ABSTRACT

Introduction Laparoscopy has partially replaced open surgery due to the lower infection rate for the patient and hence better and shorter recovery. However, the surgeon's physical load is higher due to longer duration static and awkward body postures, increasing the risk for developing work-related musculoskeletal disorders. Interventions of an organisational nature are work breaks, being either passive or active. The primary objectives of this study are to determine whether passive and active work breaks lead to less discomfort than no work breaks and whether active work breaks lead to less discomfort than passive work breaks.

Methods and analysis A controlled, randomised cross-over trial will be performed in the laboratory, of which its protocol is described here according to the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) 2013 Statement. Recruitment of 21 laparoscopic surgeons started in April 2019 and the study is ongoing. The participating surgeons will perform three 1.5 hour experimental conditions, one without work breaks, one with 2.5 min passive work breaks including rest, and one with 2.5 min active work breaks including mobility and stretching exercises. The work breaks will be taken after 30 and 60 min of work. During the experiments, outcomes will be recorded. The primary outcome is rating of perceived discomfort measured on an 11-point numeric rating scale. The secondary outcomes are performance, muscle activity of selected muscles, upper body angles, heart rate, workload and subjective evaluation of both interventions. The collected data will be tested using a one-way or two-factorial repeated-measures analysis of variance.

Ethics and dissemination Ethical approval of the study protocol was received by the local medical ethical committee of the University of Tübingen in February 2019 (no 618/2018B02). The results of this study will be presented at national and international conferences, submitted for publications in peer-reviewed journals and serve as the starting point for a feasibility study.

Trial registration number NCT03715816.

INTRODUCTION

Background

The first known laparoscopic intervention in humans was performed in 1947 in France.¹

Strengths and limitations of this study

- The described study will be among the earliest comparing active and passive intraoperative work breaks against no breaks in a simulated laparoscopic setting, applying a controlled, randomised cross-over design.
- The study cannot be blinded, that is, the researchers know to which experimental condition (control or intervention) the participant is randomly allocated and the participants know after start of the measurement to which experimental condition (control or intervention) they are exposed.
- The primary outcome is perceived rating of discomfort, which will provide valuable information whether the participating surgeons experience the implemented work breaks as promising or not.
- Activity of muscles involved in laparoscopic work, upper body posture and heart rate are secondary outcomes for this study that are objectively measured and may support the results of the primary outcome.
- The trial is not designed to detect differences in secondary outcomes or subgroups, which means that these will be considered following an exploratory approach and be hypothesis generating.

This technique, also known as minimally invasive surgery (MIS), has partially replaced open surgery because it reduces patient's postsurgical pain due to the smaller incisions and is hence characterised by lower infection rates and shorter recovery times.^{2–4} Besides the sources of psychological stress that surgeons have to deal with, such as work pressure and dealing with the patient's well-being,⁵ MIS additionally creates increased exposure to sources of physical stress, such as static loading and awkward body postures.^{6,7} These external, physical stressors increase the physical strain on the surgeon and may, consequently,

increase the risk of developing work-related musculoskeletal disorders (WRMSD).^{8,9} According to a recent review of the literature, prevalence rates of WRMSD among endoscopists, urologists, gynaecologists, otolaryngologists and ophthalmologists performing MIS range between 43% and 88%.¹⁰ The most affected body sites are the neck, back and shoulders.^{11,12}

Two types of interventions addressing the working conditions could potentially be applied to counteract the prevalence of WRMSD in the surgical environment: interventions related to workplace factors and interventions related to work-organisational factors.¹³ A first example of improving workplace factors is to use ergonomically designed surgical equipment, since many different instrument handles are available.^{14,15} Among others, two studies have evaluated the use of rotatable handle pieces to decrease the time spent in awkward hand, arm and wrist postures.^{16,17} Both studies concluded that wrist postures were less extreme in case the instruments with rotatable handle piece were used. An ergonomic articulating laparoscopic grasping tool has been evaluated and was preferred over a conventional laparoscopic grasping tool because the participating surgeons experienced less hand pain, stiffness and numbness with the articulating tool.¹⁸ Another example of improving workplace factors is the implementation of ergonomic supports that could reduce the amount of physical stress in the body.¹⁹ A laboratory study that evaluated an arm support system showed that it did not change the shoulder, arm and hand posture of the surgeon.²⁰ Another study evaluated a body support and found promising results by concluding from subjective reports that the body support, which was a type of stand support, could be an effective way to reduce perceived discomfort.²¹ A more recent study developed a surgical knee rest to decrease stress placed on the lower extremities during surgery in a standing position and found that the muscle activity of the gastrocnemius decreased.²²

The most well-known example of an intervention that relates to work-organisational factors is the implementation of load alternating rest periods or breaks. A strong advantage of implementing work breaks is that not only the surgeon may benefit, but also other medical personnel involved in the surgical procedure. A recent systematic review, however, found solely randomised controlled trials performed among workers using visual display units without any evidence for positive associations of different types, durations and frequencies of work breaks on musculoskeletal outcomes.²³ Taking breaks during surgeries does not appear to be a common habit, according to a recent survey study, within which only 4.8% of the laparoscopic surgeons indicated experiencing scheduled intra-operative breaks.^{24,25} However, several studies performed in the surgical field that were not randomised controlled trials actually have shown promising results, of which the most important are no prolonged surgery duration,^{26,27} reduced discomfort mainly at the shoulders, neck, hands and back,^{27–29} and reduced error rate.^{26,28} Engelmann *et al*²⁶ investigated 5 min passive work breaks, whereas

Dorion and Darveau,²⁸ Hallbeck, *et al*²⁹ and Park *et al*²⁷ investigated active work breaks containing stretching exercises for a 20 s²⁸ or 1.5 min^{27,29} duration every 20–40 min working period. Two more recent studies focused on the development of either an optimised active work-break structure³⁰ or a web-based application that video guide the surgeon to perform some stretch work breaks.³¹

Objectives

The primary aims of this study are to investigate during 1.5 hour simulated laparoscopic surgery activities whether:

- ▶ ... passive work breaks alleviate discomfort when compared with no work breaks;
- ▶ ... active work breaks alleviate discomfort when compared with no work breaks;
- ▶ ... active work breaks alleviate discomfort more than passive work breaks.

