ABSTRACT

Objective To describe patterns and predictors of mortality in a semi-urban population in Sri Lanka.

Design A prospective population-based cohort study.

Setting Ragama Medical Officer of Health area in the Gampaha district, Sri Lanka.

Participants Adults between 35 and 64 years of age were recruited using an age stratified random sampling technique in 2007.

Measures At baseline, we recorded socio-demographic, lifestyle, anthropometric, biochemical and clinical data of the participants. Over 10 years, we obtained the cause and date of death from the death registration documents of deceased participants. We determined the survival probability of the cohort over 10 years and estimated Hazard ratios (HRs) for all-cause mortality (ACM), cardiovascular mortality (CVM) and cancer-related mortality (CRM) using Cox's proportional hazards model. We also estimated the survival probabilities for men and women in each 10-year age group and standardised mortality ratio relative to the source population.

Results There were 169 deaths over 10 years with standardised mortality rates of 5.3 and 2.4 per 1000 years of follow-up for men and women, respectively. Independent predictors of: ACM were older age, lower income, smoking and diabetes mellitus while gender, education, occupation, harmful alcohol use, waist circumference and hypertension were not; CVM were older age, lower income, smoking, diabetes and hypertension while gender and harmful alcohol use were not; CRM was older age while gender, smoking and diabetes were not. Those engaged in clerical and technical occupations or unemployed had a lower risk of CRM as compared with those engaged in elementary occupations.

Conclusions Older age, lower income, smoking, diabetes and hypertension strongly predict mortality in this cohort. Addressing the identified modifiable predictors through behavioural modification will improve longevity in similar populations.

INTRODUCTION

Mortality is one of the strongest indicators of the health status in a population and the

Strengths and limitations of this study

- This is a population-based prospective cohort study which provides high quality epidemiological evidence on temporal associations.
- We used national vital registration data with a high coverage and completeness (99.9%), but they may have inaccuracies in documenting the cause of death.
- Loss to follow-up of the original cohort (8.7%) is a limitation of this study.
- Relationships observed may be distorted by confounding, but multivariable analysis that have been carried out is likely to have minimised this.

easiest to measure due to it being an unambiguous endpoint.¹ Due to rapid socio-economic development and improved living conditions, significant reductions in adult mortality have been observed in all regions of the world in the last three decades. In both high-income and middle-income countries the most common cause of death is cardiovascular disease. South Asia, with a population of 1.9 billion, records over 12 million deaths annually² and the majority of these deaths are due to cardiovascular causes which are linked to intermediate metabolic conditions such as, diabetes mellitus and hypertension.³ It has been documented that people of South Asian origin develop diabetes mellitus at a younger age and at lower levels of metabolic risk when compared with Caucasians.⁴ South Asians who make up a considerable proportion of the migrant population in high-income countries have also shown a higher risk of diabetes at lower metabolic risk levels.^{5 6} Mortality due to cancer is estimated to be about 1.3 million deaths in South-East Asia region⁷

and accounts for about 10% of mortality in the region.⁸ All cause, cardiovascular and cancer mortality in Asia have shown strong links to socio-economic disadvantage.⁹ However, only a few studies have been conducted to describe the patterns and predictors of mortality in South Asian populations and even fewer are based on population-based cohorts.¹⁰

Well organised and functioning vital registration systems provide high quality and timely mortality data that are of great value for epidemiological purposes. At present, the rate of death registration in Sri Lanka exceeds 99% and on registration, a death certificate is issued. The death certificate includes the identification data of the deceased, the time, date, place and the medical cause of death and the designation and credentials of the officer certifying the death; it is required for the disposal of the deceased.¹¹ Although data from the vital registration system and hospital statistics provide evidence on the importance of cardiovascular disease as the leading cause of death across South Asia,^{12 13} there is limited epidemiological information on the patterns and predictors of mortality from population-based studies conducted in this region. This dearth of information hampers creating the awareness it deserves for better decision-making and resource allocation for appropriate public health and preventive measures for control of behavioural and metabolic risk factors of cardiovascular disease. Results from studies conducted outside South Asia have a limited impact on attracting the attention of local decision-makers and health administrators.

