ABSTRACT

Introduction Undisplaced femoral neck fractures (FNFs) are usually treated by internal fixation (IF) but two randomised controlled trials (RCTs) have demonstrated advantages of treatment with arthroplasty. The complication rate was lowered but there were no clinically improved patient-reported outcome measures (PROM), which could be due to underpowering or choice of selected PROM as the studies do appear to report a better functional outcome. We will conduct an RCT comparing IF with arthroplasties in patients aged over 65 years with an undisplaced FNF.

Methods and analysis All hospitals in Denmark treating patients with hip fracture can provide patients for this study; therefore, the study can be considered a national RCT. Patients over 65 years old with an undisplaced FNF will be screened for eligibility and patients will only be excluded if they are unable to understand the study information (due to dementia or language), if they have a posterior tilt >20°, a pathological fracture or they cannot walk. Participants will be electronically randomised (in alternating blocks of 4 or 6) into either IF or arthroplasty. Postoperative care will follow the department standards. Primary and secondary outcomes and measuring points have been established in collaboration with patients with hip fracture by focus group interviews. The primary outcome measure is the New Mobility Score assessed after 1 year. Secondary outcomes are the Oxford Hip Score, EuroQol 5 domain (EQ-5D-5L), degree of posterior tilt, pain Verbal Rating Scale, reoperation and mortality.

Ethics and dissemination The study is approved by the Danish Data Protection Agency (19/7429) and the scientific ethics committee (S-20180036). All participants will sign an informed consent before entering the trial. Because this is a national trial, all relevant healthcare professionals in Denmark will automatically receive the trial results that will be published in international peer-reviewed journals.

Trial registration number ClinicalTrials.gov Registry (NCT04075461).

INTRODUCTION

Arthroplasty for a displaced femoral neck fracture (FNF) in the elderly is recommended by most guidelines.^{1,2} For the undisplaced FNF, internal fixation is the only recommendation;

Strengths and limitations of this study

- National randomised controlled trial (RCT) on undisplaced femoral neck fracture comparing internal fixation with arthroplasty.
- It is a pragmatic RCT and each hospital can use their preferred implants.
- Primary outcome is an easily understood functional score, the New Mobility Score.
- Participants are only included if they are able to walk outside with no help from other individuals.
- The participants and assessors are blinded concerning implant.

however, it is questioned whether there is an alternative treatment.

Recently, two randomised controlled trials (RCTs) comparing internal fixation with hemiarthroplasty have been published.^{3,4} Both RCTs demonstrated a lower reoperation frequency in the hemiarthroplasty group (5%) compared with internal fixation (20%–21%). Lu *et al*³ found a slightly higher Harris Hip Score after 6 months and 1 year in favour of hemiarthroplasty but not thereafter. Dolatowski *et al*⁴ found a faster mobility (Timed-Up-And-Go) but no difference in the Harris Hip Score. These studies did not show a clinical difference in Harris Hip Scores, but this measure may not be the best primary outcome measure due to the ceiling effect and lack of validation for patients with hip fracture.⁵

Mobilisation after hip fracture is perhaps the most important factor for mortality after surgery⁶ and surgery should, therefore, aim for fast mobilisation. Arthroplasty may be a good choice, as it may yield faster recovery than internal fixation.⁷ A systematic review⁸ in 2008 of mobility instruments for older patients showed that no existing instrument had the properties required to measure and monitor the mobility of older acute medical

patients accurately. The New Mobility Score (NMS) developed by Parker may predict mortality,⁹ and Kristensen *et al* have since shown that it can also predict function better than Timed-Up-and-Go. NMS is easy to use and has a very high inter-tester reliability.^{10 11} Pedersen and Lauritsen¹² also demonstrated good correlation of NMS and gait function prediction with the same properties as Barthel-20 and Barthel-100 but with a lower ceiling frequency of 4 months postoperatively.

Even though the evidence is limited from the two RCTs,^{3 4} one could argue for implementing arthroplasty for undisplaced FNF since there are fewer reoperations and perhaps a faster mobilisation. However, a cohort study has demonstrated a higher mortality percentage when using hemiarthroplasty compared with internal fixation.¹³ This study does contain selection bias and confounding problems, as there are in general with cohort studies, which makes the resulting evidence limited for everyday clinical use. Therefore, we should conduct larger RCTs as hip fracture RCTs, in general, are small and underpowered.¹⁴ In addition, external validity is often a problem in traditional RCTs, because an inclusion rate as little as 7% was seen in the FAITH Study¹⁵ thereby questioning whether hip fracture trials exclude too many patients.¹⁶ A pragmatic RCT design includes a larger proportion of the eligible patients due to fewer exclusion criteria and could, therefore, be a better choice to test an intervention in everyday clinical setting.¹⁷

The aim of this trial is to compare functional outcomes of arthroplasty with internal fixation for patients over 65 years old with an undisplaced FNF. The study is designed as a national single-blinded pragmatic 1:1 RCT. The hypothesis states that arthroplasty is superior to internal fixation using the NMS as the primary outcome.