The secondary aims of this study are to investigate during 1.5 hour simulated laparoscopic surgery activities whether:

- ▶ ... passive work breaks when compared with no work breaks...;
- ▶ ... active work breaks when compared with no work breaks...;
- ▶ ...active work breaks when compared with passive work breaks...;

...lead to changes in performance, static muscular activity, median muscular activity, peak muscular activity, muscular fatigue, upper body postures, heart rate (HR), heart rate variability (HRV) and perceived workload. Additionally, feedback about some implementation aspects of both work break interventions will be evaluated, that is, content, frequency, duration, performance and concentration.

METHODS AND ANALYSIS

The protocol of the here described controlled, randomised cross-over trial is based on the guided checklist provided by the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) 2013 Statement.^{32,33} The study protocol has been registered at clinicaltrials.gov (NCT03715816).

Study design

Two different work break interventions, that is, a passive and active work break intervention (for more information, see Work break intervention), will be compared with the control condition, within which no work break intervention will be implemented. All three scenarios will be investigated during simulated laparoscopy in a controlled, randomised cross-over trial. We have chosen that each subject acts as his own control to keep the necessary sample size to a minimum. The study will take place in the laboratory and will not be blinded, that is, the researcher will not be blinded to the intervention to which the participant is randomly allocated and the participant will not be blinded to the intervention.

Consent of study participants

A written informed consent and written data privacy consent are necessary prior to study enrolment, which are obtained by the researcher who is leading the familiarisation trial. The eligible participant has the ability to have an informed discussion with the researcher about the trial and gather additional information if desired. A template informed consent form and data privacy consent form can be found translated from German in online supplemental material 1 and 2.

Recruitment and eligibility criteria

Due to a close collaboration with the Department of Gynaecology (DOG) of the University of Tübingen (UKT, Germany), study participants, that is, laparoscopic surgeons, are recruited by means of direct advertisement and internal email announcements. During the first visit at the laboratory, the participants have the study explained to them by the researcher, after which they will be examined whether they fulfil the inclusion and exclusion criteria (see below) for study participation. When they are willing to voluntarily participate in the study, they have to sign informed and data protection consents (see online supplemental material 1 and 2).

Inclusion criteria

- ▶ Aged 18 years or older at the time of participation.
- ▶ Sufficient understanding of the German language.
- ▶ Experience with (simulated) laparoscopic activities.
- ▶ Ability to perform the peg transfer task within 3 min, which is a standardised task and part of the Fundamentals of Laparoscopic Surgery (FLS) as introduced by the Society of American Gastrointestinal Endoscopic Surgeons (SAGES).³⁴ This task tests eye-hand coordination, ambidexterity and depth perception, by grasping six objects with the left hand, transferring each object to the right hand and placing each object on the right side of the pegboard (for more information, see Experimental procedure).

Exclusion criteria

- ▶ Less than 18 years old at the time of participation.
- ▶ Not being able to perform the standardised peg transfer task³⁴ within 3 min.
- ▶ Having one of the following (anamnesic) disorders, disabilities or conditions: sensory disturbances; vascular diseases; cardiovascular diseases; muscular disorders; heart disease (e.g., pacemaker); severe muscular contractions; acute pain; diabetes mellitus; Parkinson's disease; symptomatic sensory or motor polyneuropathy; alcohol abuse; severe muscle contractions; under the influence of intoxicants, analgesics or muscle relaxants; symptomatic neurological-psychiatric diseases.
- ▶ Not being able to complete the examination programme due to language or cognitive obstacles.
- ▶ Blood pressure of $\geq 139/\leq 100$ mm Hg, which may hinder the participant to perform maximal voluntary

contractions (MVC) that are necessary for normalisation of the measurement of muscle activity.

Work-break intervention

Duration, frequency and timing of the intervention

Previous research that was performed in another field of work showed that 30 s work breaks after 30 min of work may not be sufficiently long to lead to any effects on perceived discomfort.³⁵ More recent studies showed that 1.5, 2 and 5 min work breaks after 20–40 min of surgical work may be effective in reducing perceived discomfort among surgeons.^{26 27 29} Based on the positive effects of these studies, the duration of the work breaks that will be implemented in the current study will be 2.5 min and provided after 30 min of surgical work, which is a good compromise between previously shown effective pause durations without longer surgeries.

