ABSTRACT

Purpose The optimum systemic therapies for advanced/metastatic renal cell carcinoma (RCC) of favourable, intermediate and poor risk have not been established. We aimed to compare and rank the effects associated with systemic therapies in the first-line setting.

Methods We searched PubMed, Cochrane databases, Web of Science and ClinicalTrials.gov for randomised controlled trials (RCT) published up to February 2020 of all available treatments for advanced/metastatic RCC. Analysis was done on a Bayesian framework.

Results 15 unique RCTs including 8995 patients were identified. For advanced/metastatic RCC of favourable risk, avelumab plus axitinib was associated with a significantly higher improvement in progression-free survival (PFS) than sunitinib (HR 0.57, 95% CI 0.34 to 0.96). For intermediate-risk patients, cabozantinib, nivolumab plus ipilimumab, pembrolizumab plus axitinib and avelumab plus axitinib were associated with significantly higher improvement in PFS than sunitinib (HR 0.63, 95% CI 0.44 to 0.97; HR 0.66, 95% CI 0.53 to 0.81; HR 0.58, 95% CI 0.44 to 0.80; HR 0.62, 95% CI 0.47 to 0.83, respectively); pembrolizumab plus axitinib and nivolumab plus ipilimumab were associated with significantly higher improvement in overall survival (OS) than sunitinib (HR 0.53, 95% CI 0.34 to 0.81; HR 0.66, 95% CI 0.50 to 0.87, respectively). For poor-risk patients, nivolumab plus ipilimumab and pembrolizumab plus axitinib were associated with significantly higher improvement in PFS than sunitinib (HR 0.57, 95% CI 0.43 to 0.76; HR 0.48, 95% CI 0.30 to 0.82, respectively); nivolumab plus ipilimumab and pembrolizumab plus axitinib were significantly more efficacious for OS than sunitinib (HR 0.57, 95% CI 0.39 to 0.883; HR 0.43, 95% CI 0.23 to 0.80, respectively). For OS, there were 81% and 78% probabilities that pembrolizumab plus axitinib was the best option for intermediate-risk and poor-risk patients, respectively.

Conclusion Avelumab plus axitinib might be the optimum treatment for advanced/metastatic RCC of favourable risk. Pembrolizumab plus axitinib might be the optimum treatment for intermediate-risk and poor-risk patients.

Strengths and limitations of this study

- This is the first network analysis to compare systemic treatments for advanced/metastatic renal cell carcinoma separately by risk groups.
- Various statistical models were applied to synthesise data. The reliability and accuracy of results were corroborated by the low statistical heterogeneity and excellent model fit.
- Assessment of both efficacy and adverse events provides new insights into the benefit-harm balance of different systemic treatments.
- Main limitation lies in the reporting quality of trials included.

INTRODUCTION

Renal cell carcinoma (RCC) comprises approximately 90% of renal cancer, and represents approximately 2%–3% of all new cancers worldwide.¹ It was estimated that there would be 62 700 new cases of renal cancer and 14 240 renal cancer-related deaths in the USA in 2016.² In the European Union, new renal cancer cases and deaths in 2012 were approximately 84 400 and 34 700, respectively.³ Up to 30% of patients were presented with advanced/metastatic RCC at the time of initial diagnosis.^{4 5} Advanced/metastatic RCC is not a single condition, but is actually a heterogeneous group of conditions with different prognosis. The most widely accepted prognostic model is from the Memorial Sloan Kettering Cancer Center (MSKCC) and stratifies patients into favourable, intermediate and poor-risk groups depending on the existence of well-characterised laboratory and clinical risk factors. The 2-year survival rates were 45%, 17% and 3% for favourable, intermediate and poor-risk groups, respectively.⁶ In this systematic review, we focus

on favourable, intermediate and poor-risk patients with advanced/metastatic RCC.

