ABSTRACT

Objectives This systematic review aimed to assess the role of physician's sex and gender in relation to processes of care and/or clinical outcomes within the context of cardiac operative care.

Design A systematic review.

Data sources Searches were conducted in PsycINFO, Embase and Medline from inception to 6 September 2018. The reference lists of relevant systematic reviews and included studies were also searched.

Eligibility criteria for selecting studies Quantitative studies of any design were included if they were published in English or French, involved patients of any age undergoing a cardiac surgical procedure and specifically assessed differences in processes of care or clinical patient outcomes by physician's sex or gender. Studies were screened in duplicate by two pairs of independent reviewers.

Outcome measures Processes of care, patient morbidity and patient mortality.

Results The search yielded 2095 publications after duplicate removal, of which two were ultimately included. These studies involved various types of surgery, including cardiac. One study found that patients treated by female surgeons compared with male surgeons had a lower 30-day mortality. The other study, however, found no differences in patient outcomes by surgeon's sex. There were no studies that investigated anaesthesiologist's sex/gender. There were also no studies investing physician's sex or gender exclusively in the cardiac operating room.

Conclusions The limited data surrounding the impact of physician's sex/gender on the outcomes of cardiac surgery inhibits drawing a robust conclusion at this time. Results highlight the need for primary research to determine how these factors may influence cardiac operative practice, in order to optimise provider's performance and improve outcomes in this high-risk patient group.

INTRODUCTION

Approximately two million cardiac surgical procedures are performed globally every year.¹ Complication rates after cardiac surgery vary from 2% to 60%, depending

Strengths and limitations of this study

- This is the first systematic review to assess the impact of physician's sex and gender on patient outcomes in cardiac surgery.
- The robust search strategy and screening process identified two indirectly relevant articles, which included cardiac surgery as one of many specialties assessed.
- A potential limitation of this study is that only articles published in English or French were included; however, we address two potentially relevant studies published in other languages in our discussion.
- Findings highlight an important knowledge gap related to physician's sex/gender in the cardiac operating room, and in particular, as it relates to anaesthesiologists' practice as the included studies, only studied surgeons.

on the outcome examined.^{2–6} Importantly, many of these complications are preventable, and are related to ineffective teamwork in the operating room (OR).^{7–16} Effective teamwork encompasses both observable behaviours and clinicians' perceptions of interpersonal processes.^{17–18} Though all team members play an important role, the relationship between the surgeon–anaesthesiologist dyad, who 'sometimes share, yield or compete for leadership', most critically influences overall OR team performance.¹⁹ Research has identified tension between anaesthesiologists and surgeons as potentially arising from misperceptions of each other and discrepant views on which their quality of collaboration and communication was built.^{19–24} Though power struggles in the OR have often been attributed to differences in professional training or values,¹⁵ research increasingly suggests that sex (ie, biological, anatomical and physiological characteristics) and gender (ie, identity,

behaviour, roles and relations) shape team interactions in healthcare, as well as the different practice patterns observed among female and male physicians.^{25–34}

Cohesive teamwork and effective communication are especially important in the cardiac OR given the high acuity of cases, frequent and sudden events of haemodynamic instability, critical moments of cardiopulmonary bypass initiation and separation, and the need for precise blood pressure control during key stages of operation. Moreover, the high-risk nature of cardiac surgery makes effective teamwork and communication even more critical in this operative setting. The predominance of male physicians in the cardiac OR compared with other surgical specialties³⁵ may carry implications for operative communication and teamwork related to gendered hierarchies. For example, studies on non-cardiac OR teams show that female staff anaesthesiologists are challenged more often by the respiratory therapist than their male colleagues when an incorrect clinical decision is made.^{32–34} This suggests that there are implicit gender hierarchies within the OR and a potential reduction in the professional hierarchy gradient associated with female leadership. Another study found that if the attending surgeon's gender differed from the primary gender composition of the overall surgical team, cooperation increased and conflict decreased.³³ Specifically, cooperation and communication were observed to decrease when more than half of the providers in an OR were male.³³ The highest percentage of conflict interactions was observed in the cardiothoracic OR, where over 95% of staff surgeons were male.³³ With increasing gender diversity in surgery, however, it is likely that team dynamics will also evolve.