Although previous studies investigated the effect of work breaks within 120,^{27 28} 150²⁹ or 180 min surgery durations,²⁶ the current study will implement two 2.5 min work breaks within a 90 min simulated laparoscopic surgery. The reasons for this 90 min laparoscopy duration are the controlled study design, the simulation in the laboratory and the fact that laparoscopic surgeries last on average about 75 min.³⁶

Content of the intervention

The 2.5 min interventions can be offered with different contents and can consequently be considered as passive or active breaks. Both types of work breaks have been investigated in the surgical field of work. In the study of Engelmann *et al*,²⁶ unstructured passive work breaks have been applied, that is, when workers just rest, in line with the definition of Luger *et al*.²³ In the current study, the surgeon will undergo a 2.5 min passive work break, that is, the surgeon just rests, while standing and remaining in his position next to the laparoscopic setting, allowing him to lay down the laparoscopic instruments.

The active work breaks are defined according to literature to contain stretching, mobility or relaxing exercises, walks or cognitive tasks.²³ The studies performed in the surgical field of work that investigated the implementation of active work breaks mainly contained stretching exercises.^{27–29} For the current study, we wanted the exercises to be designed for target body regions within which surgeons regularly report perceived feelings of discomfort, fatigue or pain or even WRMSD and the exercises to focus on (1) posture correction, (2) normalisation of tissue tension and soft-tissue mobility or (3) relaxation.³⁰ We aimed to develop an active work break intervention, especially covering the first two aspects of Coleman Wood *et al*,³⁰ that is, posture correction and normalisation of tissue tension and mobility. Based on preliminary results of a survey study among laparoscopic surgeons, the main body regions for which discomfort or complaints were reported were the neck (67%), shoulders (65%) and lower back (64%).^{24 25} In collaboration with a physiotherapist of the UKT, a set of seven different exercises

was developed, for which standardised instructions were provided of which an audio recording is made (spoken by author BS) that is played back when the participating surgeon has the condition with active work breaks (see online supplemental material 3 for a detailed description of the exercises):

1. Whole-body mobilisation exercise.
2. Hip mobilisation exercise.
3. Lower back stretching exercise.
4. Upper back and shoulder stretching exercise.
5. Shoulder mobilisation exercise.
6. Neck stretching exercise.
7. Neck mobilisation exercise.
8. Whole body mobilisation exercise.

The number of repetitions and the range of motion of each of the exercises were not controlled for since the applied exercises were meant to activate all relevant body locations at very low exercise intensity unlikely to induce adaptations in, for example, muscle strength.³⁷ The researcher controlled for the participant performing the exercises during the complete time window given on the standardised audio recording.

Study outcomes

The demographic and background outcomes will be collected at baseline during the familiarisation trial, whereas the primary and secondary outcomes will be assessed during the laboratory measurements. All outcomes are listed in table 1.

Sample size

Due to a lack of data from literature, we were not able to estimate the correlation between the three experimental conditions, which is necessary to calculate the sample size for a within-subject design.^{38 39} Therefore, we used a conservative approach to determine the sample size based on the formula for the sample size for a between-subject design (Equation 1).⁴⁰ The required sample size was calculated for the primary outcome, rating of perceived discomfort (RPD). We used Equation 1,⁴⁰ with a level of significance and study power of 5% and 80%, respectively. The effect sizes and pooled SD were derived from a study that investigated intraoperative 20s active work breaks every 20 min during surgeries lasting at least 120 min and compared it against no work breaks.²⁸ The authors reported findings of the perceived level of discomfort using a 100 mm visual analogue scale (VAS) from which a general effect size and general pooled SD of 16.8571 and 19.3372 could be calculated, respectively. When directly translated to an 11-point (0 to 10) numeric rating scale (NRS), the effect size and pooled SD would be 1.6857 and 1.9337, respectively. These numbers result in a required sample size of 21 participants, excluding potential drop-outs

$$n = \frac{2 \cdot (Z_{\alpha} + Z_{1-\beta})^2 \cdot \sigma^2}{\delta^2} \quad (1)$$

Table 1 Collection of study outcomes, divided into primary, secondary and demographic outcomes

Primary outcome	Secondary outcomes	Demographic outcomes
Rating of perceived discomfort	Performance hot wire task *	Primary job description
	Performance peg transfer task *	Total laparoscopic experience(years)
	Static electrical activity of arm, shoulder and back muscles†	Total of laparoscopies carries out to date(#)
	Median electrical activity of arm, shoulder and back muscles†	Current average of laparoscopies/week(#)
	Peak electrical activity of arm, shoulder and back muscles†	Age
	Lumbar lordosis	Gender
	Thoracic kyphosis	Body height
	Cervical lordosis	Body weight
	Heart rate	Smoking status
	Workload	Sport hours/week(#)
	Subjective evaluation of the intervention	Musculoskeletal status

*The hot wire task and peg transfer task will be described in more detail under Methods and analysis >Experimental procedure

†The static, median and peak electrical activities of the various muscles will be determined by recording of surface electromyography, which is described in more detail under Methods and analysis >Data collection >Secondary outcomes.

with n the sample size; Z_{α} the constant z -value based on the accepted two-sided level of significance or α error (ie, 5% or 0.05), resulting in a value of 1.96; $Z_{1-\beta}$ the constant z -value based on the chance to miss a real difference (ie, the inverse of the study power of 80% or 0.80), resulting in a value of 0.8416; σ the pooled SD based on previously reported data (here: 1.9337); the effect size or difference in effect of two interventions based on previously reported data (here active vs no work breaks: 1.6857).

Study duration and participant timeline

The study is planned to last for a total of one-and-a-half to two calendar years. Study preparation, including ethics approval and pilot testing, lasted about 3 months. Subject recruitment started in March 2019 and, together with data collection, is estimated to last until the summer of 2020.