In recent years, systemic treatment for advanced/metastatic RCC has changed from cytokines to drugs targeting angiogenesis. In 2007, results from two randomised controlled trials (RCT) have been published reporting progression-free survival (PFS) improvement of two newer targeted agents (sunitinib and sorafenib).^{7 8} To date, eight targeted drugs have been approved for treating advanced/metastatic RCC both in the USA and Europe: five tyrosine kinase inhibitors (TKI): sunitinib, sorafenib, pazopanib, cabozantinib and axitinib; two mammalian target of rapamycin (mTOR) complex 1 kinase inhibitors: temsirolimus and everolimus; and the recombinant humanised anti-vascular endothelial growth factor (VEGF) monoclonal antibody bevacizumab combined with interferon- α (IFN- α). All eight targeted drugs showed significant survival benefit in randomised trials and established a prominent role in treating advanced/metastatic RCC.^{7 9-15} More recently, immune checkpoint antibodies have introduced a new treatment option. CheckMate 214 reported that nivolumab plus ipilimumab was associated with a significantly higher overall survival (OS) than sunitinib in the first-line setting.¹⁶ To further improve their efficacy, the combination of different classes of agents is currently evaluated in clinical trials.¹⁷⁻²⁰ However, there are insufficient head-to-head RCTs to directly investigate the comparative effectiveness of all available therapies. Given the variety of treatment options for patients with advanced/metastatic RCC and the limited evidence regarding the optimum treatment strategy, it is a challenge for clinicians to make the best decision.

In the present study, we performed a Bayesian network meta-analysis to compare first-line systemic treatments for advanced/metastatic RCC of favourable, intermediate and poor risk, respectively. Network meta-analysis enables indirect comparisons based on a common comparator treatment when a head-to-head trial is unavailable and integrates direct and indirect comparisons to compare several treatment strategies while fully respecting randomisation.^{21 22} We aimed to summarise and compare the efficacy and safety associated with currently available systemic therapies for treating advanced/metastatic RCC of different risk categories using network meta-analysis.

METHODS

Literature search strategy

A comprehensive literature search was performed in PubMed, Web of Science, ClinicalTrials.gov and Cochrane databases for RCTs of systemic therapies of advanced/metastatic RCC (see online supplementary appendix for all search terms). All the reference lists of identified trials and related reviews were examined to find potential trials. The search was conducted in February 2020. There were no publication date or language restrictions.

Inclusion and exclusion criteria

All studies were selected according to the search strategy based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses criteria.²³ Studies were included if they satisfied three criteria: (1) the study enrolled patients who had histologically or cytologically confirmed advanced/metastatic RCC of favourable, intermediate or poor risk; (2) patients were randomly assigned to receive systemic therapies alone or in combination. Relevant interventions included, but were not restricted to: sorafenib, sunitinib, pazopanib, cabozantinib, nivolumab, ipilimumab, axitinib, tivozanib, everolimus, temsirolimus, or bevacizumab plus IFN- α . Previous systemic therapy for advanced/metastatic RCC was not allowed; (3) one or more of the outcomes of interest mentioned below were reported. Non-original articles, duplicate reports and non-RCTs were excluded.

Data extraction and quality assessment

Two researchers (GC and XiW) examined the manuscripts of included trials independently, and extracted data into a structured form, including patient characteristics, treatment strategies and interest outcomes (PFS, OS, high-grade (grade ≥ 3) and overall drug-related adverse events (AE)). The patient characteristics, treatment strategies, PFS and OS were extracted at the study level for meta-analyses even if the patient level were available. For drug-related AEs, the patient-level data were extracted for meta-analyses. We gave priority to extracting data from intention-to-treat analyses. The methodological quality of included RCTs was assessed using the Cochrane risk of bias assessment tool.²⁴ Disagreement between investigators was resolved by consensus.