Sex and gender may also be relevant to the performance of individual physicians in the cardiac OR. Recent findings also suggest that male anaesthesiologists spend a greater proportion of time and may thus be more experienced with the care of complex cardiac and/or vascular patients than their female counterparts.³⁶ This remains true despite the increasing number of female providers entering the specialty.

Although physician's sex and gender have been shown to influence processes of care and outcomes in non-cardiac medical and surgical care as well as in primary cardiac care,^{25–26–37–42} the role of these factors within the cardiac OR remains unclear. As such, it is necessary to quantify the effect of physician's sex and gender on clinical processes of care and adverse patient outcomes for the cardiac OR. To this end, we conducted a systematic review to analyse the role of anaesthesiologists' and surgeons' sex and gender in relation to processes of care and/or clinical outcomes within the context of cardiac operative care.

METHODS

This review was conducted and reported in accordance to the Preferred Reporting Items for Systematic Reviews and

Meta-Analyses (PRISMA).⁴³ The protocol was published in the University of Ottawa's research repository.⁴⁴

Eligibility criteria

Studies were included if they involved surgical patients of any age who underwent a cardiac surgical procedure requiring anaesthetic care, as long as there were specific investigations on the impact of medical provider's (eg, cardiac surgeon and cardiac anaesthesiologist) sex and/or gender on primary outcomes of process of care or patient outcome. Processes of care include but are not limited to hemostatic practices, antibiotic prophylaxis, selection of coronary artery bypass conduits and harvesting of these conduits (ie, pedicled vs skeletonised). Patient perioperative outcomes include postoperative 30-day mortality and complications (eg, chylothorax, sternal wound infection, acute kidney injury, venous thrombosis, stroke, improvement of left ventricular function, blood loss and length of hospital stay). Studies that did not specifically investigate the impact of provider's sex/gender on process of care within the cardiac OR or patient outcomes, or that focused on patient's sex/gender differences without considering provider's sex/gender, were excluded. Studies that explored the implications of surgeon sex and/or gender in a variety of surgical specialties met inclusion criteria as long as cardiac procedures were included. Both comparative interventional (eg, randomised control trials) and non-interventional (eg, cohort) studies of any design were eligible for inclusion if they were published in a peer-reviewed journal. Letters, editorials, opinion pieces, conference abstracts and reviews were excluded. Grey literature produced outside of conventional scientific publishing and distribution was not considered for this review.

Search strategy and information sources

The search strategy was developed in collaboration with an experienced information specialist (Alexandra Davis) (online supplemental appendix 1). The strategy was then reviewed by a second information specialist as per Peer Review of Electronic Search Strategies guidelines.⁴⁵ Searches were conducted in the electronic databases PsycINFO, Embase, Medline and Medline in Process (via OVID) from inception to 6 September 2018. Date and language restrictions were not applied; however, we planned to extract data from only those studies published in English or French. We also planned to search reference lists of included articles and to submit the final list of included studies to a group of experts (researchers, anaesthesiologists and surgeons involved in cardiac care) to verify relevance and accuracy.

Study selection

DistillerSR systematic review software (Evidence Partners, Ottawa, Canada) was used to facilitate the study screening and selection process. Screening forms were developed and piloted by members of the review team prior to undertaking full screening (AJ, FM, HS and KZ). Titles

and abstracts were screened for eligibility in duplicate by two pairs of independent reviewers (AJ, FM, HS and KZ). The full texts of titles and abstracts deemed potentially relevant by two reviewers were then reviewed. At each level of screening, disagreements were resolved through consensus or discussion with a third reviewer, if necessary.

Data items and abstraction

Data abstraction was conducted in duplicate by two pairs of independent reviewers using an electronic form in DistillerSR. The form included publication details (eg, first author, year and country of data collection), clinical context (eg, type of procedure, type of anaesthesia and urgent or elective procedure), population demographics (eg, sex/gender of patients/providers, patient comorbidities and patient age), study details (eg, research question/objective and methods used), outcomes assessed (ie, process of care or patient outcomes studied, definition and timing) and study results (ie, the reported impact of provider's/patient's sex/gender on process of care/patient outcomes). To ensure that the study was inclusive of all eligible papers, we wanted to avoid limiting the inclusion criteria by outcomes defined a priori. Meta-analysis was not conducted, as it may not be suitable in capturing the breadth of the clinical outcomes that arise in eligible studies.