Study participants are informed to take into account a study-related time commitment of four appointments spread over four different days, including one familiarisation trial (about 1 hour) and three experimental trials (about 2.5 hours; see figure 1). During the familiarisation trial, the participants will go through the active work break script together with the researcher to get familiar with the

Figure 1 Flow chart displaying the process of the cross-over study. Participants will be randomly allocated by the principal investigator (TL) to one of the six possible orders of the three conditions.

mobility and stretching exercises. The researcher informs the participating surgeon that the goal of the exercises is to perform them during the given time window in a way that it feels comfortable for them, meaning the range of motion and number of repetitions of each exercise are not controlled for. Each participant will receive a small financial compensation after full participation.

Randomisation

The order of the three conditions will be assigned to the participating surgeon by drawing a lot from a box by the principal investigator (TL). Six different orders of conditions are possible (ABC | ACB | BAC | BCA | CAB | CBA; cf. figure 1) of which the fourfold can be found written on paper in the box.

Experimental procedure

The 90-minute experiment will consist of tasks with which laparoscopic psychomotor skills will be simulated in a Pelvic Trainer (Szabo, ID Trust Medical, Belgium). The Pelvic Trainer is a validated endoscopic device used by hospitals and universities to train medical students and other staff the laparoscopic tasks without the risk of harming patients. The optics in the Pelvic Trainer, that is, camera with light source (Karl Storz 26003AA HOPKINS II Optik 0°, Karl Storz SE & Co. KG, Tuttlingen, Germany), will be in a fixed position and connected to a screen in front of the participant to display the task. The light intensity and operation room temperature were randomly measured prior to onset of the study in the operation theatre of the DOG at the UKT, and ranged 5–17Lux (Light Meter, LX-107, Lutron Electronic Enterprise Co., Taipei, Taiwan) and 22.8°C to 26.2°C (Thermometer, OPUS10 THI, SwiCAL swiss calibration GmbH, Bern, Switzerland), respectively. The laboratory temperature

was regulated and ranged between 24°C and 26°C; the light intensity in the room ranged between 5 and 9Lux.

The tasks included in the 90min simulations will be described below in more detail. Directly before and after the 90min simulation, a hot-wire task is executed. This task is performed without time restrictions and therefore not included as part of the 90min simulation. The simulation itself will consist of three 30min blocks, each comprising five different simulated laparoscopic tasks that will be performed in a set order: peg-transfer, pick-and-place, pick-and-tighten, peg-transfer, pick-and-thread, pull-and-stick, peg-transfer. These tasks are chosen because they mimic handlings the laparoscopic surgeons perform during their daily operational tasks, including hand-eye coordination, ambidexterity, needle transferring and accuracy.⁴¹ A picture of all six tasks is presented in figure 2 and a schematic time course of the conditions including two work breaks after 30 and 60min of simulated laparoscopy is displayed in figure 3. The active work break will be guided by a standardised audio recording of the exercises (cf. Content of the intervention). A foot pedal is integrated in the pick-and-place and pick-and-thread tasks to simulate coagulation, which is an action that occurs in many laparoscopic procedures in the field of gynaecology.

The hot-wire task is performed by the dominant hand, for which the participant has to move a metal ring that is held by a 34cm long laparoscopic Maryland bipolar forceps (model no. 20195-225, ERBE Elektromedizin GmbH, Tübingen, Germany) from the right side to the left side of a hot-wire and back. The primary goal is not to touch the hot-wire because that will produce a beeping sound, and the secondary goal is to simultaneously move the ring back and forth along the wire as fast as

Figure 2 The six tasks performed within the Pelvic Trainer: hot-wire (A), peg-transfer (B), pick-and-place (C), pick-and-tighten (D), pick-and-thread (E), pull-and-stick (F).

possible. The hot-wire is curved in 2D and is 21.5 cm long. Performance time of the hot-wire task is tracked using a regular stopwatch (model no WT-035, BASETech, Conrad Electronic SE, Hirschau, Germany) and both trials are recorded using an audio-recording device (Linear PCM Recorder LS-P1, Olympus GmbH, Hamburg, Germany).

The standardised peg-transfer task is performed bimanually with a 33 cm long forceps with 1:2 teeth (RS225-595, RUDOLF Medical GmbH & Co. KG, Fridingen, Germany) in the right hand and a 33 cm long forceps without teeth (33321 KW, KARL STORZ SE & Co. KG) in the left hand. The participant has to move green and orange triangles from pins oriented in a circle on the left to pins oriented in a rectangular on the right of the peg-transfer-board (Simulab, Seattle, Washington, USA) and back. The task is performed by taking the triangles from the pins on the left with the instrument in the left hand, transferring it to the instrument in the right hand and placing it on the

pins on the right. The peg-transfer task is performed for exactly 60 s and is repeated nine times during each experimental condition. The peg-transfer task is part of the FLS as introduced by the SAGES³⁴ and has shown high reliability (intraclass correlation coefficient (ICC) of 0.89 to 0.99) and good validity (predictive values above 0.80).⁴²

The pick-and-place task is performed bimanually with a 33 cm long forceps with 1:2 teeth (RS225-595, RUDOLF Medical GmbH & Co. KG) in the right hand and a 33 cm long forceps without teeth (33321 KW, KARL STORZ SE & Co. KG) in the left hand and will last up to 6.75 min. The participant has to take a red or blue bead (diameter 5 mm) from a wooden box (length 78.8 mm, height 61.8 mm, depth 57.8 mm) that can be opened by a foot pedal and place it on the square pegboard (8×8 cm) with 14×14 pins according to the pattern hanging in the very back of the Pelvic Trainer. The beads have to be picked and placed in a predefined order, namely from the upper

Figure 3 The 90+5 min time course of tasks including work breaks; for the condition without breaks, the blue blocks disappear. Each block and letter relates to a task, including the hot-wire (A), peg-transfer (B), pick-and-place (C), pick-and-tighten (D), pick-and-thread (E) and pull-and-stick task (F). The arrows indicate the time points of recordings of rating of perceived discomfort (T_{1-9}) and recordings of muscle activity, upper body posture and heart rate (B_{1-9}) during the peg-transfer task (B).

left to the lower right corner. The box remains open for 5 s after operating the foot pedal.

