**Effect of music on clinical outcome after hip fracture operations (MCHOPIN): study protocol of a multicentre randomised controlled trial**

Victor X Fu, Johannes Jeekel, Esther M M Van Lieshout, Detlef Van der Velde, Leonie J P Siegers, Robert Haverlag, Johan Haumann, Marten J Poley, Michael H J Verhofstad, on behalf of the MCHOPIN collaborators

**ABSTRACT**

**Background** Patients undergoing proximal femur fracture surgery are at high risk of postoperative complications, with postoperative delirium occurring in 25%–40% of patients. Delirium has profound effects on patient outcome and recovery, the patient’s family, caregivers and medical costs. Perioperative music has a beneficial effect on eliciting modifiable risk factors of delirium. Therefore, the aim of this trial was to evaluate the effect of perioperative recorded music on postoperative delirium in patients with proximal femur fracture undergoing surgery.

**Methods and analysis** The Music on Clinical Outcome after Hip Fracture Operations study is an investigator-initiated, multicentre, randomised controlled, open-label, clinical trial. Five hundred and eight patients with proximal femur fracture meeting eligibility criteria will be randomised to the music intervention or control group with concealed allocation in a 1:1 ratio, stratified by hospital site. The perioperative music intervention consists of preselected lists totalling 30 hours of music, allowing participants to choose their preferred music from these lists (classical, jazz and blues, pop and Dutch). The primary outcome measure is postoperative delirium rate. Secondary outcome measures include pain, anxiety, medication requirement, postoperative complications, hospital length of stay and 30-day mortality. A 90-day follow-up will be performed in order to assess nursing home length of stay, readmission rate and functional ability to perform daily living activities. Furthermore, the cost and cost-effectiveness of the music intervention will be assessed. Data will be analysed according to an intention-to-treat principle.

**Ethics and dissemination** The study protocol has been approved by the Medical Research Ethics Committee Erasmus MC on 8 October 2018 (MEC:2018–110, NL64721.078.18). The trial will be carried out following the Declaration of Helsinki principles, Good Clinical Practice guidelines and Dutch Medical Research Involving Human Subjects Act. Research data will be reported following Consolidated Standards of Reporting Trials guidelines and study results will be published in a peer-reviewed journal.

**Trial registration number** NTR7036.

**INTRODUCTION**

Proximal femur fractures are common in the elderly and are primarily treated surgically. These frail patients are at a high risk of the occurrence of postoperative complications, as they often have significant comorbidity with polypharmacy use. A prevalent in-hospital complication of the elderly is delirium, an acute, fluctuating, cognitive and consciousness disorder. Postoperative delirium rates in elderly Dutch patients who underwent surgery for proximal femur fracture have been observed to vary between 25% and 40%. It has been associated with an increased rate of additional postoperative complications, a prolonged length of hospital stay and higher medical costs. Moreover, it has a thorough impact on the...
patient’s family, increasing the risk of poor, long-term functional recovery and mortality rate.

As the consequences of experiencing an episode of delirium are profound, delirium is nowadays regarded as a state of acute brain dysfunction. Therefore, there is an increasing interest in delirium prevention and reduction. The exact pathophysiological mechanism of delirium is multifactorial and complex. Primary prevention with non-pharmacological interventions is generally regarded as the most accepted and effective treatment strategy, especially since conflicting reports on the effectiveness of prophylactic drug use to prevent delirium have been reported. Multiple modifiable precipitating risk factors have been identified. These include increased postoperative pain levels, higher opioid, sedative and benzodiazepine medication dosages, as well as a more vigorous physiological stress response to surgery and elevated stress hormone cortisol level. Current patient care aims to reduce these risk factors in order to prevent delirium.