Data synthesis and analysis

First, we performed traditional meta-analyses to compare the treatments using Stata V.12 (StataCorp, College Station, TX, USA). We applied the χ^2 test and the I^2 statistic to investigate the possibility of heterogeneity among studies. A p value < 0.10 or an $I^2 > 50\%$ suggested the presence of substantial heterogeneity.

Second, we did Bayesian network meta-analyses. For meta-analysis of PFS and OS, the reported adjusted HRs with 95% CIs were applied as the outcome measure. For studies not reporting HRs, we calculated them from Kaplan-Meier curve and information on follow-up with the pragmatic approach reported by Tierney *et al.*²⁵ For drug-related AEs, we calculated ORs using the available patient-level data abstracted from the trials. Both random effects and fixed effects models were performed for all Bayesian network meta-analyses.²⁶ Goodness of model fit was assessed using the deviance information criterion and between-study SD.^{26 27} Convergence was determined graphically according to the method described by Gelman and Rubin.²⁸

It is believed that certain systemic treatments are effective in certain risk groups than others, for example, sunitinib is more effective in favourable-risk patients and

nivolumab plus ipilimumab is more effective in intermediate and poor-risk patients,²⁹ suggesting that there is a treatment-by-risk group (favourable, intermediate and poor-risk groups) interaction. Taking no account of this possible interaction in the analysis, transitivity assumption across all included trials would be violated. Therefore, we performed all network analyses separately by risk groups (favourable, intermediate and poor-risk groups) according to the MSKCC or International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk model to assure transitivity assumption.

One key assumption for network analysis is that direct and indirect comparisons do not disagree beyond chance.^{26 30} To explore for evidence of inconsistency in the network, investigators compared the estimated treatment effects from the entire network with traditional pairwise estimates.³⁰ Sensitivity analyses were performed restricted to trials that assessed approved systemic therapies (sunitinib, sorafenib, pazopanib, cabozantinib, axitinib, everolimus, temsirolimus, bevacizumab plus IFN- α and nivolumab plus ipilimumab). Publication bias and small-study effects were assessed using funnel plots.³¹

We performed the Bayesian network analysis using OpenBUGS V.3.2.2 for PFS, and Gemtc V.0.14.3 (van Valkenhoef *et al.*,³²) for AEs. We performed fewer iterations for PFS to reduce computational burden without loss of convergence and model fit. For PFS, we applied 15 000 iterations obtained after a training phase of 10 000 iterations. In order to minimise autocorrelation, we applied a thinning interval of 50 for each chain. For AEs, we applied the 60 000 iterations after a training phase of 40 000 iterations. The treatments were ranked in terms of PFS, OS and high-grade AEs, respectively, using the surface under the cumulative ranking curve (SUCRA) and the distribution of the ranking probabilities.³³

Patient and public involvement

Patients and/or the public were not involved in the design, or conduct, or reporting, or dissemination plans of this research.

RESULTS

Search results and study characteristics

The literature search yielded 2017 potentially eligible studies, of which 1873 were excluded based on screening titles and abstracts (figure 1). The full texts of 144 remaining studies were analysed, and finally 21 publications reporting 15 unique RCTs were included (table 1), involving 8995 participants randomly assigned to one of the 13 treatment strategies: sorafenib, sunitinib, pazopanib, cabozantinib, nivolumab plus ipilimumab, axitinib, tivozanib, everolimus, IFN- α , bevacizumab plus IFN- α , temsirolimus plus bevacizumab, avelumab plus axitinib, and pembrolizumab and axitinib. According to the MSKCC or IMDC criteria, there were 2783, 5474 and

Figure 1 Literature search and selection. RCC, renal cell carcinoma.

721 participants who had favourable, intermediate and poor-risk disease, respectively.