The pick-and-tighten task is performed bimanually with a 33 cm long forceps with 1:2 teeth (RS225-595, RUDOLF Medical GmbH & Co. KG) in the right hand and a 33 cm long forceps without teeth (33321 KW, KARL STORZ SE & Co. KG) in the left hand and will last up to 6.75 min. The participant has to take a red rubber band (diameter 160 mm, thickness 1 mm, width 5 mm) with one of both laparoscopic instruments and stretch it over two wooden dowels (diameter 10 mm, height 32 mm). The task set-up contains eight dowels, positioned in a radius of 102.1 mm with a space of 65 mm in between consecutive dowels. When stretching a rubber band over two dowels, two have to be skipped, which makes the distance over which the rubber band has to be tightened 165 mm. In total, eight rubber bands have to be picked from the lower left corner of the task set-up consecutively and tightened over pairs of dowels by starting at the top dowel (ie, 0 o'clock) and continuing clockwise. When this is finished, the rubber bands will be taken down to the lower right corner of the task set-up, after which the picking and tightening will start again from the top dowel (ie, 0 o'clock) but now counterclockwise. When this is finished again, the rubber bands will be taken down to the lower left corner of the task set-up and the task is continued from the start.

The pick-and-thread task is performed bimanually with a 33 cm long KOH macro needle holder (26173 KAR, KARL STORZ SE & Co. KG) in the right hand and a 33 cm long forceps without teeth (33321 KW, KARL STORZ SE & Co. KG) in the left hand and will last up to 6.75 min. The participant will pick a bead with the instrument in the left hand from the wooden box, which is opened using the foot pedal, and thread it onto a half-circle, round, blunt needle that is connected to a 45 cm thread (Type RB6144, Mersilene, Ethicon US, LLC) that is held by the instrument in the right hand. Each bead that is placed over the blunt needle should be pulled onto the thread before the next bead is taken. There are no prescriptions for a colour code of the threaded beads.

The pull-and-stick task is performed bimanually with a 33 cm long forceps with 1:2 teeth (RS225-595, RUDOLF Medical GmbH & Co. KG) in the right hand and a 33 cm long forceps without teeth (33321 KW, KARL STORZ SE & Co. KG) in the left hand and will last up to 6.75 min. The participant has to take off self-adhesive, round, paper marking points (diameter 8 mm) from a stapling paper (9×5 lanes, 107.5×55.0 mm) on the upper part of the task set-up and stick them on an empty paper on the lower part of the task set-up (107.5×55.0 mm). There is no prescription in which order the marking points should be pulled and stuck.

Data collection

Baseline demographics, including current primary job description, total laparoscopic experience in years, total number of laparoscopies carried out to date, current average number of laparoscopies performed per week,

age, gender, body height, body weight, smoking status, and sport hours per week will be captured during the familiarisation trial (see demographics in [table 1](#)). Additionally, participants will fill out the German version⁴³ of the standardised Nordic Musculoskeletal Questionnaire (NMQ). The standardised NMQ is developed in English and has shown a test-retest validity of at least 77% and an inter-rater percentage disagreement reflecting reliability of at least 0.87.⁴⁴ Although no real validation study has been set-up for the NMQ, this questionnaire has been accepted and is still frequently used in various occupational settings to identify the prevalence of work-related musculoskeletal symptoms.^{45–48}

While the familiarisation trial will be supervised by one study leader, two study leaders are needed for the three experimental conditions. One of them will be responsible for the participant and the rapid change of tasks in the Pelvic Trainer; the other will be responsible for monitoring the quality and executing and recording both the continuous and discontinuous measurements.

Primary outcome

Rating of perceived discomfort (RPD)

Data of RPD will be collected on eight different time points: directly before and after the complete simulation and shortly after start and shortly before end of each 30 min block by one single item (see [figure 3](#)). An 11-point NRS will be used for the RPD running from 0 (no discomfort at all) to 10 (maximum imaginable discomfort).⁴⁹ For reporting musculoskeletal pain, the English version of the NRS has shown excellent reliability (ICC of 0.95) and good to excellent validity with Pearson correlation coefficients with the VAS and verbal rating scale of 0.94 and 0.93, respectively.⁵⁰ Although the 11-point NRS has not been validated for reporting musculoskeletal discomfort, we assume it is an appropriate method to assess our primary outcome RPD.

Participants will be asked whether they experience discomfort; if the answer is yes, they will be asked how much discomfort they experience and in which body region(s) according to the body map of Corlett⁵¹ (cf. [figure 4](#)). The concept of RPD, the response scale (ie, VAS), and how discomfort is asked for nine times during each of the experimental conditions ([figure 4](#)) is explained in the familiarisation trial, which takes place on a separate day prior to the experiment.