Risk of bias

The NIH Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies was used to assess risk of bias.⁴⁶ This tool includes 14 dichotomous items (ie, yes or no), such as clarity of the research question, specification of the study population, sample size justification and measurement of confounding variables. Studies are assigned a score of '1' if the criterion is present, for a total possible score of 14 (high quality). Reviewers assessed risk of bias independently and in duplicate, using consensus or third reviewer consultation to resolve disagreements (MD and FM).

Patient and public involvement

No patients were involved.

RESULTS

Study selection

The search yielded 3296 publications. After removal of duplicates, 2095 underwent title and abstract screening, and 2076 were removed due to failure to meet our eligibility criteria of assessing the impact of healthcare provider's sex/gender on processes of care and patient outcomes in the setting of cardiac surgery. Nineteen studies proceeded to full-text screening by satisfying the inclusion criteria on abstract screening or the abstract did not provide information to confidently be excluded without full-text review. After full-text review, 17 were excluded based on our predetermined inclusion and exclusion criteria. The study PRISMA flow diagram is

shown in [figure 1](#). A list of studies excluded at level 2 (with reasons) is provided in (online supplemental appendix 2).

Study characteristics and synthesis

There were two eligible English studies indirectly assessing the impact of healthcare provider's sex or gender in cardiac surgery in this systematic review. These studies are described below and summarised in [table 1](#).

An observational study by Tsugawa *et al*⁴⁷ done in acute care hospitals across the USA evaluated the age and sex of surgeons on operative mortality of 892 187 patients over 65 years of age undergoing 1 of 20 major non-elective surgeries from 2011 to 2014, 4 of which were common cardiovascular procedures (ie, carotid endarterectomy, heart valve procedures, coronary artery bypass grafting and abdominal aortic aneurysm repair). Among 45 826 surgeons across the scope of surgical disciplines, 30-day mortality did not differ significantly between male (n=41 192) and female (n=4 634) surgeons (OR 0.97, 95% CI 0.93 to 1.01). No sub-group analysis was conducted for cardiothoracic procedures.

A retrospective matched cohort study by Wallis *et al*²⁹ explored the adverse postoperative outcomes (death, readmission or complications) among 104 603 patients seen by female and male surgeons in Ontario, Canada, from 2007 to 2015, across 25 elective and non-elective procedures, including coronary artery bypass grafting. Overall, patients treated by female surgeons had a small but statistically significantly lower 30-day mortality (adjusted OR 0.88, 95% CI 0.79 to 0.99, p=0.04) and comparable surgical outcomes (length of stay, complications and readmission), compared with those treated by male surgeons. Among patients of female (n=4023) and male (n=4039) cardiothoracic surgeons, there is weak evidence towards more favourable outcomes by female surgeons, with an OR of 0.91 (95% CI 0.82 to 1.01) for postoperative adverse events.

Risk of bias assessment

The included studies were evaluated using the NIH Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies. The overall quality rating for the internal validity of each study was relatively high ([table 2](#)). Both studies mitigated risk of bias by having a well-defined research question, pre-specified eligibility criteria, justified duration of follow-up, consideration for key confounding variables and insignificant loss to follow-up, among others. Two deductions in quality rating were due to the inability in examining different levels of exposure as related to the outcome and in assessing exposure more than once over time, as gender was determined to be binary and fixed in both studies. Tsugawa *et al* received an additional quality rating deduction for failure to provide sample size justification, power description, or variance and effect estimates. Detailed ratings for each study can be found in online supplemental appendix 3.

Figure 1 Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram.

DISCUSSION

Summary of main results

The novelty of this systematic review lies in its aim to assess the impact of both anaesthesiologists' and surgeons' sex and/or gender on perioperative cardiac processes of care and/or clinical outcomes. Out of 2093 references that were initially screened, we identified two English articles that briefly refer to cardiac surgery in the discussion of this topic in surgical specialties at large. These articles referred only to the sex of surgeons but not to that of anaesthesiologists.

Our inclusion criteria pre-specified publications in English and French; however, we identified two articles published in other languages (one in Japanese and one in Spanish) that may be relevant. We screened the English-language abstract of the article published in Japanese,⁴⁸ which discusses the implications of coronary artery bypass grafting in female patients. The English language translation of the full Spanish article was provided by a scientific colleague who is a native Spanish speaker. This article discusses patient sex differences in valvular surgery outcomes.⁴⁹ Neither of these foreign language articles made clear references to provider's sex or gender.