The main characteristics of included RCTs are summarised in table 1. The demographic characteristics of patients were well balanced across trials. Enrolled patients across trials were similar in terms of age, gender and risk classification. Across trials, the median age of patients ranged from 58 to 64 years. The participants were predominantly male (71.7%, 6451 of 8995). The included trials were designed similarly. Median follow-up ranged from 10.7 to 58 months. The mean sample sizes were 100, 192 and 32 patients per group for favourable, intermediate and poor-risk subtypes, respectively. Thirteen trials selected for clear-cell carcinoma subtypes,^{10–12 15 16 34–41} and two trials also included small subsets of non-clear-cell histotypes, each comprising 11% and 14% of the study population, respectively.^{42 43} All studies were two-arm trials. The dosages used in most of the trials were within the recommended dose ranges.

In this network meta-analysis, results are reported based on fixed effects models because they demonstrated better goodness of fit compared with random effects models. The results of random effects models are available in online supplementary appendix tables 1–5.

Progression-free survival

For advanced/metastatic RCC of favourable risk, 13 trials enrolling 2514 total patients reported adequate information on PFS and contributed to network meta-analysis

Figure 2 Analysis of progression-free survival for patients with favourable-risk disease. (A) Network diagram: the size of every treatment node corresponds to the number of randomly assigned patients. The width of the lines is proportional to the number of trials. (B) Forest plot, with sunitinib as the comparator. (C) Ranking of treatments. Rankograms were drawn according to distribution of the ranking probabilities. Ranking indicates the probability to be the best treatment, the second best, the third best, and so on, in terms of progression-free survival (PFS), among the 13 treatments. Numbers in parentheses indicate 95% credible intervals. AVE_AXI, avelumab plus axitinib; AXI, axitinib; BEV_IFN, bevacizumab plus interferon; EVE, everolimus; IFN, interferon; NIV_IPI, nivolumab plus ipilimumab; PAZ, pazopanib; PEM_AXI, pembrolizumab plus axitinib; PLA, placebo; SOR, sorafenib; SUN, sunitinib; TEM_BEV, temsirolimus plus bevacizumab; TIV, tivozanib.

(figure 2A).^{10–13 15 16 35–38 40–43} Figure 2B summarises the results of the network meta-analysis for PFS. Compared with sunitinib, IFN- α and nivolumab plus ipilimumab were associated with significantly worse PFS (HR 2.69, 95% CI 1.54 to 4.67 and HR 2.18, 95% CI 1.47 to 3.25, respectively). Network meta-analysis showed that only avelumab plus axitinib was associated with a significantly higher improvement in PFS than sunitinib (HR 0.57, 95% CI 0.34 to 0.96). Based on the results of ranking,

Figure 3 Analysis of progression-free survival for patients with intermediate-risk disease. (A) Network diagram. (B) Forest plot, with sunitinib as the comparator. (C) Ranking of treatments. Numbers in parentheses indicate 95% credible intervals. AVE_AXI, avelumab plus axitinib; AXI, axitinib; BEV_IFN, bevacizumab plus interferon; CAB, cabozantinib; EVE, everolimus; IFN, interferon; NIV_IPI, nivolumab plus ipilimumab; PAZ, pazopanib; PEM_AXI, pembrolizumab plus axitinib; PLA, placebo; SOR, sorafenib; SUN, sunitinib; TEM_BEV, temsirolimus plus bevacizumab; TIV, tivozanib.

there was a 45% chance that avelumab plus axitinib provided the greatest PFS benefit for patients with favourable-risk disease (SUCRA=92.3%) (figure 2C).

For advanced/metastatic RCC of intermediate risk, 14 trials enrolling 5473 total patients contributed to the analysis of PFS (figure 3A).^{10–13 15 16 34–38 40 41 43} Network meta-analysis demonstrated that cabozantinib, nivolumab plus ipilimumab, pembrolizumab plus axitinib and avelumab plus axitinib were associated with significantly higher improvement in PFS than sunitinib (HR 0.63, 95% CI 0.44 to 0.97; HR 0.66, 95% CI 0.53 to 0.81; HR 0.58, 95% CI 0.44 to 0.80; HR 0.62, 95% CI 0.47 to 0.83, respectively). Everolimus, bevacizumab plus IFN- α and temsirolimus plus bevacizumab