Secondary outcomes

Performance

Performance of the hot-wire task will be tracked as the relative part of the total time (%) the hot wire was not touched during the first repetition prior to the simulation (A_1) and the second repetition directly after the simulation (A_2). For the peg-transfer, performance will equal the total amount of pegs transferred within the provided 60 s timeframe. The first (B_1) and last (B_9) repetitions will be used for statistical analysis.

Figure 4 Left: guiding questions to ask the subject's perceived feeling of discomfort. Right: body map adapted from Corlett⁵¹ to define the body regions.

Muscular activity and muscular fatigue

Muscular activity will be recorded continuously using surface electromyography (EMG), for which two electrodes will be placed over each muscle belly, separated by an inter-electrode distance of 25 mm. EMG of the following muscles will be recorded: Mm. erector spinae longissimus lumbalis (bilateral), trapezius descendens (bilateral), deltoid acromialis (right side), extensor digitorum (right side) and flexor carpi radialis (right side). From the EMG signals, the root-mean-square (RMS) and median power frequency (MPF) can be calculated. The RMS will be expressed as a per cent of the RMS during the MVC, that is, maximal voluntary electrical activity (%MVE). MVC is performed for each muscle in twofold prior to each of the three experimental conditions. The MPF will be expressed in Hertz (Hz). In all cases, we will evaluate the static, median and peak level of RMS for each muscle, which can be determined by the 10th, 50th and 90th percentiles of the RMS signal over a specific recording period. For each of the muscles, the average of the 10th, 50th and 90th percentiles of RMS for the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task will be calculated (cf. figure 3). If the quality of the data is sufficient, we may be able to evaluate the development of localised muscular fatigue, for which the change (ie, slope expressed as change per minute) across the median RMS (RMS_{SLOPE} (%MVE/min)) and MPF (MPF_{SLOPE} (Hz/min)) will be calculated over the third (B_3), sixth (B_6) and ninth (B_9) peg-transfer task (cf. figure 3) and be plotted against each other in joint analyses of the EMG spectrum and amplitude (JASA).⁵²

Upper body posture

Motion of the upper body will be recorded using position sensors placed on the forehead, thoracic vertebrae T1 and T10, and lumbar vertebrae L1 and L5. The

difference in the flexion angles with respect to the absolute perpendicular (gravitational axis) of three pairs of sensors will be used to calculate the cervical lordosis (forehead–T1), thoracic kyphosis (T1–T10) and lumbar lordosis (L1–L5). The difference in the lateral flexion angles with respect to the absolute perpendicular of one pair of sensors will be used to calculate the neck lateral flexion angle (forehead–T1). The lateral flexion angle with respect to the absolute perpendicular of one sensor will be used to determine the trunk lateral flexion angle (T10). The average of the five angles for the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task will be calculated (cf. figure 3).

Heart rate and heart rate variability

HR, expressed in Hertz (Hz), will be continuously recorded using ECG, for which two electrodes will be placed ~5 cm cranial and ~3 cm left-lateral from the distal end of the sternum and over the anterior to mid-axillary line at the fifth left rib. Several HRV indices^{53–55} will be calculated from the ECG signal's time domain, including interbeat intervals (IBIs), SD of the IBIs (SDNN) and root mean squared successive differences between IBIs (RMSSD). All three HRV indices showed good reliability among smaller sample sizes (ICC over 0.7).⁵³ The median HR, IBI, SDNN and RMSSD for the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task will be calculated (cf. figure 3) as well as for the breaks to get an indication whether the active work break protocol has really been active compared with the passive work break protocol.

The signals of EMG, position sensors and ECG will be analysed and stored using a combined data analyser and logger (PS11-UD, THUMEDI GmbH & Co. KG, Thum, Germany). The EMG signals will be sampled at 4096 Hz with an overall common-mode rejection ratio of >96 dB, an overall effective sum of noise of <0.8 μ V, and will be

analysed in the frequency domain. The position sensors will be sampled at 4096 Hz with a resolution of 0.1° and maximal measurement error of 0.3° , and will be analysed in the time domain. The ECG signals will be sampled at 1000 Hz and analysed in the time domain.

Workload

After each experimental condition, participants will fill out the National Aeronautics and Space Administration Task Load Index (NASA-TLX) to assess mental demand, physical demand, temporal demand, own performance, effort and frustration on a scale from 0 to 100 for each of the six tasks performed.⁵⁶ The English version of the NASA-TLX has a high overall validity (0.86 Pearson correlation)⁵⁶ and excellent convergent validity with two other workload instruments (0.98 Pearson correlation)⁵⁷ and its German translated version has been validated and used in studies as well.^{58 59} The overall workload will be assessed by the unweighted average of all six dimensions and all six tasks,^{60 61} which may range between 0 (low subjective workload) and 100 (high subjective workload).

Subjective evaluation

After both intervention conditions, participants will fill out a self-developed questionnaire evaluating the conducted passive or active work breaks (see online supplemental material 4). The questionnaire contains seven questions: one about recovered body parts with multiple answer options; five about work break content, frequency, duration, performance and concentration using a five-point Likert scale; one about the likelihood of carrying out breaks on own initiative using a 100 mm VAS. Five-point and seven-point Likert scales showed to have comparable mean and variance values after rescaling.⁶² The reason that we used five-point Likert scales is because they would be generally better comprehensible and therefore more accurate,⁶³ valid and reliable^{64 65} when compared with more-point Likert scales. We decided to use a 100 mm VAS for evaluating how likely it is the surgeon will implement active or passive intraoperative work break, because the VAS applies a continuous response format, so that the surgeon is not restricted to a predetermined set of potential responses.⁶⁶ Although the 100 mm VAS has not been validated for the current evaluation question, it has shown excellent reliability (ICC 0.97) and good to excellent validity (Pearson correlation of 0.94 with 11-point NRS) when assessing musculoskeletal pain.⁵⁰

Statistical analysis

An overview of the primary and secondary outcomes is provided in table 2, including a description of the time points per outcome.