To address this dearth of information and the resultant gaps in practice, we conducted an analysis to describe the patterns of all-cause mortality (ACM), cardiovascular mortality (CVM) and cancer-related mortality (CRM) and their predictors in a population-based cohort in Sri Lanka, using baseline data of the cohort and mortality data reported by the vital registration system.

METHODS

Study design

We prospectively followed-up participants of a population based cohort study over a period of 10 years to correlate their baseline characteristics and mortality outcomes.

Study setting and population

Our cohort lives in the Ragama Medical Officer of Health (MOH) area in the Gampaha district of Sri Lanka. Gampaha district is the second most populous district of Sri Lanka with a population of approximately 2.3 million.¹⁴ Sri Lankans enjoy universal free education and free healthcare facilities at the point of delivery. Universal franchise was introduced in 1931 and all citizens above 18 years of age are included in the electoral register since 1959.¹⁵ Gampaha district with mostly rural and semi-urban characteristics, records the country's highest overall adult literacy rate of 98.5% and an overall life expectancy at birth of 73.2 years for men and 79.9

years for women.¹⁴ The district is divided into 16 MOH areas to provide population based preventive healthcare services.¹⁶ The Ragama MOH area, which has semi-urban characteristics and a population of 81 687 living in an area of 21 km², is the smallest of these and is the field practice area of the Faculty of Medicine, University of Kelaniya.¹⁷

At the commencement of the study in 2007, 3012 adults between 35 and 64 years of age living in the Ragama MOH area were recruited using age stratified random sampling from the electoral register (sampling frame) conforming to the ratio of 1:2:2 from each of the three 10-year age groups (35 to 44, 45 to 54 and 55 to 64 years, respectively).¹⁸ Participant recruitment was done between July 2007 and March 2008. At the baseline assessment 2985 of the recruited participants had complete data and were followed-up as the Ragama Health Study (RHS) cohort. We included all the participants of the RHS cohort in this analysis.

Data and data sources

After providing informed written consent at recruitment, the study participants underwent baseline screening that included anthropometric, clinical and biochemical assessments and their socio-demographic, lifestyle, medical and health-related information were obtained through an interviewer-administered questionnaire developed in the local languages. Medical history provided by the participants was verified with medical records by the medically qualified research staff. The assessment covered a wide range of risk factors attributed to cardiovascular diseases including biochemical tests for assay of blood glucose and lipids, serum insulin, glycated haemoglobin and alanine transaminase levels. In 2010 and 2014, two follow-up assessments of the cohort were conducted using similar methods. In 2014, 2148 (72%) of the 2985 original participants attended follow-up. The rest of the participants were followed-up in the community by research staff and their vital status was determined. If any participant had died, a copy of his/her death certificate was obtained and details were recorded. From July 2017 to November 2018, we conducted a population based follow-up of the RHS cohort at household level by contacting all households by telephone or by post, followed by home visits if a death was reported. The follow-up visits were conducted by trained research assistants with a medical/health sciences background, who met family members of the deceased participants to collect information on their cause of death. They obtained a copy of the death certificate to correctly ascertain the date and the cause of death. If the death certificate was not available with the family, more preliminary hospital or field death declaration documents were perused to ascertain the date and the cause of death. The vital status of 2724 (91.3%) participants was obtained. The database was updated with the outcome data obtained during the follow-up assessment after a cleaning and verification process. At each stage of this prospective cohort study, participants who did not participate were (1) those who did not wish to be followed-up

Figure 1 The flow of participants through the follow-up period.

in the study, (2) those who migrated out of the area or (3) those who migrated overseas. The flow of participants through the follow-up period and how their outcome was ascertained is given in figure 1.