Figure 4 Analysis of progression-free survival for patients with poor-risk disease. (A) Network diagram. (B) Forest plot, with sunitinib as the comparator. (C) Ranking of treatments. Numbers in parentheses indicate 95% credible intervals. AVE_AXI, avelumab plus axitinib; BEV_IFN, bevacizumab plus interferon; CAB, cabozantinib; EVE, everolimus; IFN, interferon; NIV_IPI, nivolumab plus ipilimumab; PEM_AXI, pembrolizumab plus axitinib; SUN, sunitinib; TEM_BEV, temsirolimus plus bevacizumab.

were significantly less efficacious for PFS than sunitinib (HR 1.50, 95% CI 1.11 to 2.01; HR 1.69, 95% CI 1.18 to 2.41; HR 1.88, 95% CI 1.22 to 2.81, respectively) (figure 3B). Based on the analysis of ranking, pembrolizumab plus axitinib had the highest probability (49%) to be the best treatment for intermediate-risk patients (SUCRA=90.7%). Avelumab plus axitinib and cabozantinib had a similar likelihood of being the second-best option for patients with intermediate-risk disease (figure 3C).

Based on data that were available for advanced/metastatic RCC of poor risk, the network involved seven trials comparing nine different treatments (721 total patients; figure 4A).^{15 16 34–36 38 40 41 43} Network meta-analysis demonstrated that nivolumab plus ipilimumab and pembrolizumab plus axitinib were associated with significantly higher improvement in PFS than sunitinib (HR 0.57, 95% CI 0.43 to 0.76; HR 0.48, 95% CI 0.30 to

Figure 5 Analysis of overall survival for patients with favourable risk (A), intermediate risk (B) and poor risk (C). Numbers in parentheses indicate 95% credible intervals. NIV_IPI, nivolumab plus ipilimumab; PAZ, pazopanib; PEM_AXI, pembrolizumab plus axitinib; SUN, sunitinib.

0.82, respectively) (figure 4B). On the base of ranking analysis, there was a 60% probability that pembrolizumab plus axitinib had the greatest PFS for poor-risk patients (SUCRA=91.3%) (figure 4C).

Overall survival

Five RCTs reported OS according to risk subgroups, and data from three of them contributed to the network meta-analysis (572, 1801 and 407 patients for favourable, intermediate and poor risk, respectively).^{16 39 40} For advanced/metastatic RCC of favourable risk, there is no significant OS benefit between sunitinib and pazopanib (HR 0.88, 95% CI 0.64 to 1.21) or pembrolizumab plus axitinib (HR 0.64, 95% CI 0.24 to 1.70) (figure 5A). For intermediate-risk patients, pembrolizumab plus axitinib and nivolumab plus ipilimumab were associated with significantly higher improvement in OS than sunitinib (HR 0.53, 95% CI 0.34 to 0.81; HR 0.66, 95% CI 0.50 to 0.87, respectively) (figure 5B). For advanced/metastatic RCC of poor risk, pembrolizumab plus axitinib and nivolumab plus ipilimumab were significantly more efficacious for OS than sunitinib (HR 0.43, 95% CI 0.23 to 0.80; HR 0.57, 95% CI 0.39 to 0.83, respectively) (figure 5C). Based on the results of ranking, there were 81% and 78% probabilities for pembrolizumab plus axitinib to be the best choice for intermediate and poor-risk patients, respectively (SUCRA=93.1% and SUCRA=91.4%, respectively) (online supplementary appendix figures 1–3).

