ABSTRACT

Introduction For ill children as well as for their parents and siblings, childhood cancer poses a major challenge. Little is known about the reintegration into daily life of childhood cancer survivors and their families. The aim of this prospective observational study is to further the understanding of the role of rehabilitation measures in the reintegration process of childhood leukaemia or brain tumour survivors and their family members after the end of cancer treatment.

Methods and analysis This prospective observational study consists of three study arms: a quantitative study in cooperation with three German paediatric oncological study registries (study arm 1), a quantitative study in cooperation with a rehabilitation clinic that offers a family-oriented paediatric oncological rehabilitation programme (study arm 2) and a qualitative study at 12-month follow-up including families from the study arms 1 and 2 (study arm 3). In study arm 1, children, parents and siblings are surveyed after treatment (baseline), 4–6 months after baseline measurement and at 12-month follow-up. In study arm 2, data are collected at the beginning and at the end of the rehabilitation measure and at 12-month follow-up. Families are assessed with standardised questionnaires on quality of life, emotional and behavioural symptoms, depression, anxiety, fear of progression, coping and family functioning. Furthermore, self-developed items on rehabilitation aims and reintegration into daily life are used. Where applicable, users and non-users of rehabilitation measures will be compared regarding the outcome parameters. Longitudinal data will be analysed by means of multivariate analysis strategies. Reference values will be used for comparisons if applicable. Qualitative data will be analysed using thematic analysis.

Ethics and dissemination This study has been approved by the medical ethics committee of the Medical Chamber of Hamburg. Data will be published in peer-reviewed journals and presented at conferences.

INTRODUCTION

Cancer diagnosis in children and adolescents leads to major disruption in their own lives and in the whole family. Depending

Strengths and limitations of this study

- The study includes users and non-users of a family-oriented rehabilitation programme and thus enables the investigation of facilitating factors and barriers for the utilisation of rehabilitation measures as well as its role in long-term reintegration processes.
- The inclusion of childhood cancer survivors, their parents and siblings allows for multiperspective analyses on long-term developments and factors influencing the families' reintegration into daily life after childhood cancer.
- The results of this study may help to identify specific needs for support after the end of cancer treatment and to optimise healthcare services that support the families with the re-entry into 'normal' life.
- Due to the mainly questionnaire-based study design and thus the required sufficient German language skills, a selection bias cannot be ruled out.
- Ethical guidelines and the effort to carry out a nationwide study require a complex recruitment scheme in which a subsequent non-responder analysis can only be conducted for medical data.

on diagnosis and treatment, children and adolescents are torn out of their daily life such as family and social life as well as school for months or even for years. Children and adolescents with cancer suffer from physical changes and display impaired quality of life and well-being compared with their healthy peers.^{1–3} Behavioural changes and difficulties in reintegrating in school can occur in consequence of cancer disease and treatment.⁴ Even after the end of cancer treatment, patients with childhood cancer show elevated emotional distress and have an increased risk for developing mental health problems.^{5,6} Likewise, parents and siblings of the patient are confronted with major changes and burden in their lives when a child is diagnosed with cancer.^{7,8} In addition to the

life-threatening disease, separation of family members due to hospital stays, social isolation or financial difficulties impact families.⁹ Parents of patients with childhood cancer report post-traumatic stress and low quality of life.^{10 11} They experience fear of progression and are highly emotionally burdened.^{12 13} Healthy siblings often experience the loss of parental attention and have to fulfil new responsibilities and roles within the family.¹⁴ They show emotional reactions such as elevated distress and anxiety levels as well as behavioural problems or difficulties in school.¹⁵

The most frequent cancer diagnoses in children under the age of 18 years in Germany are leukaemia and brain tumours.¹⁶ Due to improved treatment methods, the 5-year survival rate in Germany has increased to approximately 80% for patients with childhood cancer under the age of 15 years.¹⁶ However, patients with childhood cancer and their families are at risk for long-term consequences. In this study, the end of cancer treatment is defined as the end of intensive cancer treatments such as chemotherapy, radiation, surgery and stem cell transplantation or bone marrow transplantation. After the end of cancer treatment, patients and their families are discharged from structured treatment plans to a new daily life — a milestone for many families. They want to look forward and try to restore family life to normality as before the disease.¹⁷ While they are relieved surviving the disease, families describe returning to daily life as a difficult time.¹⁸ In particular, parents can experience feelings of exhaustion and inner emptiness after a long time of exceptional circumstances requiring them to function and to pull through.¹⁷ After a long period of absence from school for the children and from working life for the parents, re-entry and reintegration are the next steps after the end of cancer treatment.^{19 20} Still, familial conflicts can impede scholastic reintegration.²¹