Data analysis

We constructed Kaplan-Meier survival curves to determine the survival probability of the cohort after accounting for all-cause mortality, and mortality due to cardiovascular and cancer-related causes, at 10 years from recruitment. The participants who were not traceable in 2017 were censored at their last date of contact. We compared deceased persons and persons alive by important baseline characteristics. We considered socio-demographic variables defined as follows: age defined by number of completed years at recruitment, sex as the reported biological sex, low educational level as having an educational level below General Certificate of Education (G.C.E.) Ordinary Level completion, low income as belonging to the lowest income quartile of the study population and occupation based on the classification of International Labour Office.¹⁹ Smoking status was defined by reported use on an average day (current smoker/past smoker/never smoker). Harmful alcohol use was defined by Asian cut-offs for harmful alcohol consumption (14IU/week for men and 7IU/week for women) estimated using reported weekly consumption. Obesity was defined as a body mass index ≥ 25 kg/m². A waist circumference ≥ 90 cm for men and ≥ 80 cm for women was defined as a high waist circumference. Presence of diabetes was defined as a verifiable past history of diabetes or having a fasting blood glucose level ≥ 126 mg/dL at baseline. Hypertension was defined as a verifiable past history of high blood pressure or persistent systolic blood pressure ≥ 140 mm Hg and/or diastolic blood pressure ≥ 90 mm Hg at baseline. Dyslipidaemia was defined as a verifiable past history of dyslipidaemia or having a total cholesterol level ≥ 240 mg/dL or a low-density lipoprotein cholesterol level ≥ 160 mg/dL or a serum triglyceride level

≥ 150 mg/dL or a high-density lipoprotein (HDL) cholesterol level below sex specific cut-offs for HDL (≤ 40 mg/dL for men and ≤ 50 mg/dL for women) at baseline.

Survival analysis was done using right censored data. Follow-up time was defined as the time between 2007 to death, or the date at which the patient was last confirmed to be alive (censoring time). Comparison of survival rates due to ACM, CVM and CRM by age-sex strata within ACM, CVM and CRM were conducted using Kaplan-Meier survival function curves. Cox's proportional hazards (CPH) models were used to identify independent risk factors of mortality due to ACM, CVM and CRM. Initially the probable risk factors were screened with simple CPH models and the risk factors with a $p < 0.2$ were considered for constructing multivariable CPH models for ACM, CVM and CRM. Effects of risk factors on mortality are presented as HRs and their 95% CIs.

We standardised the observed mortality rates using the method of indirect standardisation for the district and the country and constructed life tables for the cohort.

Missing data

Among variables collected at baseline, the percentage of missing data was small. We censored our outcome variables, ACM, CVM and CRM at the last date of contact with the research staff, if they could not be traced in the community or if they were already lost to follow-up. We did not perform sensitivity analyses. We have indicated the numbers available for each variable in table 1. We have also compared the baseline socio-demographic characteristics of the participants who were and were not traced in online supplemental table 1.

Potential sources of bias

We have attempted to address potential sources of bias using a set of strategies in the design of this study. The participants were sampled using stratified random sampling allowing for representative sampling from the reference population within the specific age strata to address selection bias. Information bias was minimised through the use of standard interviewer-administered questionnaires for data collection and regular in-service training of data collectors who were from a medical or health sciences background. Certain data collected from participants have been verified with documented information, for example, medical history. Outcome data have been obtained from official documents minimising information bias. We have also attempted to minimise confounding through use of multivariable models to determine predictors of mortality.

Patient and public involvement

The study was designed in 2007. At the design stage, participants were not consulted on development of research questions or outcome measures. However, non-communicable diseases, especially cardiovascular disease, diabetes and hypertension were recognised as important public health problems by the public and the study

Table 1 Baseline characteristics of the RHS cohort

Characteristic*	Total	Alive	Deceased from all causes	Deceased from cardio-vascular causes	Deceased from cancer-related causes
Mean age (SD) years (n=2985)	52.4 (7.8)	52.2 (7.8)	56.9 (6.0)	57.4 (5.4)	57.5 (5.2)

BMI, body mass index; G.C.E., General Certificate of Education; RHS, Ragama Health Study.

addressed a well-recognised gap in knowledge. The public was involved in participant recruitment and follow-up in this study. Community volunteers provided support to the research team to access selected participants throughout the recruitment phase. In the follow-up phase, the death registration documents available with the family members of the participants was the main source of outcome information. They were retrieved with the co-operation of the family members. The results of this analysis will be disseminated to the study participants and their families through the RHS clinic and information leaflets delivered to their homes via post.