Perioperative recorded music as a non-pharmacological intervention can reduce postoperative pain, intraoperative sedative and postoperative opioid medication requirement, and attenuate the physiological stress response to surgery. Comparisons have been drawn with the most well-known non-pharmacological interventions for surgery, collectively known as the Enhanced Recovery After Surgery protocols, which have the same objectives. Moreover, the music intervention seems to be well liked by patients, with high patient satisfaction levels and willingness to listen to perioperative music again if they were to undergo surgery in the future. The effects of perioperative music on postoperative complications, patient outcome and recovery have only sparingly been investigated, with most studies focusing on postoperative pain levels, anxiety or medication requirement in the first few days after surgery. To date, only four small studies in elective knee and hip replacement surgery with sample sizes of 60 patients or less examined the effect of music on confusion and cognitive functioning in adult surgical patients. Only two used a delirium screening tool, but positive results were reported in all studies.

This multicentre randomised controlled trial will investigate whether perioperative music can reduce the occurrence of postoperative delirium in elderly patients with proximal femur fracture undergoing surgery. Secondary objectives were to assess the effects of perioperative music on pain, anxiety, medication use, postoperative complications, neurohormonal stress response, hospital length of stay, nursing home length of stay, 30-day mortality, 90-day readmission, 90-day functional ability to perform daily living activities, costs and cost-effectiveness.

METHODS AND ANALYSIS
Trial design and setting
The Music on Clinical Outcome after Hip Fracture Operations (MCHOPIN) study is an investigator-initiated, multicentre, randomised, controlled, open-label clinical trial. Patients with proximal femur fracture meeting eligibility criteria will be randomised to the music intervention or control group using a secure web-based, computerised randomisation system with concealed allocation in a 1:1 ratio, stratified by hospital site. Only study staff members and their delegates will have login credentials. The randomisation code for allocation will be kept concealed from the study staff recruiting patients. The music group will receive recorded music as an intervention before, during and after surgery, while the control group will not, but will wear headphones without music during surgery instead. The study will take place in three non-academic hospitals and one academic hospital. Patients will be followed up until 90 days after the proximal femur fracture surgical procedure.

Eligibility, recruitment and consent
Potential eligible patients will be informed about the MCHOPIN study while in the emergency department or on admission to the surgical ward. Information will be provided verbally as well as on paper through a patient information folder with an informed consent form (online supplemental file 1). Patients meeting eligibility criteria and willing to participate will be randomised after written informed consent obtainment. In general, patients with proximal femur fracture will be operated within 48 hours of hospital admission based on guidelines set by the Dutch Healthcare Inspectorate (in Dutch: Inspectie voor de Gezondheidszorg). Therefore, it is not possible to give patients more than a day to consider participation. However, the intervention is non-invasive and not associated with any risks or adverse events. As beneficial effects of music on disruptive behaviour and cognition in patients with dementia have been reported, patients with dementia who underwent surgery for proximal femur fracture are not excluded from study participation, although written informed consent by the proxy is necessary (online supplemental file 2). The information folders for patient and proxy and informed consent forms follow the standard template outlined by the Central Committee on Research Involving Human Subjects, the competent authority for research in the Netherlands and the Dutch Clinical Research Foundation. Patients with hearing aids can also readily participate, which has been consulted with the Erasmus MC Auditory Centre.

Inclusion criteria
1. Patients with a proximal femur fracture undergoing surgical treatment.
2. Age ≥65 years old.
3. Provision of written informed consent by patient or proxy.

Exclusion criteria
1. Additional serious injuries or additional surgical procedures that may affect any of the outcome parameters.
2. Simultaneous bilateral hip fracture.
Secondary outcome measures are