In the German rehabilitation system, two rehabilitation concepts are established to support patients with childhood cancer and their families after the inpatient cancer treatment.^{22 23} Family-oriented rehabilitation was developed for patients with childhood cancer (≤ 15 years), their parents and healthy siblings.²² The primary aim of the 4-week inpatient rehabilitation programme is to achieve the patients' rehabilitation goals and to ensure the treatment success.²² Therefore, multiprofessional therapeutic teams of physicians, clinical psychologists, social education workers and other professionals offer group or individual therapies and activities as required for all family members during the rehabilitation programme.²² For adolescent patients with cancer (>15 years), a rehabilitation programme in small groups was developed to adapt to the specific developmental needs of adolescents (e.g. support with development of autonomy).²² In this rehabilitation programme, adolescents are not accompanied by their family members.

So far, only a few studies evaluated family-oriented rehabilitation programmes. Overall, a positive impact on quality of life and psychological symptoms in patients,

siblings and parents could be found.^{3 24–28} In a recent study, a different evaluation approach has been pursued. The authors analysed 422 medical discharge summaries of children and adolescents who participated in a paediatric oncological rehabilitation measure.²⁹ According to rehabilitation physicians' opinion, 86% of the children and adolescents achieved their rehabilitation goals such as the improvement of physical efficiency and peer group integration. However, until now there are no longitudinal studies with an adequate reference group, and previous studies focused primarily on aspects such as quality of life.^{24 26 28} Thereby, parental fear of progression or family functioning have not been investigated in the context of family-oriented rehabilitation programmes. Furthermore, in Germany, there is no systematic data available on the participation rate in family-oriented paediatric cancer rehabilitation programmes. Expert ratings range from 30% to 100% (unpublished pilot data). Moreover, little is known about the reintegration of childhood cancer survivors and their families into daily life after the end of cancer treatment and the potential role of rehabilitation measures in the reintegration process. Therefore, the primary aim of this study is to further the understanding of the process of reintegration of paediatric cancer survivors and their family members after the end of cancer treatment and the role of rehabilitation measures in this process.

The main research questions are:

1. Reintegration: which factors impede or facilitate reintegration?
2. Use of rehabilitation measures: which factors impede or facilitate use of rehabilitation measures?
3. Rehabilitation process: which factors influence activity and participation of families during and after the rehabilitation measure?
4. Rehabilitation process: which treatments do patients and families receive during the rehabilitation measure and how are rehabilitation goals, treatments and goal attainment associated?
5. Effects of rehabilitation measures: which are the long-term effects of rehabilitation measures with regard to reintegration and psychosocial outcomes?

METHODS AND ANALYSIS

Design

In order to address the research questions with regard to the role of rehabilitation measures in the reintegration of children and their families after completion of cancer treatment mentioned above, we conduct a prospective observational study with a longitudinal design including a baseline measurement and two follow-up measurements. The study focuses on the most frequent childhood cancers in Germany¹⁶ and thus includes children with brain tumours or leukaemia and their families.

The investigation of factors associated with the use of rehabilitation measures and the role of rehabilitation measures for the reintegration after the end of cancer

treatment requires the inclusion of a comparison group of non-users. Therefore, this study aims to include a consecutive sample of patients and families at the end of cancer treatment in order to include both subsequent users and non-users of rehabilitation measures.

The study will consist of three study arms:

- ▶ The first study arm is conducted as a quantitative study in cooperation with three nationwide German paediatric oncological study registries in which childhood cancer patients with high and low grade brain tumours as well as leukaemia are registered (main research focus: participation vs non-participation in rehabilitation measures).
- ▶ The second study arm is a quantitative study in cooperation with a rehabilitation clinic offering a family-oriented paediatric cancer rehabilitation programme (main research focus: rehabilitation process).
- ▶ The third study arm is a qualitative interview study including 20–25 families from study arms 1 and 2 (main research focus: deeper understanding of the reintegration processes).