Explanation of the findings

Sex and gender are key determinants of healthcare practices and their outcomes, including in patients who

undergo non-cardiac surgery.^{50–53} Two recently published observational studies^{29 31} remotely investigated patient outcomes between female and male cardiac surgeons; however, primary statistical analyses were conducted to include data across all surgical specialties. Tsugawa *et al* included Medicare beneficiaries over 65 years of age undergoing a variety of non-elective procedures. In this study, only 10.1% of surgeons were female and it is unclear how many specialised in cardiac surgery.⁴⁷ Hence, sex and gender analysis may have been underpowered in the arena of cardiac surgery practices. Wallis *et al* provided greater generalisability by considering all adult patients undergoing 25 common elective and non-elective procedures, with complete tracking of mortality and postoperative complications. Interestingly, Wallis *et al* noted some degree of evidence (OR 0.91, 95% CI 0.82 to 1.01) for superior composite outcome of postoperative death, readmission or complications in patients under the care of female cardiothoracic surgeons compared with male cardiothoracic surgeons. They attributed this finding to female surgeons' tendency to adhere to guidelines, provide patient-centred care and attention to communication and teamwork.^{54 55} Alternatively, this observation could also be explained by effect modification, as female surgeons were more heavily involved elective surgeries, which were in themselves associated better postoperative

Table 1 Characteristics and results of included studies (n=2)

First author, year	Study design and objective(s)	Type of procedure(s)	N providers (% female or male) and profession	N patients (% female or male)	Outcome (definition and timing)	Statistical results
Tsugawa, ⁴⁷ 2018	Design: observational study. Objective: to investigate whether patients' mortality differs according to the age and sex of surgeons	Hip and femur fracture, colorectal resection, cholecystectomy and common duct procedures, laminectomy, excision of peritoneal adhesions, fracture or dislocation of lower extremity other than hip or femur, lung resection, hysterectomy, amputation of lower extremity, nephrectomy, appendectomy, small bowel resection, pancreatic resection, gastrectomy, splenectomy, oesophageal resection, carotid endarterectomy, heart valve procedures, coronary artery bypass grafting and abdominal aortic aneurysm repair	N=45 826 surgeons Female=4634 (10.1%) Male=41 192 (89.9%)	N=892 187 Female=551 628 (61.8%) Male=340 559 (38.2%)	Operative mortality rate of patients, defined as death during hospital admission or within 30 days of the operative procedure	No evidence that adjusted operative mortality differed between patients treated by female vs male surgeons (adjusted mortality 6.3% for female surgeons vs 6.5% for male surgeons; adjusted OR 0.97 (95% CI 0.93 to 1.01). Subgroup analysis for cardiac surgery was not performed

First author, year	Study design and objective(s)	Type of procedure(s)	N providers (% female or male) and profession	N patients (% female or male)	Outcome (definition and timing)	Statistical results
Wallis, ²⁹ 2017	Design: population based, retrospective, matched cohort study. Objective: to examine the effect of surgeon's sex on postoperative outcomes of patients undergoing common surgical procedures	Coronary artery bypass grafting, femoral-popliteal bypass, abdominal aortic aneurysm repair, appendectomy, cholecystectomy, gastric bypass, colon resection, liver resection, hysterectomy, anterior or posterior spinal decompression, anterior or posterior spinal arthrodesis, craniotomy for brain tumour, total knee replacement, total hip replacement, open repair of femoral neck or shaft fracture, total thyroidectomy, neck dissection, lung resection, radical cystectomy, radical prostatectomy, transurethral resection of prostate, carpal tunnel release and breast reduction	N=3314 surgeons Female=774 (23.4%) Male=2540 (76.6%)	Before matching: N=1 159 687 Female=695 747 (60.0%) Male=463 940 (40.0%) After matching: n=104 630 Female=52 315 (50%) Male=52 315 (50%)	Composite of death, complications or readmission (to any hospital in the province of Ontario) in 30 days after surgery	Fewer patients treated by female surgeons died, were readmitted to hospital or had complications within 30 days (5810 of 52 315, 11.1%, 95% CI 10.9% to 11.4%) than those treated by male surgeons (6046 of 52 315, 11.6%, 95% CI 11.3% to 11.8%; adjusted OR 0.96, 95% CI 0.92 to 0.99, p=0.02). Patients treated by female surgeons were less likely to die within 30 days (adjusted OR 0.88; 95% CI 0.79 to 0.99, p=0.04), but there was no significant difference in readmissions or complications. In the subgroup analysis for cardiothoracic surgery, there was OR of 0.91 (CI 95% 0.82 to 1.01) for composite outcomes among patients treated by female and male surgeons, when stratified by physician, patient and hospital factors