The primary outcome RPD and the secondary outcomes performance_{HOT_WIRE} and performance_{PEG} will be statistically tested using the generalised estimating equations (GEE)⁶⁷ with condition (three levels: no vs passive vs active work breaks) and time (two levels: $T_1/A_1/B_1$ vs $T_8/A_2/B_9$) as within-subject factors. For significant main

or interaction effects, we will perform post hoc pairwise comparisons using the Šidák correction.⁶⁸

The secondary outcomes RMS_{STATIC}, RMS_{MEDIAN}, RMS_{PEAK}, angle_{MEDIAN}, HR, IBI, SDNN and RMSSD will be analysed using the GEE with condition (three levels: no vs passive vs active work breaks) and time (six levels: $B_1, B_3, B_4, B_6, B_7, B_9$) as the within-subject factors. For significant main or interaction effects, we will perform post hoc pairwise comparisons using the Šidák correction. The secondary outcomes RMS_{SLOPE}, MPF_{SLOPE} and workload will be analysed using the GEE with condition (three levels: no vs passive vs active work breaks) as the within-subject factor. For significant main effects, we will perform post hoc pairwise comparisons using the Šidák correction. The six items of the evaluation questionnaire using a NRS or a VAS will be statistically tested using the GEE with condition (two levels: passive vs active work breaks) as the within-subject variable.

Although the order of conditions is randomised, we did not employ a full-factorial design, which means the order of the conditions (ie, order 1 to 6; cf. figure 1) will be included as a confounding variable in GEE.

The demographic outcomes as well as the one item of the evaluation questionnaire having multiple answer options will be analysed using descriptive statistics by presenting mean (SD) or median (IQR) according to the statistical distribution.

Subgroups analyses

This study is not designed to detect differences in potential subgroups within the study population. Therefore, we will follow an exploratory approach and be hypothesis generating rather than follow a confirmatory approach and be hypothesis testing. The aim of the exploratory subgroup analysis is to clarify potential heterogeneity of the effect of work breaks on the primary and secondary outcomes by splitting the participant data into subgroups.⁶⁹ We hereby take account of the lack of power to allow for significant results and rather use the results for future study data synthesis.⁷⁰ Although Burke *et al*⁷¹ recommended not carrying out more than two subgroup analyses because it increases the likelihood of finding false positives, we decided to carry out more since we follow an exploratory approach in order to generate further research hypotheses. There are several risk factors to be identified for subgroup analyses that have been shown to be associated with the occurrence of WRMSD,⁷² including working posture, work experience, age, gender, stressful working conditions, daily working hours and repetitive and forceful movements. From these risk factors, we considered gender and age as relevant indicators for our exploratory subgroup analyses for their potential influence on the effect of the intervention (ie, work breaks) on the study outcomes. We complemented the subgroup analyses with selected items of the NASA-TLX.

► Gender: male versus female.

- The literature is not unanimous as to whether gender plays a significant role as a risk factor for

Table 2 Description of the dependent variables (outcomes) that will be statistically tested

Domain	Outcome	Calculation	Unit
Primary outcome			
Rating of perceived discomfort	RPD	Rating at time points T_2 and T_7	(0–10)
Secondary outcomes			
Performance	Performance _{HOT_WIRE}	Relative time the ring did not touch the wire before (A_1) and after (A_2) each condition	(%)
	Performance _{PEG}	Number of transferred pegs / 60s in the first (B_1) and ninth (B_9) peg-transfer task	(#)
Muscular activity	RMS _{STATIC} *	10th percentile muscle activity in the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(%MVE)
	RMS _{MEDIAN} *	50th percentile muscle activity in the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(%MVE)
	RMS _{PEAK} *	90th percentile muscle activity in the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(%MVE)
Muscular fatigue	RMS _{SLOPE} *	Slope using the median RMS of the third (B_3), sixth (B_6) and ninth (B_9) peg-transfer task	(%MVE/min)
	MPF _{SLOPE} *	Slope using the MPF of the third (B_3), sixth (B_6) and ninth (B_9) peg-transfer task	(Hz/min)
Upper body posture	Angle _{MEDIAN} †	Median angle during the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(°)
Heart rate	HR	Median HR during the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(Hz)
Heart rate variability	IBI	Median IBI during the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(ms)
	SDNN	Median SDNN during the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(ms)
	RMSSD	Median RMSSD during the first (B_1), third (B_3), fourth (B_4), sixth (B_6), seventh (B_7) and ninth (B_9) peg-transfer task	(ms)
Workload	Workload	Unweighted average over all tasks and domains	(0–100)

Symbols used in the description of the calculation-column (ie, T_1 , T_6 , B_1 , B_3 , B_4 , B_6 , B_7 , B_9) are indicated in figure 3.

*The seven muscles are as follows: erector spinae left and right, trapezius descendens left and right, deltoid medialis right, extensor digitorum right, flexor carpi radialis right.