METHODS: PARTICIPANTS, INTERVENTIONS AND OUTCOMES

Study setting

The Danish National Health Service provides tax-supported free healthcare and general hospital care for all Danish citizens.¹⁸ All patients with hip fracture are treated at public hospitals in Denmark as no private hospitals in Denmark have any acute fracture treatment. Twenty public hospitals in Denmark treat patients with hip fracture and all participate in this study, making this trial a national RCT.

The trial started 1st of February 2020 but has been paused due to COVID-19. The sites will start recruitment at different time points from 1st of July to 1st of October.

Trial design

The study is designed as a national pragmatic RCT, including all patients with an undisplaced FNF and an NMS of 5 and above. The current standard treatment in Denmark is internal fixation, and patients are randomised to either arthroplasty or internal fixation. The steering group has assessed the pragmatic attitude of the design and the study reaches five points in seven of the nine

Figure 1 Assessment of pragmatic design using the PRagmatic EXplanatory Continuum Indicator Summary-2 wheel.

domains (figure 1).¹⁷ Reporting will be performed according to the extension of the Consolidated Standards of Reporting Trials statements for a pragmatic RCT,¹⁹ and this protocol is reported according to the Standard Protocol Items: Recommendations for Interventional Trials statement.²⁰

Eligibility criteria

All patients with an undisplaced FNF classified as either Garden type I or II²¹ are evaluated. The patients are included if:

- ▶ Age ≥ 65 years.
- ▶ Undisplaced FNF.
- ▶ Posterior tilt²² $< 20^\circ$.
- ▶ NMS=5 and above, indicating an ability to walk prior to the fracture.
- ▶ Cognitive state intact to achieve informed consent.

Patients are excluded if:

- ▶ The fracture is pathological.
- ▶ The patient does not speak or understand Danish language.

To ensure correct fracture classification, an adjudication committee will evaluate all included X-ray images.

Interventions

Participants are randomised to either arthroplasty or internal fixation. Because the treatment options at each hospital may be very different, arthroplasty can include total hip arthroplasty (cemented, uncemented, hybrid, dual-mobility cup) or hemiarthroplasty (cemented, uncemented) using the institution's regular surgical approach (18 hospitals only use the posterior approach). Internal fixation can include either two or three screws/pins or a sliding hip screw. After discharge, all patients will be referred to standard rehabilitation in the municipalities and will be seen in their own home or at the orthopaedic

department for outcome assessment after 3, 6 and 12 months. X-ray will be performed postoperatively within discharge and after 12 months.

Outcomes

Primary and secondary outcomes and measuring points have been established in collaboration with a focus group interview with patients with hip fracture. The primary outcome measure is NMS assessed after 12 months. NMS will also be assessed at baseline, 3 and 6 months.

Secondary outcome measures evaluated at the same time points are the Oxford Hip Score, EuroQol 5 domain, pain Verbal Rating Scale,²³ reoperation (any surgery related to the implants including closed reduction) and mortality. Explorative outcome measures are the de Morton Mobility Index,^{7 24} Barthel-20,²⁵ Cumulated Ambulation Score,²⁶ X-ray measurements and activity tracking.

Information will be retrieved from patient interview and healthcare records on the following:

- Demographics: age, sex, residency, prefracture mobility.
- Comorbidity: American Society of Anaesthesiologists Classification, diseases, medication, smoking, alcohol.
- Admission: time of admission, duration of hospital stay, concurrent infection, fracture time.
- Surgery: start and end of surgery, type of implant, surgical experience, blood loss.
- X-ray: quality of implant positioning.^{27–29}
- Biochemistry: haemoglobin, leucocytes, C reactive protein, estimated glomerular filtration rate, international normalised ratio, blood transfusions.

- Complications: postoperative medical complications (all possible such as heart, lung, abdominal, brain, electrolytes, fall and infection), readmissions.

A timeframe for the collection of data is provided in [table 1](#). Healthcare record information is collected for research purposes only to compare patient groups and treatment.

Sample size calculation

A minimal clinically important difference in NMS of 1 point was taken from Kristensen's thesis³⁰ and a 1-year average of 6.4 points with an SD of 2.2 from Steihaug *et al.*³¹ The sample size was calculated using a 1-point difference, an SD of 2.2, allowing a 5% probability of type 1 error and applying 95% statistical power. Consequently, 127 patients are required in each group and to allow for loss during follow-up due to mortality and other causes (30%). Therefore, a total of 330 patients are required for the study.