Adverse events

Nine trials contributed to our analysis of overall and high-grade drug-related AEs.^{10 11 13 15 16 37 40–42} All the nine trials did not provide AE data for different risk groups, so we extracted a summary of AE data. Results of comparisons of

Figure 6 Pooled ORs for high-grade adverse events. The column treatment is compared with the row treatment. ORs lower than 1 favour the column-defining treatment. Numbers in parentheses indicate 95% credible intervals. Stepwise comparison of treatments did not find significant differences in rates of high-grade adverse events. AVE_AXI, avelumab plus axitinib; CAB, cabozantinib; NIV_IPI, nivolumab plus ipilimumab; PAZ, pazopanib; PEM_AXI, pembrolizumab plus axitinib; PLA, placebo; SOR, sorafenib; SOR_IL-2, sorafenib plus interleukin-2; SUN, sunitinib; TIV, tivozanib.

AEs of nine systemic treatments are presented in [figure 6](#) and online supplementary appendix figure 4. Stepwise comparison of all the seven therapies did not find significant differences in rates of high-grade or overall AEs. The most common AEs included diarrhoea, hypertension, fatigue and decreased appetite.

Network assumptions, sensitivity analysis, publication bias and risk of bias

Consistencies between direct and indirect evidence were noted for any comparisons (online supplementary appendix figure 5 and online supplementary appendix tables 1–5). Results from the sensitivity analyses were in line with the primary analysis (online supplementary appendix table 6). The comparison-adjusted funnel plot ([figure 7](#)) for PFS was largely symmetric, indicating no obvious small-study effects and publication bias. The methodological quality was moderate in the included studies (online supplementary appendix figure 6). All trials were thought to have low risk of bias for random sequence generation, incomplete outcome data and selective reporting of outcomes. Ten trials had evidence of high risk of bias for masking. ^{12 13 15 36–38 40–43}

DISCUSSION

Our network meta-analysis of 15 RCTs including 8995 individuals assessed the efficacy and safety of all major systemic therapies for the treatment of advanced/metastatic RCC in the first-line setting. Findings of this meta-analysis might help choose among systemic agents for the management of patients with previously untreated advanced/metastatic RCC. In terms of PFS, avelumab plus axitinib was most likely to be the best treatment regimen for advanced/metastatic RCC of favourable risk, and pembrolizumab plus axitinib seemed to be the most

efficacious treatment strategy for patients with intermediate and poor risk. In terms of OS, there were no significant differences among systemic therapies for advanced/metastatic RCC of favourable risk, and pembrolizumab plus axitinib was probably to be the best option for patients with intermediate and poor risk. In terms of drug-related AEs, there were no significant differences among systemic therapies.

In RCC with clear-cell subtype, hypoxia-inducible factor (HIF) accumulation due to loss of von Hippel-Lindau leads to overexpression of VEGF and platelet-derived growth factor (PDGF), which promotes tumour

Figure 7 Funnel plot of randomised controlled trials included in the meta-analysis for HRs of progression-free survival. angiogenesis.^{44 45} This process substantially makes a contribution to the development and progression of clear-cell RCC. Inhibiting the VEGF signalling has been supposed as the key mechanism for antitumour effects in clear-cell RCC. To date, eight targeted drugs have been approved for treating advanced RCC: sunitinib, sorafenib, pazopanib, cabozantinib, axitinib, everolimus, temsirolimus and bevacizumab (in combination with IFN- α).

As shown in this analysis, for patients with intermediate risk, sunitinib resulted in a significant PFS benefit compared with everolimus. The varied clinical benefit could be associated with mechanisms of action of TKI and mTOR inhibitor. Sunitinib inhibits VEGF receptors 1, 2 and 3, which may be the most clearly relevant targets in RCC so far, and exhibits potent activity against PDGF receptor.^{11 46} It has been reported that PDGF plays a critical role in the recruitment of pericytes to sprouting tumour vessels, and pericyte-covered vessels are more likely resistant to antivasculature therapy than those pericyte-negative vessels.^{47 48} The mTOR complex is the upstream of an intracellular signalling network regulating cell growth and angiogenesis, and it plays a key role in the pathogenesis of advanced/metastatic RCC.⁴⁹ It has been demonstrated that rapamycin analogues, including everolimus and temsirolimus, inhibit only one of two signalling complexes of mTOR.⁵⁰ The mTORC1 signalling is potently inhibited by everolimus and temsirolimus, while the mTORC2 signalling is not.⁵¹ Consequently, one downstream signalling of mTOR activation is unopposed. The relatively unsatisfactory efficacy should disable the mTOR inhibitors as more suitable therapies for the treatment of advanced/metastatic RCC than TKIs. Regarding TKIs, our results suggest that sunitinib was most likely to be the best treatment regimen for patients with favourable-risk disease.