†This outcome is tested for five angles: cervical lordosis, thoracic kyphosis, lumbar lordosis, neck lateral flexion, trunk lateral flexion. HR, heart rate; IBI, interbeat interval; MPF, median power frequency; RMS, root mean square; RPD, rating of perceived discomfort.

the development of WRMSD. Some studies show a significant association between gender and WRMSD,^{72–74} whereas others do not,⁷⁵ although the vulnerability varies between men and women depending on the affected body site.^{74 76}

- Age: study population divided into two groups based on the median of the overall study population (ie, group 1: ≤median; group 2: >median).
 - Recent reports and studies highlight the increasing prevalence of WRMSD with increasing age⁷⁷ and some even show a significant association between age and prevalence of WRMSD.^{75 76 78}
- Previous or current episodes of musculoskeletal symptoms: study population divided into two groups based on whether participants at any time in their life had any ache, discomfort or pain in one or more body areas (question as part of the NMQ; that is, group 1: yes; group 2: no).

- A recent study among nursing personnel showed that a previous episode of low back pain (LBP) was associated (OR of 4.31) with disabling LBP.⁷⁹

Dealing with missing data

In case of missing data in the performance, muscle activity, postural and HR data, the missing value will not be filled. In case of the NASA-TLX items, missing values will be filled using the single imputation method of the most frequent value.⁸⁰ Although this simple technique is likely to cause biased overall estimates,^{81 82} we consider this likelihood small, since we check this NASA-TLX questionnaire directly after completion.

Data management and confidentiality

The physical collected and digitally recorded data will be numerically pseudonymised by assigning a randomly generated, two-digit identification number to the

examined participant to maintain confidentiality. The physical collected data forms will be stored in locked cabinets of the institute of occupational and social medicine and health services research (IASV) in areas with limited access. The digitally recorded data will be saved on a separate server of the IASV. A decoding list together with written informed consent forms of the participants will be stored in separate locked cabinets of the IASV in areas with limited access. Only the principal investigator (TL) and some other researchers (BS, MAR) directly involved in the study can get permission to access the decoding list and the physical and digital data.

All data will be stored for a period of 10 years after publication of the study results. After 10 years, the destruction of the data in paper form is carried out by means of the disposal boxes for data protection at the UKT, and the destruction of the data in electronic form is carried out by means of transferring the data off the memory cards of the devices (ie, measurement equipment, laptops and personal computers).

Data monitoring and quality assurance

The progress of the study will be monitored by the principal investigator (TL), who is also responsible for reporting to the (preliminary) data to the main collaborator, the DOG of the UKT.

The occurrence of adverse events that could be related to the work-break intervention will be monitored and assessed by the researcher that is present during the laparoscopic simulations at the laboratory. Related to the intervention are those adverse events that occur after the participant started to receive the study intervention. The expectation that adverse events occur is very small; therefore, harms will be part of routine monitoring and not categorised as primary or secondary outcome.

Safety standards of the devices and measurement equipment that will be used are documented in declarations of conformity that were received at the time of purchase of the devices and equipment.

Patient and public involvement

Patients and the public were not involved in the design, or conduct, or reporting, or dissemination plans of this trial.

ETHICS AND DISSEMINATION

Research ethical approval

The study and all study-related documents were designed following the principles formulated in the current version of the Declaration of Helsinki.⁸³ A final approval of the study design including suggested amendments by the responsible local ethical committee (no 618/2018BO2) of the Medical Faculty of the University and UKT was received in February 2019 (see online supplemental material 5).

Dissemination

Abstracts of the study protocol and (preliminary) study results may be submitted for a presentation to relevant

scientific symposia and conferences in the field of occupational ergonomics and human factors, which can be either local (Research Colloquium of the Medical Faculty of Tübingen), national (GfA, DGAUM, FAP) or international (PREMUS, IEA, ICOH). The study will result in three results papers that will be submitted to, for example, one of the following international, peer-reviewed journals: *Annals of Surgery*, *Surgical Endoscopy*, and *International Journal of Surgery*. In case subjects wish to be informed about the results of the study, they will receive the primary outcome paper by email.

Acknowledgements The authors would like to thank physiotherapist Georg Haupt for his support in developing the exercise protocol for the active work breaks and Nadine Badie, Julia Gabriel and Xaver Thalhofer for their support in data collection. The study protocol has been presented as a poster at an international conference (PREMUS 2019, Bologna, Italy) and as a presentation at a national conference (GfA 2020, Berlin, Germany).

Contributors Principal investigator of the study is TL. The idea and concept of the study were developed by TL, BS and MAR. Preparation of the simulation material was all prepared by RS and RB. TL drafted this study protocol and all other authors (BS, MAR, RS, BK, RB) revised the manuscript and approved the final version. TL and RB will be involved in the data collection. TL will be responsible for the data analysis and for writing the findings in consequent results manuscripts.

Funding This work was partially supported by a personal intramural fortune grant (TL) from the Junior Academy of the Faculty of Medicine of the University of Tübingen (Germany), with grant number (2480-1-0). The remainder of the work of the Institute of Occupational and Social Medicine and Health Services Research was financially supported by an unrestricted grant of the employers association of the metal and electrical industry Baden-Württemberg (Südwestmetall; grant number N/A).

Competing interests None declared.

Patient and public involvement statement Patients and the public were not involved in the design, or conduct, or reporting, or dissemination plans of this trial.

Patient consent for publication Not required.

Provenance and peer review Not commissioned; externally peer reviewed.