Recruitment

All patients are recruited in the emergency department when diagnosed with an undisplaced FNF. The admitting doctor or a senior consultant will inform the patient about the trial while the patient is in the emergency department. The information will be given verbally as well as by written participant information in an undisturbed room in the emergency department. If no next of kin are present, they will be invited to attend by phone if requested by the participant. Otherwise, an impartial assessor can be assigned. Because surgery is required to take place as quickly as possible due to a higher risk of

mortality when delaying surgery, a reflection time of only 2 hours has been approved. Retrieval of informed consent will take place at either the emergency department or the ward.

Patient and public involvement

We conducted a focus group interview with patients with hip fracture with internal fixation or arthroplasty at Hospital Lillebaelt, which involved six patients (and their relatives) aged 70–94 years who had received surgery 6–12 months prior to the interview. They were interviewed using a structured interview guide. The interview consisted of open questions regarding their hip fracture experience, their subsequent consequences/challenges and what was important for them to regain. Further questions relating specifically to the study were also included. The questionnaires were easily understood, and all found them relevant. All questions were answered, and the most important outcome reported was for all functional outcomes, especially the ability to walk properly. Pain was also an important consideration, especially for the internal fixation group. All participants felt that the most important time for measuring outcomes would be after 1 year, but measuring during the first year was also important.

The study protocol was presented to the Patient and Relatives Council at Hospital Lillebaelt afterwards, with no additional remarks.

METHODS: ASSIGNMENT OF INTERVENTIONS

Allocation

Treatment is divided into two strands and patients eligible for inclusion can be enrolled if they provide informed consent. Patients are entered into an electronic database (REDCap) and thereafter randomised using random blocks of $n=4$ or $n=6$ stratified by hospital. When the patient is called to the theatre, the surgeon will determine which implant to use by consulting REDCap; accordingly, REDCap will be used to create two groups representing each implant type.

Blinding

The surgeon and theatre staff cannot be blinded, but a standard phrase for the surgery will be used to blind the patient. According to standards of care and journal publication requirements, the coordinating staff can reveal the true surgery in case of severe pain or complications; otherwise, patients will not know until the end of the trial. The assessors will assess patients in their own home and will be blinded according to the type of surgery.

Methods

Data collection, management and analysis.

Data collection methods

Data will be collected by project staff. Baseline data will be collected during admission, and all data concerning patient-reported outcomes and physical assessment are

collected by a physiotherapist in the patient's own home or in the outpatient clinic depending on the participant's wish.

Data management

Data will be entered directly into the project's REDCap database when assessing or interviewing the participants.

Statistical methods

All variables are described according to their distribution. Groups will be compared by linear mixed models for numerical data and logistic mixed models for dichotomous data including a random effect for hospital. Both unadjusted analyses as well as analyses adjusting for demographic variables, comorbidity, mobility, type of implant, reoperation and mortality will be carried out. Distributional assumptions on residuals and random effects will be investigated by quantile–quantile plots, and in case of deviations from distributional assumptions bootstrapping with 1000 replicates will be used to estimate CIs and p values. All group comparisons will be carried out both as intention-to-treat analysis and per-protocol analysis. Mortality will be analysed by Cox-regression with baseline hazards stratified by hospital. As sensitivity analyses competing risk regression models will be applied.

Methods: monitoring

Data monitoring

After data retrieval from the first 70 patients, an interim analysis will be performed regarding mortality and function. If there is a difference of 10% in 30 days mortality, a consensus decision by steering group whether the trial should be stopped will be conducted. Likewise, if the NMS score shows 2 points or more difference after 3 months, all authors are asked whether the trial should be stopped. This is because the required sample size would then be 66 patients.

Potential harms

Any unforeseen complications that occur during the trial will be registered in the project's REDCap database.

Auditing

An adjudication committee will audit all X-ray images.

ETHICS AND DISSEMINATION

Research ethics approval

The study is approved by the Danish Data Protection Agency (19/7429) and the Scientific Ethics Committee with the project ID number S-20180036. It was first approved on the 15th October 2018 and a revision was approved 8th October 2019.

Consent or assent

The orthopaedic surgeon on call is responsible for including patients. The patients have to give a written consent (online supplemental appendix 1) before entering the trial.

Confidentiality

Project data are securely stored in the project's REDCap database, and when the trial is completed, data are stored in the Danish Data Archive.

Ancillary and post-trial care

Any patients who experience any harm due to this trial will have the same care as all other patients in Denmark through the independent Danish Patient Compensation Association.

Dissemination policy

This is a national trial and all 20 hospitals providing hip fracture care are included. All relevant healthcare professionals involved in hip fracture treatment in Denmark will, therefore, automatically be informed of the trial results. The results will also be published in international peer-reviewed journals.

Perspective

By conducting a national pragmatic RCT, external validity will potentially be high. A general problem with trials is the lack of clinical impact afterwards as one paper has shown that it takes an average of 17 years for new findings to reach clinical practice. As this is a nationwide study, the impact of the results is expected to be immediate and high.