RESULTS

At recruitment, the mean age of our cohort was 52.4 (SD=7.8) years with 1349/2985 (45.2%) men. Respectively

17.2, 38.2% and 44.6% of the sample were distributed in the three 10-year age groups 35 to 45 years, 45 to 54 years and 55 to 64 years. Overall, 45.5% had received an education below G.C.E. Ordinary Level and 14.3% were in the lowest income quartile. Selected baseline socio-demographic, lifestyle, anthropometric and clinical characteristics of the participants are presented in relation to their vital status in [table 1](#). During the period 2007 to 2018, 169 (107 men) participants had died giving an overall crude mortality rate of 7.9% for men and 3.8% for women. Standardised mortality rates were 5.3 and 2.4 per 1000 years of follow-up for men and women, respectively. Survival probability of the cohort overall and in relation to cardiovascular and cancer-related causes are shown in [figure 2](#). Overall survival of the cohort at 10 years was 95.1% (94.3 to 95.9). Survival probabilities of men and

Figure 2 Survival probability of the cohort overall and in relation to cardiovascular and cancer-related causes. ACM, all-cause mortality; CRM, cancer-related mortality; CVM, cardiovascular mortality.

women in baseline age groups 35 to 44, 45 to 54 and 55 to 64 years for ACM, CVM and CRM are presented in figure 3.

HRs of selected individual variables for ACM, CVM and CRM are presented in table 2. Older adults (45 to 54 years HR=4.35 (95% CI: 1.73 to 10.92)), (55 to 64 years, HR=9.21 (95% CI: 3.76 to 22.5)), men (HR=2.15 (95% CI: 1.58 to 2.95)), those with a lower educational level (HR=1.55 (95% CI: 1.15 to 2.11)) and a lower income (HR=1.95 (95% CI: 1.37 to 2.78)), smokers (ex-smokers HR=3.20 (95% CI: 2.23 to 4.60)) and (current smokers HR=1.97 (95% CI: 1.34 to 2.88)), harmful alcohol users (HR=1.80 (95% CI: 1.29 to 2.51)), those with diabetes (HR=3.03 (95% CI: 2.24 to 4.11)) and hypertension (HR=1.69 (95% CI: 1.25 to 2.30)) had a significantly higher risk of ACM. The unemployed (HR=0.54 (95% CI: 0.32 to 0.88)), professionals or administrators (HR=0.44 (95% CI: 0.21 to 0.91)) and those with a higher waist circumference (HR=0.72 (95% CI: 0.53 to 0.98)) had a significantly lower risk of ACM. Older adults (45 to 54 years HR=8.61 (95% CI: 1.15 to 64.28)), (55 to 64 years HR=20.80 (95% CI: 2.88 to 150.45)), males (HR=2.12 (95% CI: 1.32 to 3.41)), those with a lower income (HR=1.86 (95% CI: 1.08 to 3.22)), ex-smokers (HR=3.20 (95% CI: 1.86 to 5.50)), harmful alcohol users (HR=1.81 (95% CI: 1.09 to 3.01)), those with diabetes (HR=3.95 (95% CI: 2.48 to 6.27)) and hypertension (HR=2.61 (95%

Figure 3 Survival probabilities of men and women in baseline age groups. ACM, all-cause mortality; CRM, cancer-related mortality; CVM, cardiovascular mortality.

CI: 1.60 to 4.26)) had a significantly higher risk of CVM. Older adults (55 to 64 years HR=3.14 (95% CI: 1.45 to 6.83)), ex-smokers (HR=2.64 (95% CI: 1.09 to 6.42)) and those with diabetes (HR=2.41 (95% CI: 1.18 to 4.92)) had a significantly higher risk of CRM. The unemployed (HR=0.27 (95% CI: 0.10 to 0.68)) and clerical and technical workers (HR=0.29 (95% CI: 0.09 to 0.91)) had a significantly lower risk of ACM.