A potentially additive benefit from combinations of targeted drugs has been suggested on the basis that they inhibit separate cellular pathways. However, our results show that temsirolimus plus bevacizumab and bevacizumab plus IFN- α provide little survival benefit compared with sunitinib, further confirming absence of evidence that combination treatment simultaneously inhibiting both VEGF and mTOR signalling results in therapeutic synergy.^{18 20 38}

Immune checkpoint antibodies block the inhibitory T-cell receptor programmed death-1 (PD-1) or cytotoxic T-lymphocyte antigen 4 (CTLA-4) signalling to augment tumour-specific immune response.⁵² Nivolumab (an anti-PD-1 antibody) is approved for the treatment of advanced RCC in the second-line setting. Ipilimumab (an anti-CTLA-4 antibody) is approved for the treatment of advanced melanoma. Nivolumab plus ipilimumab has been reported to have significant efficacy in multiple tumour types.^{53 54} In this analysis, pembrolizumab plus axitinib appeared to be the optimum treatment for intermediate and poor-risk patients. Single-agent antitumour activity of pembrolizumab and axitinib for mRCC has been reported in previous studies.^{12 55} Accordingly, axitinib in combination with pembrolizumab was assessed and contributed to objective response rate in 73% of

patients in a phase 1b trial.⁵⁶ Our result was in consistent with results of KEYNOTE-426 trial, demonstrating that pembrolizumab plus axitinib resulted in significant OS and PFS benefit compared with sunitinib.⁴⁰ In addition, the survival benefit of pembrolizumab plus axitinib was observed independent of PD-L1 status.⁴⁰

Pembrolizumab plus axitinib is a combination of anti-PD-1 monoclonal antibody and VEGF receptor TKI. Immune checkpoint inhibitors (ICI) block the inhibitory T-cell receptor PD-1 or CTLA-4 signalling to augment tumour-specific immune response.⁵² Besides antiangiogenic effects, VEGF inhibition could enhance the recruitment and infiltration of immune cells into the tumours.^{57 58} It was reported that simultaneous blockade of PD-1 and VEGF receptor-2 induced decreased tumour neovascularisation and tumour inhibition in a murine model.⁵⁹ These studies suggested that the combination of ICI and VEGF receptor inhibitors could provide enhanced benefit for mRCC. Recently, in addition to pembrolizumab plus axitinib, avelumab (anti-PD-L1 antibody) plus axitinib and atezolizumab (anti-PD-L1 antibody) plus bevacizumab were respectively assessed in two phase 3 RCTs (IMmotion 151 and JAVELIN Renal 101), and both of them showed significant survival benefit for mRCC compared with sunitinib.^{40 60} However, there is no head-to-head trial comparing combinations of ICI and VEGF receptor inhibitors (pembrolizumab plus axitinib, avelumab plus axitinib and atezolizumab plus bevacizumab) directly. Consistent with our previous study, the present analysis revealed that pembrolizumab plus axitinib presented the highest OS benefit for intermediate and poor-risk patients. For advanced/metastatic RCC of favourable risk, only avelumab plus axitinib was associated with a significantly higher improvement in PFS than sunitinib, suggesting avelumab plus axitinib might be the optimum treatment for favourable-risk patients. Considering patients continued to be followed for OS in the JAVELIN Renal 101 trial,⁴¹ the real OS benefit for avelumab plus axitinib over sunitinib requires additional follow-up.