- Postoperative pain, assessed using an 11-point Numerical Rating Scale (NRS), in which 0 implies no pain and 10 implies the worst pain possible.
- Anxiety, assessed using the Six-Item State-Trait Anxiety Inventory (STAI-6). Feelings of anxiety are reported on a 4-point Likert scale for each item, with a score between 2 and 8 points for each questionnaire. Scoring is achieved by reverse scoring the three positive items, summing all six scores and multiplying the total score by 20/6. A higher score correlates to a higher level of anxiety. The State-Trait Anxiety Inventory (STAI), consisting of two 20-item subscale questionnaires, is one of the most frequently used anxiety questionnaires in clinical research. The state subscale measures situation-related anxiety, anxiety at the very moment, while the trait subscale measures disposition-related anxiety, anxiety as a general personal characteristic trait. A major drawback of the STAI is its length, especially in a study population of elderly patients with frequent cognitive impairment, pain and opioid requirement. In order to increase compliance and minimise unanswered items, the six-item short form of the STAI state by Marteau and Bekker will be used. The STAI-6 has a high internal reliability and correlation with the full-form STAI. has been used in clinical research in elderly patients and has been validated in Dutch.
- Medication use, consisting of intraoperative and postoperative opioid medication, as well as postoperative benzodiazepines and postoperative antipsychotic medication for the treatment of delirium. Data will be collected from the electronic patient file. Analgesic opioid medication will be converted to milligrams of morphine equivalents (1 mg ME=1 mg parenteral morphine).
- Postoperative complication rate. Data will be collected from the electronic patient database and classified according to the Clavien-Dindo classification.
- Neurohormonal stress response, assessed by measuring serum cortisol. An increased stress response after surgery has been associated with an increased risk of postoperative delirium. The duration until peak cortisol level depends on the surgical severity and is an indicator of intrinsic physiological stress. Peak levels of cortisol are observed 4 hours after start of surgery in moderate and after 8 hours in major surgical procedures. Proximal femur fracture surgery is generally classified as a major surgical procedure. Therefore, the second serum cortisol will be drawn 6 hours after the first sample. This will be combined with the blood draw postoperatively for the postoperative serum haemoglobin measurement, which is part of standard surgical care.
- Hospital length of stay in days, as calculated from the hospital admission date until declared ‘medically ready for discharge’ by the attending physician as recorded in the patient’s medical file. Also, the full length of stay until the actual discharge from hospital will be assessed.
- Thirty-day mortality, as calculated from the date of admission.
- Nursing home length of stay in days, as calculated from nursing home admission date until discharge.
- Ninety-day readmission, as calculated from the date of admission.
- Ninety-day functional ability to perform daily living activities, which will be assessed during standard postoperative outpatient visit 3 months postoperatively using the Katz Index of Activities of Daily Living (Katz-ADL6). This six-item instrument assesses basic activities of daily living in six functions, with a total
score of 6 indicating full function and a score of 2 or less indicating severe functional impairment.58 ▶ Through an economic evaluation, the cost-effectiveness of the music intervention will be investigated using the method of cost-effectiveness analysis (CEA). The evaluation will be conducted from a healthcare perspective, with a time horizon of 90 days. It will make a comparison between the intervention and the control group by identifying, measuring, and valuing the costs and patient outcomes of both treatment strategies. The costs will include costs of the initial hospital admission (either on the ward or on the intensive care unit), primary surgery and additional procedures (including surgical reinterventions), medications, diagnostic imaging, in-hospital consultations, and costs for headphones and sound equipment. The analysis will take into account costs after hospital discharge, including costs of outpatient consultations, visits to the emergency room, consultations with the general practitioner, home care and nursing home admissions. Data on resource consumption will be collected from the electronic patient database and using a custom follow-up questionnaire. These data will then be combined with unit costs to generate patient-level costs. Costs of productivity losses will be ignored in this study, because these are expected to be minor, given the age range of the patients. Regarding patient outcomes, the CEA will consider the occurrence of delirium (as defined above). An incremental cost-effectiveness ratio (ICER) will be calculated as the difference in cost between the two treatment strategies divided by the difference in effectiveness, unless one treatment dominates the other (ie, has lower costs and greater effects). This ICER will be expressed as incremental costs per case of delirium prevented.