Results of multiple variable analysis performed to determine independent predictors of mortality are presented in table 3. The risk of ACM increased in those between 45 and 54 years of age by 3.42 (95% CI: 1.35 to 8.63) and in those between 55 and 64 years of age by 5.99 (95% CI: 2.42 to 14.83) as compared with those between 35 and 44 years of age; in those in the lowest income quartile by 1.91 (95% CI: 1.33 to 2.75) as compared with those with a higher income; in a past smoker by 2.95 (95% CI: 2.02 to 4.32) and a current smoker by 2.60 (95% CI: 1.75 to 3.87) as compared with a non-smoker; and in those with diabetes at baseline by 2.86 (95% CI: 2.08 to 3.93) as compared with non-diabetics. The risk of CVM increased in those between 55 and 64 years of age by 10.10 (95% CI: 1.37 to 74.61) as compared with those between 35 and 44 years of age; in those in the lowest income quartile by 1.83 (95% CI: 1.04 to 3.21) as compared with those with a higher income; in a past smoker by 2.77 (95% CI: 1.55 to 4.97) and a current smoker by 2.31 (95% CI: 1.21 to 4.41) as compared with a non-smoker; in those with diabetes

Dyslipidaemia	0.97 (0.71 to 1.33)	1.19 (0.73 to 1.96)	0.73 (0.35 to 1.50)

Bold statistics indicate significant variables - that is, 1 is not included in the 95% CI.

*The age groups 35 to 44 years, 45 to 54 years and 55 to 64 years have been sampled in 1:2:2 ratio

BMI, body mass index; G.C.E., General Certificate of Education.

at baseline by 3.30 (95% CI: 2.07 to 5.58) and those with hypertension at baseline by 1.90 (95% CI: 1.12 to 3.25) as compared with those without. The risk of CRM increased in those between 55 and 64 years of age by 3.19 (95% CI: 1.44 to 7.05) as compared with those between 35 and 54 years of age. Those in clerical and technical occupations (HR=0.31 (95% CI: 0.10 to 0.96)) and those who are unemployed (HR=0.21 (95% CI: 0.08 to 0.55)) had

a lower risk of CRM as compared with those in elementary occupations. Indirect standardisation of observed mortality rates for men and women showed that mortality in this cohort was about 50% lower compared with the district and national populations (table 4).

Comparison of basic socio-demographic characteristics of the RHS cohort who were traced and not traced in 2017/2018 for outcome ascertainment is presented in

Table 3 Risk factors of all-cause, cardiovascular and cancer mortality from multiple variable analysis

Risk factor (at baseline)	HR	95% CI	P value
All-cause mortality			
Age group : 45–54 vs 35–44 years	3.42	1.35 to 8.63	0.009
55–64 vs 35–44 years	5.99	2.42 to 14.83	<0.001
Lowest income quartile	1.91	1.33 to 2.75	<0.001
Smoking : Ex-smokers vs non-smoker	2.95	2.02 to 4.32	<0.001
Smokers vs non-smoker	2.60	1.75 to 3.87	<0.001
Diabetes	2.86	2.08 to 3.93	<0.001
Cardiovascular mortality			
Age group : 45–54 vs 35–44 years	5.54	0.73 to 41.81	0.097
55–64 vs 35–44 years	10.10	1.37 to 74.61	0.023
Lowest income quartile	1.83	1.04 to 3.21	0.035
Smoking : Ex-smokers vs non-smoker	2.77	1.55 to 4.97	<0.001
Smokers vs non-smoker	2.31	1.21 to 4.41	0.011
Diabetes	3.30	2.07 to 5.58	<0.001
Hypertension	1.90	1.12 to 3.25	0.018
Cancer-related mortality			
Age group : 55–64 vs 35–54 years*	3.19	1.44 to 7.05	0.004
Occupation: Professional/administration vs elementary	0.22	0.04 to 1.07	0.061
Clerical/technical vs elementary	0.31	0.10 to 0.96	0.042
Unemployed vs elementary	0.21	0.08 to 0.55	0.001

*There were no cancer-related deaths in 35 to 44 age group. Therefore, age groups 35 to 44 and 45 to 54 were merged together.

online supplemental table 1. Life tables constructed for the RHS cohort are presented in online supplemental table 2.