Measurement time points

Study arm 1 (study registries)

- ▶ Baseline: end of cancer treatment
- ▶ Follow-up: 4–6 months after baseline survey
- ▶ 12-month follow-up: 12 months after first follow-up

Study arm 2 (rehabilitation clinic)

- ▶ Pre: beginning of the rehabilitation measure
- ▶ Post: end of the rehabilitation measure
- ▶ 12-month follow-up: 12 months after the end of the rehabilitation measure

Study arm 3 (qualitative study)

- ▶ Twelve-month follow-up

The different measurement time points in study arms 1 and 2 have been chosen for two reasons. First, the timing of the entry into a rehabilitation measure depends on the families and their specific situation. Consequently, we cannot survey families after the end of cancer treatment in study arm 2. Second, the follow-up measurement in study arm 1 is temporally delayed in comparison with the post measurement in study arm 2 because we want to give the families the chance to use a rehabilitation measure between the first two measurement time points in order to receive matching times of measurements for the last two measurements in both study arms.

Participants from study arm 1 who attend the rehabilitation measure in the cooperating rehabilitation clinic drop out of study arm 1 and subsequently are surveyed in study arm 2. An overview of the recruitment and procedure in the study arms 1 and 2 is displayed in [figure 1](#).

Cooperation partners

The recruitment of participants in study arm 1 is carried out in cooperation with the *International HIT-MED Registry*

(I-HIT-MED; University Medical Center Hamburg-Eppendorf; ClinicalTrials.gov Identifier: NCT02417324), the study registry of the *SIOP-LGG 2004 study* (SIOP-LGG; Medical Center Augsburg; ClinicalTrials.gov Identifier: NCT00276640) and the *CoALL-study registry* (CoALL; University Medical Center Hamburg-Eppendorf; ClinicalTrials.gov Identifier: NCT01228331). The treatment group in study arm 2 is recruited in the Rehabilitation Clinic Bad Oexen.

Inclusion and exclusion criteria

In study arms 1 and 2, children and adolescents (≥ 11 years) and their siblings (≥ 11 years) as well as their parents are surveyed. Parents can be biological or social parents or other attachment figures. In study arm 1, inclusion and exclusion criteria will be assessed by the study registries (age and diagnosis) and the healthcare providers in the clinics. The rehabilitation physicians will assess inclusion and exclusion criteria at the beginning of the rehabilitation measure in study arm 2.

Inclusion criteria

- ▶ Brain tumour or leukaemia diagnosis (patients with low grade brain tumours and their families are only included if the patient received radiation or chemotherapy)
- ▶ Patients' age under 18 years
- ▶ Signed informed consent

Exclusion criteria

- ▶ Different diagnosis than brain tumour or leukaemia
- ▶ Patients' age over 17 years
- ▶ Refusal of participation
- ▶ Physical and/or mental burden
- ▶ Cognitive limitations
- ▶ Insufficient language skills

Recruitment and procedure

Study arm 1

The study registries estimate the end of cancer treatment of their registered patients based on the information available (i.e. time of diagnosis, treatment protocol). They inform the clinic where the patient receives treatment about the study. Healthcare providers at the clinics inform the patients and their families about the study after the end of cancer treatment, ask them to participate and pass a data set containing an invitation and information letter as well as a consent form to contact the family. After patients or parents send the signed consent and their contact data to the Department of Medical Psychology (University Medical Center Hamburg-Eppendorf), the parents are sent a set of baseline questionnaires and consent forms for participation for all included family members. If the signed informed consent form to contact the families is not sent back within 4 weeks after contacting the clinic where the patient receives treatment, the study registries remind the healthcare providers in the clinics to contact or remind the families where necessary.

Figure 1. Study recruitment and procedure in study arms 1 and 2

Figure 1 Study recruitment and procedure in study arms 1 and 2.