Additional study parameters assessed will be patient demographic characteristics, preoperative medication use, medical and surgical patient history, living situation prior to hospital admission, education level, injury and treatment characteristics, and music preferences and its importance in daily life. Cognitive functioning, a prominent risk factor for delirium,49 will be screened preoperatively using the Mini-Cog, a three-item screening questionnaire with high correlation to cognitive functioning assessment by the Mini-Mental State Examination.50–51

Study intervention
The music group will listen to music preoperatively, intraoperatively and postoperatively during the first 5 days after surgery. The preoperative music intervention will be ideally at least 15 min, as a relatively short exposure time seems to already have an effect.56 The intraoperative music intervention will start after anaesthesia induction until the patient chooses to remove the headphone in the recovery room. Postoperatively, the music group will listen to music two times per day for 30 min, starting from the first until the fifth postoperative day or until patient discharge. Previous studies have reported noise levels exceeding 100 decibels adjusted during surgery.52 Noise pollution during surgery is possibly associated with a negative effect on patient outcome,53 with higher noise levels reportedly increasing postoperative complications rate and stress hormone levels.54–56 Therefore, the control group will receive standard patient care and in addition wear headphones intraoperatively without music in order to avoid possible criticism that the observed effects are solely due to noise reduction and not through music. Before and after surgery, noise levels are generally quite lower compared with during surgery.53 A recent study reported that awake patients might have increased anxiety due to wearing headphones,57 which is also the reason why noise-cancelling headphones blocking all ambient noise are not used.

The music intervention consists of preselected music divided in four playlists (classical, jazz and blues, pop and Dutch music) providing approximately 30 hours of music using a tablet. Patients are allowed to choose music from these list, as the largest beneficial effects were previously observed when patients selected music from a preselected playlist.25 Moreover, it is unlikely that patients with a proximal femur fracture admitted through the emergency department after transport by ambulance will bring their own favourite music. Music was selected by a panel of five research physicians with extensive knowledge of perioperative music, based on literature recommendations and music used in previous studies. Care was taken to choose popular music from the patients’ youth and early adulthood (50s–80s) which would likely be familiar to the patient, as a familiar environment can reduce the occurrence of delirium.58 Consent was obtained from the music copyright managing organisations in the Netherlands, Buma Association and Stemra Foundation (Dutch: Vereniging Buma en Stichting Stemra), to use recorded music for study research purposes.

The Lenovo Tab E7 16GB and disposable HP 112 Fetum medically approved headphones will be used as music devices, along with the free AIMP audio player, which are easy to use and require minimal effort to select the preferred music list. The tablet also allows for magnification in order to assist visually impaired participants to choose the music.

Study procedures
A timeline detailing study procedures and outcome measures is presented in figure 1. After signing informed consent and computerised randomisation, the Mini-Cog will be administered and baseline NRS for pain and STAI-6 will be filled out also by all participants, followed by preoperative geriatric consult and DOS scores as part of standard care. A custom-made demographic questionnaire on preoperative living situation, education level and music will be provided as well.

The preoperative music intervention for the music group will start from the surgical ward when the patient
is called up for surgery and continue until arrival in the operating room, whereas the control group will receive standard care preoperatively. The anaesthesiologist and surgical team will be free to decide whether general or locoregional anaesthesia will be used, as well as the anaesthesia regimen, reflecting daily clinical practice. Beneficial effects of music on postoperative pain and opioid requirement have been observed during both general and locoregional anaesthesia, even when music is solely played intraoperatively when compared with headphones without music. Preferably, anaesthesia administration will be guided by using a bispectral index monitor or comparable anaesthesia depth monitoring device.