DISCUSSION

We have demonstrated the patterns and predictors of ACM, CVM and CRM in a cohort of semi-urban adults living in Sri Lanka, using baseline data of a prospective population-based cohort study and mortality data from the national vital registration system. Our cohort comprised middle-aged adults with a mean age of 52.4 (SD=7.8) years at baseline and 45% men. The overall survival probability of the cohort was 95.1% at 10 years after recruitment. ACM was associated with older age groups, low income, both current and previous smoking and diabetes at baseline. CVM was associated with older age groups, low income, both current and previous smoking, diabetes and hypertension at baseline. CRM was associated with older age and those engaged in clerical and technical occupations and those who are unemployed had a lower risk of CRM as compared with those in elementary occupations.

Older age is the main risk factor for mortality globally.²⁰ We found that low income was associated with both ACM and CVM, while CRM was associated with elementary occupations. The association between poverty and mortality is well documented.^{21 22} Diabetes was also associated with both ACM and CVM. Diabetes has been

identified as the third leading contributor for deaths in Sri Lanka, behind ischaemic heart disease and stroke.²³ Similar to documented findings,^{24–26} both current and past smoking was associated with ACM. Hypertension at baseline was associated with CVM, similar to findings from a number of cohorts across settings in both high-income and middle-income regions.^{12 20} Our findings highlight the importance of well-known non-modifiable predictors of mortality, such as, older age, while at the same time demonstrating that well-recognised modifiable risk factors of mortality like low income, elementary occupations, current and past smoking, diabetes and hypertension are associated with ACM and CVM in this population.

Standardisation of the mortality data of our cohort for the district showed that our population is healthier than the general population. The RHS cohort population lives in the catchment area of the Colombo North Teaching Hospital which is the second largest tertiary care hospital in the country in terms of bed strength and healthcare facilities. The area also has two large private hospitals and many general practice clinics. In addition, the population has exclusive access to long-term and continuing health facilities in the RHS clinic at the Faculty of Medicine, University of Kelaniya, since the formation of the cohort to-date. This service has offered routine follow-up care, health advice and a continuous supply of medication to all participants who have metabolic conditions

Table 4 Indirect standardisation of mortality for men and women

Age group (years)	Total number of person years within the age group	Total number of observed deaths	Expected number of deaths if applied to Gampaha district	Expected number of deaths if applied to Sri Lanka
Men				
35–39	237	0	0	1
40–44	839	0	2	3
45–49	1555	3	8	8
50–54	2168	3	17	17
55–59	2657	20	31	31
60–64	2790	22	47	49
65–69	2090	40	55	58
70–74	763	18	31	33

Total	16 362	62	113	123

like diabetes and hypertension with referral links to specialised care based on requirement. Volunteer bias in participation in screening and research programmes and intensified health services available to the participants of this cohort could be responsible for their apparent better health status.

Our cohort of 2985 participants is a relatively small cohort from South Asia. However, our comprehensive baseline data and stringent follow-up mechanisms, together with a reliable vital registration system strengthen the relevance of our findings and their applicability for the country and the region. Population based cohort studies provide the most robust methodology for determining the temporal association between a risk factor and its outcome in a population.²⁷ We have taken steps to address the effect of confounding on these relationships through multiple variable analysis. Sri Lanka's vital registration system has been in operation for over 100 years.²⁸ Transformations in knowledge and technology over the last two to three decades have led to improvement in documentation of vital events and the use of modern information technology for collecting, storage and retrieval of vital statistics.¹¹ It is a legal requirement for all births and deaths to be registered in the vital registration system.²⁸ Furthermore, availability of the death certificate issued by the Registrar General's Department is mandatory for death

benefits and property settlements, and are retained by the next-of-kin of the deceased and the local public administration system.²⁹ In the absence of complete and up-to-date health information systems covering risk levels and outcome information, the methods we have employed, which are straightforward and simple enough to be easily replicated by other researchers with similar data sources, can be used to determine the patterns and predictors of mortality in any low-income and middle-income setting with a reasonable vital registration system.

