.06, so n was calculated to be 502. In case of loss to follow-up, we increased the target sample size by 10%. A total of 547 participants were screened during the baseline screening survey from September to October 2009, of whom 36 were HIV-positive and 162 were syphilis-positive. In light of the curability and reinfection potential of syphilis, participants who were syphilis-positive at baseline were still recruited into the cohort. Thus, a total of 511 eligible and consenting MSM were enrolled into the prospective cohort, of whom 141 were syphilis-positive. Participants were followed up for 4 and 8 months after the baseline survey. At each study visit (baseline, 4-month follow-up

and 8-month follow-up), eligible participants were interviewed by trained health professionals in a private room of the study clinic, and blood plasma specimens were collected and analysed for HIV and syphilis antibodies by experienced physicians. One week later, each participant received their test results anonymously through the use of a private identification code. All participants who tested positive for HIV/syphilis received additional post-test counselling and referrals to relevant free services. Every participant received 50 RMB (US\$7.4), 12 free condoms and one free lubricant after each completed study visit. Every participant was asked to provide at least two different and current methods of contact, and reminder calls were made before the follow-up day to verify that the exact time of the visit was convenient for them. The study protocol and informed consent forms were approved by the Institutional Review Boards of the National Center for AIDS/STD Control and Prevention of the China Center for Disease Control and Prevention (figure 1).

Data collection and laboratory tests

Questionnaire-based interviews were conducted on a one-on-one basis in a separate private room of the

district clinic. Data on demographics, sexual behaviour and history of STDs were collected. Participants' questionnaires and blood specimens were linked through the assignment of a unique identifier code in the follow-up visits.

Blood specimens were tested for HIV and syphilis infection. HIV infection status was determined by ELISA (InTec Products, Xiamen, China) screening and confirmed by an HIV-1/2 Western blot (HIV Blot 2.2 WBTM, Genelabs Diagnostics, Singapore). Syphilis infection was determined by a rapid plasma reagin test (Shanghai Rongsheng, Shanghai, China) and confirmed using a *Treponema pallidum* particle agglutination assay (TPPA) test (Fujirebio, Tokyo, Japan).

Statistical analysis

Questionnaire data were double-entered and then checked for accuracy using EpiData software (V.3.1; The EpiData Association, Odense, Denmark). Data were analysed using Stata/SE (V.12.0 for Windows; StataCorp LP, College Station, USA). HIV seroconversion was estimated to have occurred at the midpoint between the time of the baseline HIV test and the time of the follow-up HIV test with a seropositive result. Syphilis

Figure 1 Study flowchart of the migrant men who have sex with men (MSM) cohort, with a focus on HIV and syphilis incidence.

seroconversion was estimated to have occurred at the halfway point between the previous visit and the visit where seroconversion occurred. HIV/syphilis incidence density was calculated based on a Poisson distribution, with number of seroconversion incidents within the follow-up period as the numerator and PY over the entire follow-up period as the denominator. Categorical factors associated with retention rate were analysed by univariate logistic regression, including baseline demographic and behavioural characteristics. A stepwise multiple logistic regression (out 0.05, in 0.02) was used to select independent factors for the retention rate. A Cox regression model was used in univariate and multiple regression analyses to identify correlates of time to HIV seroconversion. Statistically significant variables in univariate analysis ($p < 0.10$) were entered simultaneously into a multivariate Cox proportional hazard regression model to determine the adjusted HR (aHR) for HIV/syphilis seroconversion-related risk factors.

RESULTS

Baseline characteristics of the participants

The median age of the 511 participants was 29 years, 94.32% belonged to the Han ethnic group, 64.77% were single, 22.90% were married or cohabiting, and 12.33% were separated, divorced or widowed. As regards educational level, 73.19% had received a high school education or lower. About half (54.01%) had monthly incomes of <US\$300. Participants who identified themselves as exclusively homosexual or as bisexual accounted for 60.67% and 37.57% of the MSM, respectively. Overall, 16.05% and 44.03% of the participants thought it was impossible or improbable, respectively, that they would be infected with HIV. The median age of sexual debut was 20 years, and 58.71% experienced their sexual debut with a male. The median age of first anal intercourse was 22, and 58.65% of participants did not use a condom at first anal intercourse. In the past year, 78.67% of the participants had ever received condoms, 65.17% had ever received lubricant, 23.68% had ever taken part in peer education, 18.40% had ever undergone examination or treatment for STDs and 52.49% had ever received voluntary counselling and testing services (VCTs).

As regards behaviours in the past 6 months among participants, the median number of male sex partners was three. Concerning high-risk behaviours, 327 (63.99%) had oral sex with male sex partners, of whom 22 (6.73%) consistently used a condom with regular sex partners, and 26 (7.95%) with casual partners. All 511 (100%) had anal sex with male sex partners, of whom 13.11% had consistently used a condom with regular sex partners, and 66 (18.70%) with casual partners. A total of 61 (11.94%) participants had ever engaged in commercial sexual behaviour, among whom 35 (57.38%) had paid for sex and 43 (70.49%) had received money for sex. A total of 59 (11.55%) had ever engaged in

group sex, which happened almost exclusively (96.61%) among males. A total of 166 (32.49%) had ever engaged in sex under the influence of alcohol, among whom 152 (92.77%) had homosexual intercourse while intoxicated (table 1).