Table 2 Risk of bias for included studies: NIH Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies

First author, year	Quality rating (/14)
Tsugawa, ⁴⁷ 2018	11
Wallis, ²⁹ 2017	12

outcomes as compared with urgent or emergent procedures.²⁹ Overall, the study by Tsugawa and colleagues did not provide subgroup analysis for cardiac surgery, while both the Tsugawa and Wallis studies failed to specify the proportion of male and female surgeons within each specialty. These studies were also limited by shorter lengths of postoperative follow-up (ie, 30 days), as well as unmeasured confounders such as complexity of the operation and underlying disease severity.

Anaesthesiologist's sex was not considered in either studies. The fact that there are no published studies that explicitly explore the impact of physician's sex and gender for both surgeons and anaesthesiologists in the context of cardiac surgery was an unexpected finding. Given the high-stake nature of cardiac surgery and the crucial importance of teamwork in this context, our finding draws attention to potentially missed opportunities to optimise team and individual performance, as well as patient outcomes. Growing evidence in cardiac medical care and in non-cardiac surgery has shown that physicians' sex and gender significantly impact care. For example, OR teamwork is integral to preventing and treating many intraoperative and postoperative complications and can also be shaped by the sex composition of the team as well as gender roles and norms.^{11 56} In addition, there is considerable imbalance of physician's sex in cardiac surgery as compared with other surgical specialties, such that cardiac surgery has traditionally been viewed as a field dominated by male physicians.³⁵ Therefore, an in-depth understanding of how physician's sex and gender influence team dynamics, in addition to individual performance, may inform future team-based interventions and ultimately mitigate preventable adverse events in cardiac surgery.^{57–60} Research in this domain might also inform an integrated clinical practice approach that moves beyond medical knowledge and experience, to individual and social factors. For example, educational interventions could be tailored based on provider's sex or cardiac OR scheduling apps could be designed to optimise OR team sex composition. Such an approach will shift the paradigm in patient safety research towards the personalisation of provider's characteristics, to provide all-around personalised medical care.

Future directions

Future research should consider physician's sex and gender when examining physician-related factors influencing surgical cardiac care. At minimum, studies should report the sex and/or gender characteristics of both the

healthcare providers and patients involved so that future meta-analyses may be possible.⁶¹ In addition, sex and gender are not the only physician characteristics relevant to performance and their salience may depend on other factors such as age, level of experience, region of training or cultural background.^{62–65} Thus, studies that integrate sex and gender variables may also consider how they intersect with additional categories of social identity. Attention to anaesthesiologist's sex/gender, in particular, would be warranted given the lack of literature in this area in addition to the potential interaction between anaesthesiologist and surgeon sex/gender.

Limitations of the study

While this review has identified a critical knowledge gap in cardiac surgical care, there are some limitations of this review that are to be noted. First, we included only studies published in English or French. Two other non-English/French studies were identified and were determined not to be relevant. Second, it is possible that studies examined physician's sex and/or gender as control variables but may have been excluded during title and abstract screening based on the failure of the study to specify this as a primary aim. Given our findings, combined with other systematic reviews showing the paucity of sex/gender analyses in medicine,⁶⁶ we believe it is unlikely that any relevant studies were missed by our search strategy or screening process.

Neither of the two studies included in this review specifically explored the impact of surgeon's and anaesthesiologist's sex or gender in the context of cardiac surgery in detail, nor did they include the processes of care as an outcome. Furthermore, the magnitude of reduction in adverse events and the methodology of propensity score matching used was at times unclear within the two observational studies presented in this review.^{29 31}

CONCLUSIONS

This systematic review found no English or French language publication directly assessing the role of physician's sex and/or gender in cardiac operative care. Two observational studies investigated the impact of surgeon's sex on patient outcomes across the full scope of surgical specialties. These findings highlight the need for primary research to determine how these factors may influence cardiac surgical practice, in order to optimise provider's performance and improve outcomes in this high-risk patient group.