Study arm 2

The rehabilitation clinic identifies patients with brain tumour or leukaemia at the beginning of the rehabilitation measure, informs them and their families about the study and asks them to participate. If the families agree to participate and sign the informed consent form, they receive a baseline questionnaire for all family members applicable according to the inclusion criteria. At the end of the rehabilitation measure, the families receive the second set of questionnaires. After 12 months, they receive the final set of questionnaires from the rehabilitation clinic.

If families agree to participate but have already been recruited into study arm 1, the rehabilitation clinic informs the principal investigator and the family drops out of study arm 1.

Study arm 3

During the quantitative survey period patients from study arms 1 and 2 and their families are informed about the qualitative study. We conduct a consecutive sampling of the first 20–25 families that agree to participate in the interview study. We include multiple family members if both parents agree to participate. However, single parents or families with only one interested parent will also be included. If parents agree to be interviewed about 12–18 months after baseline measurement, they give their informed consent and contact data, where they can be reached via telephone. About 12–18 months after baseline measurement, one of the researchers is going to contact them and to conduct the telephone interview.

Outcomes and measurements

Study arms 1 and 2

Quality of life

Children

Children's health-related quality of life is assessed by the KINDL-R.³⁰ There are three self-assessment versions (4–6 years, 7–13 years and 14–17 years) and two proxy versions for parents (3–6 years and 7–17 years).³¹ In this study, we use the self-assessment version for 14–17-year-olds and the proxy version for parents of 7–17-year-olds. In an unpublished feasibility study, the version for 14–17-year-olds has also been used for children from 11 to 17 years of age without any difficulties. The KINDL-R includes 24 items covering six dimensions of quality of life (physical well-being, psychological well-being, self-esteem, family, friends and school) and six additional items on the dimension illness.³² Items refer to the past week and can be rated on a 5-point Likert scale from (1) never to (5) always. A total score and seven subscale scores can be calculated. The self-assessment version and the proxy version both have proved to be reliable and valid.³³

Parents

The Ulm Quality of Life Inventory for Parents (ULQIE) is a 29-item self-report instrument, designed for measuring the quality of life of parents of chronically ill children

on five subscales: functioning, satisfaction with family situation, emotional stress, self-fulfilment and general well-being.³⁴ Parents assess on a 5-point Likert scale from (0) never to (4) always their quality of life over the past week. High values indicate a high quality of life.³⁴ A total score of quality of life in general and five subscale scores can be obtained. The ULQIE has satisfactory psychometric properties.³⁴

Emotional and behavioural symptoms

Children

The Strengths and Difficulties Questionnaire is a 25-item instrument to assess strengths and difficulties in behaviour of children and adolescents on five different subscales: emotional symptoms, conduct problems, hyperactivity-inattention, peer relationship problems and prosocial behaviour.³⁵ There are two versions: a self-report version for 11–16-year-olds and a version for parents and teachers of 4–16-year-olds.³⁵ Both versions use a 3-point Likert scale with (0) not true, (1) somewhat true and (2) certainly true. A total difficulties score as well as five subscale scores can be calculated. In this study, both versions are used to obtain a multiperspective view on the behaviour of patients with paediatric cancer and their siblings. The self-report version and the version for parents both have adequate psychometric properties.^{35 36}

Depression

Parents

The 9-item depression module (PHQ-9) of the Patient Health Questionnaire (PHQ) is a self-report depression screening questionnaire.³⁷ The PHQ-9 is used to classify depression severity in parents. The items reflect depression criteria based on the diagnosis criteria for depression disorders of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV).³⁸ Answers can be given in four categories from (0) not at all to (3) nearly every day.³⁹ The total score can be interpreted as the level of depression severity with cut-off values indicating minimal, mild, moderate, moderately severe and severe depression.³⁹ The PHQ-9 has proved to be a valid and reliable questionnaire.^{39 40}

Anxiety

Parents

The Generalized Anxiety Disorder Screener (GAD-7) is a valid and reliable 7-item self-report instrument designed to identify probable cases of generalised anxiety disorder.^{41 42} In this study, the GAD-7 is used to classify symptoms of anxiety in parents. On a 4-point Likert scale from (0) not at all to (3) nearly every day subjects report how often they have been bothered by seven symptoms of the generalised anxiety disorder, derived from the DSM-IV diagnostic criteria A, B and C.^{38 42} By using cut-off values the subjects total GAD-7 score can be classified in mild, moderate and severe anxiety symptom levels.⁴¹