Incidence of HIV infection, syphilis infection, HIV–syphilis co-infection, and factors predicting HIV and syphilis seroconversion

During the 8-month follow-up, 16 HIV seroconversions were observed over 204.27 PY of observation, resulting in an incidence rate of 7.83 per 100 PY (95% CI 4.48 to 12.72). At the 4-month visit, the HIV incidence rate was 8.33 per 100 PY (95% CI 3.81 to 15.81), while at the 8-month visit it was 3.83 per 100 PY (95% CI 1.54 to 7.89). During the 8-month follow-up period, the syphilis incidence rate was 11.11 per 100 PY (95% CI 6.47 to 17.80). At the 4- and 8-month visits, the syphilis incidence rates were 10.03 per 100 PY (95% CI 4.33 to 19.76) and 15.25 per 100 PY (95% CI 6.97 to 28.94), respectively. Six HIV seroconversion cases were observed, becoming syphilis-positive over 52.10 PY, resulting in an incidence of co-infection of 11.52 per 100 PY (95% CI 4.23 to 25.07).

Multivariate Cox regression analysis indicated that age ≤ 15 years at first anal intercourse (aHR 9.20, 95% CI 1.94 to 43.56, $p = 0.050$) and ever had group sex (aHR 4.30, 95% CI 1.40 to 13.18, $p = 0.011$) were significantly associated with time to HIV seroconversion (table 2). Bisexual orientation (aHR 5.09, 95% CI 1.02 to 25.57, $p = 0.048$) and had more than one sex partners since last investigation (aHR 9.22, 95% CI 1.13 to 73.37, $p = 0.038$) were significantly identified as risk factors for syphilis incidence (table 3).

Predictors of cohort retention

Of the 511 participants, 60.3% (308) were retained in the cohort at the 4-month follow-up and 54.6% (274) were retained at the 8-month follow-up.

Univariate factors among baseline characteristics which were significantly associated with 4-month retention were analysed with stepwise multiple logistic regression. Four factors were kept in the final model: age > 25 years (adjusted OR (aOR) 1.81, 95% CI 1.07 to 3.06, $p = 0.026$), living in Beijing for more than 1 year (aOR 3.68, 95% CI 2.04 to 6.64, $p < 0.001$), had at least one female sex partner since last investigation (aOR 0.48, 95% CI 0.29 to 0.80, $p = 0.005$), and had ever received VCTs in the past 12 months (aOR 1.71, 95% CI 1.07 to 2.72, $p < 0.024$) (table 4).

For 8-month retention, age > 25 years (aOR 1.76, 95% CI 1.16 to 2.68, $p = 0.008$), living in Beijing for more than 1 year (aOR 1.68, 95% CI 1.03 to 2.73, $p = 0.039$), first sexual partner was female (aOR 0.60, 95% CI 0.41 to 0.88, $p = 0.009$), ever had group sex (aOR 0.50, 95% CI 0.28 to 0.89, $p = 0.019$), and had received lubricant in the past 12 months (aOR 2.31, 95% CI 1.56 to 3.42,

DISCUSSION

Our study found that the prevalence of HIV (6.58%) among migrant MSM was at epidemic levels, which was remarkable when compared to that of a previous study among the general migrant population (0%) in Beijing.²³ Additionally, it was higher than the 4.8% in 2007 among general MSM in Beijing.²⁴ A similar result (5.9%) was found in a recent cross-sectional study among migrant MSM.²³ Incidence in this subgroup (7.83/100 PY) was consistent with that of migrant MSM (8.51/100 PY) in an MSM cohort study in Beijing, and higher than the incidence among permanent resident MSM.²⁵ It was also higher than the incidence of general MSM in different parts of China.^{6 7}

The study found that participants whose first anal intercourse occurred before age 15 had significantly higher risk for HIV seroconversion. An American study of young minority MSM found that study participants who had an MSM sexual debut before 16 years of age were more likely to have psychological problems and high-risk behaviours like exchanging sex and drug use.²⁶ Early sexual debut could have a deep and long-term influence on individuals' attitudes towards sex, but appropriate sex education has generally been shunned in traditional Chinese education. Our study indicated that early sex education should be adapted to and take account of Chinese tradition, and that relevant measures need to be implemented as soon as possible. Another risk factor significantly associated with HIV incidence was ever had group sex. An explanation of this observation is that psychological stress caused by stigma and discrimination hinders the development of longer term

MSM, men who have sex with men; PY, person-years.