The predictors of mortality reported in this study are well known. However, this is the first time this has been reported for this setting. The added benefits of reporting these results are (1) it can increase the emphasis on preventing identified modifiable risks, (2) allocation of limited health resources can be planned to target these conditions and (3) increase the attention of policymakers to prevent premature mortality.

Limitations

The relatively small size of the cohort and the modest number of mortality outcomes reported over the first 10 years of follow-up is our main limitation. Due to the small number of outcomes we were compelled to categorise mortality into three main groups as ACM, CVM and CRM. We expect to follow-up this cohort long-term and examine

the mortality trends over the next 10 years to address this limitation. Despite improvements in recording cause of death in mortality statistics, deficiencies can exist in the death registration process that can reduce the accuracy of documenting the cause of death. Validating the documented cause of death in official documents was beyond the scope of this study and we acknowledge this as a potential limitation.

Sri Lanka being a small country with access to free education and healthcare has minimal country-wide variation. Given the diversity of the study area in the Gampaha district, we believe that the risk factor prevalences and associations reported in different subpopulations in this study will be the same for generalising the findings of the study both in Sri Lanka and the South Asian region.

Recommendations

Low income is known to be associated with increased ACM across high-income, middle-income and low-income countries and even where health systems are tax funded and provided free at the point of delivery.^{22 30} Many underlying mechanisms that link poverty with poorer health outcomes like socio-economic barriers for access to healthy behaviours, and the resulting choice of unhealthy alternatives, exist at population level.^{31 32} Universal measures to improve living standards by addressing poverty can create manifold benefits including the promotion of healthy behaviours that can reduce the incidence and improve the control of intermediate metabolic risk factors of common mortality outcomes, and thus improve longevity. Along with this, preventive health services should increase their emphasis on behavioural modification for healthy lifestyles at population level to address tobacco control, and prevention and control of diabetes and hypertension.

Contributors AK, NK, ARW and HJdS conceptualised and designed the study. STDS, MAN, ASD, APDS, SC and UR managed the study implementation and data collection. AP, DSE and UBT managed the database and conducted the data analysis. AK and HJdS drafted the manuscript. All authors contributed to improving and approval of the final version of the manuscript.

Funding This work was supported by grants from the National Center for Global Health and Medicine (17K1); KAKENHI (Grant-in-Aid for Scientific Research (B) #20406019) from the Ministry of Education, Culture, Sports, Science and Technology of Japan; Japan International Co-operation Agency through the project on Health Promotion and Preventive Care Measures of Chronic Non-communicable Diseases (NPP) implemented by the Ministry of Health, Sri Lanka (project #0701475); Strengthening Research Grant from the Ministry of Higher Education, Sri Lanka.

Competing interests None declared.

Patient and public involvement Patients and/or the public were involved in the design, or conduct, or reporting, or dissemination plans of this research. Refer to the Methods section for further details.

Patient consent for publication Not required.

Ethics approval Ethical clearance was obtained from the Ethics Review Committee, Faculty of Medicine, University of Kelaniya, for both baseline and follow-up assessments of the Ragama Health Study and principles of ethical research were upheld in all encounters with the participants.

Provenance and peer review Not commissioned; externally peer reviewed.

Data availability statement Data are available upon reasonable request. De-identified participant data will be available upon reasonable request as decided by the data management committee of the RHS. Please contact the corresponding author (Anuradhani Kasturiratne, ORCID ID 0000-0001-5260-2394).