Fear of progression

Parents

To measure fear of progression in parents of patients with paediatric cancer, the adaption of the Fear of Progression Questionnaire for the parental perspective (FoP-Q-SF/PR) is used in this study.⁴³ The questionnaire contains nine items. Each of the items is scored on a 5-point Likert scale from (1) never to (5) very often. A total score can be calculated⁴⁴ and a recommended cut-off value can be used for interpretation.⁴³ The FoP-Q-SF/PR has adequate psychometric properties.⁴³

Coping

Children

Coping in patients with paediatric cancer and their siblings is measured by the KIDCOPE,⁴⁵ which assesses 10 different coping strategies: distraction, social withdrawal, wishful thinking, self-criticism, blaming others, problem solving, emotional regulation, cognitive restructuring, social support and resignation. There are two versions of the KIDCOPE: a 15-item version for children (7–12.9 years) and a 11-item version for adolescents (13–18.9 years).⁴⁵ In this study, we use the version for adolescents. Children rate the frequency of the coping strategy use on a 4-point Likert scale and the efficacy of each particular strategy on a 5-point Likert scale.⁴⁵ The KIDCOPE has a sufficient reliability and validity.^{45 46}

Parents

Coping in parents is measured by the Coping Health Inventory for Parents (CHIP).⁴⁷ The CHIP is used to assess the efficacy of different coping strategies in parents.⁴⁷ The 45 items are covering three different coping patterns: family (maintaining family integration, cooperation and an optimistic definition of the situation), support (maintaining social support, self-esteem and psychological stability) and medical (understanding the medical situation through communication with other parents and consultation with the medical staff).⁴⁸ Ratings are made on a 4-point Likert scale from (0) not helpful to (3) extremely helpful. If parents did not use a certain coping strategy, they can specify if they did not use it or if they could not use it.⁴⁷ A total score as well as subscale scores can be calculated. Higher scores indicate more helpful coping strategies. The reliability and validity of the CHIP have been proved.⁴⁸

Family functioning

Parents and children assess the global family functioning on the general functioning subscale of the McMaster Family Assessment Device (FAD-GF).⁴⁹ The subscale is composed of 12 items with a 4-point Likert scale from (1) strongly agree to (4) strongly disagree including aspects such as acceptance in the family and problem-solving behaviour. Higher total scores indicate lower family functioning.⁴⁹ The FAD-GF has proved to be reliable and valid.⁵⁰

Additional measures

In addition to the validated scales listed above, we use self-developed items to assess parental burden related to the cancer illness, rehabilitation goals and their attainment, patient satisfaction or participant satisfaction respectively, reintegration and healthcare use. The self-developed items have been evaluated in an unpublished feasibility study. Received treatments during the rehabilitation measure and recommendations for after-care are extracted from the medical discharge records in study arm 2. An overview of instruments, assessments and measurement time points (study arms 1 and 2) is displayed in [table 1](#).

Study arm 3

The interviews will be conducted using an interview guideline developed on basis of theoretical background and knowledge from prior studies on similar topics. To test the comprehensibility of the questions, a pilot interview will be conducted. The interview guideline will cover the following aspects:

- ▶ How did the process of reintegration in school (for children) and working life (for parents) proceed?
- ▶ What are the experiences regarding facilitating factors and barriers for reintegration?
- ▶ If using rehabilitation measure: which factors were helpful for reintegration? Which aspects were amiss?
- ▶ Which healthcare services did parents and children use after completion of treatment?

Data analyses

Quantitative analyses

The research questions on reintegration, use of rehabilitation measures and the effects of rehabilitation measures (research questions 1, 2 and 5) will be analysed based on data from the combined sample from study arms 1 and 2. Where applicable, the sample will be divided into users and non-users of rehabilitation measures.

The research questions on the rehabilitation process (research questions 3 and 4) are analysed based on data from study arm 2 only.