relationships between MSM,²⁷ and having sex with multiple partners increases the chance of HIV transmission. This indicates a need for confidentiality and supportive services for migrant MSM. Serious attention should also be paid to the prevalence of STDs. The prevalence of syphilis (29.62%) was higher than in previous studies conducted among MSM in Beijing, which found a prevalence of 19.8% in 2007²⁴ and 22.0% in 2009.¹⁰ The incidence of syphilis (11.11/100 PY) was also extremely high

compared to the rate of 8.06/100 PY reported in a cohort study among MSM during the same period in 2009.²⁵ A high prevalence of syphilis among MSM is a common risk factor for HIV infection because of the biological and behavioural links between syphilis and HIV.²⁸

The multiple regression analysis significantly revealed that self-identified bisexuals were five times more likely than homosexuals to be infected with syphilis. One

MSM, men who have sex with men.

major reason for this finding could be that MSM who had had sex with females may have more varied sexual behaviours with a wider range of sexual partners, including males and females. In addition, a cross-sectional study among young migrant MSM in Beijing revealed that MSM who were engaged in bisexual behaviour had a higher rate of unprotected sex with stable female partners and were less likely to take part in preventive behaviours,¹⁸ which was consistent with our finding that those who had at least one female sex partner and those whose first sexual partner was female were significantly more likely to be lost at the 4- and 8-month follow-up visits, respectively. MSM face strong social pressure and stigma in China, which may lead them to hide their sexual orientation by unwillingly engaging in heterosexual relationships; thus, many Chinese MSM will potentially enter a heterosexual marriage due to social and familial pressure.⁴ Concerned about disclosing their MSM behaviour to their female partners, bisexual MSM may be more reluctant to be followed up. Also, MSM with female partners are more likely to be engaged in risk behaviours, such as having unprotected sex to demonstrate loyalty to their female partners and having commercial or casual sex with men. Moreover, only 18.4% of the participants reported having undergone an examination or treatment for STDs in the past 12 months, which may be related to the high cost of health services and low coverage of health insurance for the migrant population.¹⁸ Low risk-awareness might be another reason for their lower access to HIV/STD testing and treatment. All of these factors emphasise the urgent need for widespread and accurate syphilis screening and affordable treatment for migrant MSM in Beijing.

In our study, the retention rate was lower than in previous cohort studies conducted among general MSM in Beijing (86.2% in 2007, 86.8% in 2009).^{25–26} The multiple regression analysis showed that participants who

were less than 25 years old were more likely to be lost at both the 4- and 8-month follow-up visits. Similar problems have occurred among studies of young MSM in the USA.²⁹ A plausible reason for this finding was that many young people in China have poor knowledge of safe sexual behaviours. Traditional interventions are more pragmatic but less attractive and appropriate for young people. A qualitative investigation conducted among young MSM in Milwaukee and Detroit in the USA offered some new approaches, such as integrating HIV/AIDS care intervention into the daily lives of participants and helping solve social relationship problems.³⁰ However, as young Chinese MSM most likely differ from Americans in some aspects, intervention measures among young MSM in Beijing deserve further investigation.

Regarding positive predictors, we found those who had been in Beijing for more than 1 year or who had received lubricant were more likely to be retained in this cohort at both the 4- and 8-month follow-up visits. A similar result was found in Yangzhou.⁸ Migrant MSM who stay longer in Beijing may have more chances to receive effective and stable intervention services, and consequent increasing awareness of self-protection might encourage them to pay closer attention to advances in research. As a result, migrants may be more likely to remain in the study to demonstrate their support. However, the data revealed that receiving VCT services in the past 12 months was a positive factor at the 4-month follow-up visit, which was replaced by receiving lubricant at the 8-month visit. This indicates that factors associated with retention may change as time goes on, which implies that we should adjust intervention methods over time so as to keep the entire cohort more stable. The results of our study showed that the provision of interventions for this population was limited. A specific intervention strategy targeted at migrant MSM and

the mobility problem inherent to migrant populations is urgently needed.

This study has a number of limitations. First, retention rates were relatively low, which means that the estimates of HIV/syphilis seroconversion may be biased because we do not know whether the characteristics of the participants retained in the study were the same as those of the participants lost to follow-up. Second, the use of non-random sampling methods may have led to selection bias. Third, the sample size was insufficient, and some potentially relevant factors may be concealed by the small sample size. Last, the study subjects were all immigrants to and not emigrants from Beijing, and the proportion of migrants from different provinces varied. There is no evidence to show the data could be generalised to other regions.

To our knowledge, this is the first cohort study to assess the incidence of HIV and syphilis among migrant MSM in Beijing. With extremely prevalent risk behaviours, the migrant MSM had a high level of HIV incidence, and a serious epidemic of syphilis was found among this subgroup. Bisexual MSM were at a high risk of syphilis seroconversion but were less visible among migrant MSM. Future prevention efforts should include screening and appropriate treatment for syphilis. Different types of intervention services need to be implemented for this marginalised group. To improve the health of bisexual MSM and that of their partners, more attention should be paid to the female partners of bisexual MSM to encourage them to undergo testing and follow up. Risk behaviours and the HIV/STD epidemic among migrant MSM need to be investigated in the future to facilitate greater understanding.