Recently, several network meta-analyses were attempted to investigate the comparative effects of different systemic agents for treatment of advanced/metastatic RCC.^{61–64} However, trials included in the meta-analyses enrolled patients with different risk groups. The analysis used aggregate data and did not perform subgroup analysis based on risk strata. In the present study, we performed a network meta-analysis to compare first-line systemic treatments for advanced/metastatic RCC of favourable, intermediate and poor risk, respectively, thus providing physicians with the optimal treatment for different risk groups.

The strengths of our study are as follows. To the best of our knowledge, this study is the first network analysis to compare systemic treatments for advanced/metastatic RCC separately by risk groups. We applied multiple rigorous search strategies to retrieve all potentially eligible RCTs. In the present study, we comprehensively compared and ranked all available first-line systemic therapies for advanced/metastatic RCC of favourable, intermediate and poor risk, respectively, thus providing

physicians with an overall appraisal of systemic therapies for different risk groups. In addition, we used Bayesian network meta-analysis to synthesise data. This approach provides indirect effect estimates in the absence of head-to-head trial and incorporates all available information from RCTs while fully maintaining randomisation.^{21 22} We applied various statistical models to increase reliability of the results. Results were consistent across all analysed outcomes. Moreover, the reliability and accuracy of results were corroborated by the low statistical heterogeneity and excellent model fit. Finally, assessment of both efficacy and AEs provides new insights into the benefit-harm balance of different systemic treatments.

However, the limitations of our study must be taken into account. The major limitation of this network meta-analysis lies in the reporting quality of trials reviewed. Ten included trials were not masked, which might affect the validity of our findings. In addition, three included trials (CABOSUN, ROSORC and RECORD-3) are phase 2 RCTs with smaller sample size, and they may be less authoritative compared with phase 3 RCTs. Moreover, most of the trials did not perform the analysis of OS in risk subgroups, which made it impossible to assess the OS benefits of all the existing treatments for different risk patients. In addition, this meta-analysis was conducted based on summary statistics rather than individual patient-level data. There might be some confounding factors (eg, ethnic origin, prior nephrectomy, and so on) at the individual patient level that might influence the benefit of systemic treatments, but were not available; therefore analyses adjusted for these factors were impossible in our network meta-analysis. Access to patient-level longitudinal data would allow us to establish more robust and accurate conclusions in specific subgroups of patients. Moreover, the length of follow-up varied across studies, resulting in potential variations in survival benefits and AEs. Due to only eight trials reporting median follow-up, sensitivity analyses adjusted for this factor were impossible. Moreover, individual dosage varied across studies and data were too sparse to investigate the effects of different schedules, which might somewhat affect the generalisability of our findings. Since the analysis was based on highly selected RCTs and the results were based on fixed effects models, findings in this analysis may not be entirely generalised to real-world practice. Finally, findings in this meta-analysis were mainly based on patients with clear-cell advanced RCC, thus no robust recommendations can be provided for non-clear-cell subtypes. Two trials included small subsets of non-clear-cell histotypes (11% and 14% of the study population), which might somewhat damage the results of our analysis.

CONCLUSIONS

Our network meta-analysis suggested that: avelumab plus axitinib might be the optimum treatment for advanced/metastatic RCC of favourable risk; pembrolizumab plus axitinib was most likely to be the best option

for intermediate and poor-risk patients. Further well-designed, large-scale RCTs are required to confirm and update the findings of this analysis.

Contributors GC and XiW conceived and designed the meta-analysis. ZW and XT identified and acquired the reports of trials, and extracted the data. XuW and HZ analysed and interpreted the data. CZ and GJ contacted the authors of the trials for additional information. GC and XiW drafted the manuscript. TY critically reviewed the manuscript. All authors approved the final submitted version of the report.