Baseline scores and follow-up scores are analysed using descriptive analyses and if applicable compared with reference values. Using univariate analyses (t-test, analysis of variance) or comparable non-parametric tests, differences between subgroups (e.g. mothers and fathers, cancer patients and siblings, users and non-users of rehabilitation measures, patients with leukaemia and brain tumour) will be explored. Correlations will be calculated to explore associations between outcome variables and to measure potential non-independence of data in families.

The longitudinal nature of this study allows multivariate analysis strategies such as regression analysis, multilevel modelling and repeated measure analysis of variance to investigate the role of other factors and to examine changes over time.

*Only in study arm 2.

†From study registries (study arm 1) or rehabilitation physician (study arm 2).

‡Assessed by rehabilitation physician (study arm 2).

FAD-GF, Family Assessment Device (General Functioning Scale; FoP-Q-SF/PR, Fear of Progression Questionnaire.

Qualitative analyses

Qualitative interviews (study arm 3) will be recorded and transcribed verbatim. Transcripts will be analysed using thematic analysis.^{51 52} Main themes discussed in the interviews will be extracted in a first step. These themes will be subcategorised and discussed. A coding guideline with exemplary codes will be developed and presents the basis for a final coding of the entire material. To verify reliability and validity of the process and the final categories, two researchers will conduct parts of the coding independently and discuss their results.

Sample size and power

Sample size calculation indicates that a total sample size of 142 patients is sufficient to detect medium group differences ($f=0.25$) with a power of 95% at a significance level of $p<0.05$. Considering two measurements, medium effects with a power of 85% can be detected with a sample size of 110.

For study arm 1 (study registries), there is an expected patient number of about 224 per year (calculated based on previous annual statistics). Based on an estimated 50% response rate and a drop-out rate of 30% during follow-up, about 118 patients can be included within 18 months of recruitment. However, since the distribution of users and non-users of rehabilitation measures in study arm 1 is unknown and the study has an observational design with a focus on exploratory analyses, we aim to include as many patients as possible during the recruitment period.

For study arm 2 (rehabilitation measure), there is an expected patient number of about 117 per year (calculated based on previous annual statistics). Based on an estimated 50% initial response rate and a drop-out rate of 30% in 24 months of recruitment, about 82 patients can be included.

ETHICS AND DISSEMINATION

The medical ethics committee of the Medical Chamber of Hamburg reviewed and approved the study protocol (date: 20 May 2016, number: PV5277). Written information are provided to children (≥ 11 years) and parents and they are asked to give their written informed consent prior to data collection. There are two different information and consent forms for children (11–13 years) and adolescents (14–17 years) with age-appropriate formulations. Parents additionally give their informed consent for their children (≥ 11 years). The project is a naturalistic, observational study. There is no additional study-specific

intervention besides the rehabilitation measure as a part of routine care within the framework of this study. The results of this project may help to optimise healthcare services that support the families after the end of cancer treatment with the re-entry into daily life.

The project duration is 42 months. The study was initiated in March 2016. Within the first 4 months, extensive preparatory work was carried out. The recruitment of participants in study arm 1 started in August 2016 and in study arm 2 in July 2016. Completion of data collection is planned to be in June 2019. Data entry, management and analysis as well as the publication of the findings in peer-reviewed journals and at conferences will take place continuously.

DISCUSSION

To the best of our knowledge, only few prospective, longitudinal studies have examined the situation of families with a child with cancer after the end of cancer treatment.^{19 26 53 54} So far, there is no study on processes of reintegration of all family members and no research on the role of rehabilitation measures in reintegration into daily life for affected families. The aim of this study is to investigate reintegration systematically and to explore factors associated with this process, especially focusing on rehabilitation measures. We aim to assess different trajectories of reintegration and to identify the role of rehabilitation measures for childhood cancer survivors and their families. The assessment of several outcomes from both the child's and the parent's view allows for a comprehensive, multiperspective insight in factors influencing reintegration. This might help to further the understanding of the situation of childhood cancer survivors and their families and to identify specific support needs with regard to reintegration. Therefore, the findings of this study may contribute to optimise healthcare services for families affected with childhood cancer and to develop aftercare programmes and interventions to facilitate the re-entry into 'normal' life of childhood cancer survivors and their families.