While a recent meta-analysis reported that significantly less propofol is needed to reach the same sedation level measured using bispectral index when listening to music intraoperatively, the majority of hospitals employ volatile anaesthesia for sedation regarding proximal femur fracture surgery. Therefore, the intraoperative sedative dosages are not recorded. After induction, the first cortisol blood sample will be drawn and all subjects will receive headphones. The control group will wear headphones in order to assess the music intervention and not noise reduction. All participants will wear headphones until arrival in the recovery room, where they can choose to remove them when they wish. No corticosteroids will be administered between the first and second cortisol blood sample drawing (6 hours after the first blood sample), unless this is deemed clinically necessary by the patient care team. As previously mentioned, cortisol will not be assessed in a selected group of patients participating in his trial.

For all participating patients postoperatively, the DOS will be assessed three times per day, with the geriatrician actively involved in proximal femur fracture surgery patient care. The NRS for pain will be assessed daily and postoperative opioid dosage will be administered based on the NRS and care team observations. The STAI-6 will be filled out by all participants during the first and second postoperative days. Data on the NRS for pain, DOS, postoperative medication requirement, postoperative complication rate, hospital length of stay and 30-day mortality rate will be retrieved from the electronic patient database. All participants will be followed up until 3 months postoperatively. Two questionnaires, the custom-made follow-up questionnaire and the Katz-ADL6 questionnaire, will be administered during either the outpatient follow-up visit or by phone. The follow-up questionnaire will assess nursing home length of stay, 90-day readmission rate and information needed for the economic evaluation.

Sample size calculation

Literature on the frequency of postoperative delirium in patients with proximal femur fracture who underwent surgery varies between 15% and 60%, with a recent meta-analysis reporting an accumulated prevalence of 24%. Delirium in Dutch proximal femur fracture surgery patients over 65 years of age has been observed in 19%–37% of patients. Previous, a meta-analysis assessing effectiveness of different, mostly non-pharmacological interventions reported a reduction in delirium rates of 13%. In order to assess a minimally clinical relevant reduction of 13% in delirium frequency when taking 15%–60% of delirium into account, with a power of 80%, alpha of 5% and planned two-sided testing, taking into account possible in-hospital mortality and loss-to-follow-up of 10% overall, 508 patients should be enrolled (254 per group).

Data collection and management

Clinical research assistants will be available at participating hospital sites to assist in executing study procedures and...
Monitoring, safety and auditing

An appointed monitor will develop standard procedures and details on the monitoring activities. The sponsor/investigator has a liability insurance which is in accordance with the Medical Research Involving Human Subjects Act (in Dutch: Wet Medisch Wetenschappelijk Onderzoek met Mensen (WMO)). The Medical Research Ethics Committee Erasmus MC has given dispensation from the statutory obligation to provide insurance for subjects participating in medical research, as participation in this study is considered to be without risks.

No deleterious or negative adverse side effects associated with listening to music as a perioperative intervention are known. In accordance, the investigator will report all serious adverse events to the sponsor, except for the specific serious adverse events which are considered not related to the music intervention and common in patients with proximal femur fracture who underwent surgery. A maximum sound level will be ensured to prevent hearing damage. The headphones and sound equipment will be cleaned with a damp microfibre cloth and the ear pads or buds will be replaced after use by the patient during hospital stay, in order to reuse the devices, in accordance with the Erasmus MC Infection Prevention Unit and local hospital protocols. No additional or enhanced hygiene measures will be needed concerning the use of headphones and sound equipment in the operating room complex and the same sound equipment set will be used on the ward.

Statistical analysis

Data will be analysed using the Statistical Package for the Social Sciences V.24.0 or higher. Normality of continuous data will be tested with the Shapiro-Wilk test. Homogeneity of variances will be tested using Levene’s test. A two-sided p value of <0.05 will be taken as threshold of statistical significance in all statistical tests. The analyses will be performed on an intention-to-treat basis. Should there be 5% crossovers, a per protocol analysis will also be done. If necessary, missing values will be replaced using multiple imputations following the predictive mean matching method, using 10 imputations.

Descriptive analysis will be performed in order to report the outcome measures for both treatment groups. For continuous data, the mean and SD (parametric data) or the median and percentiles (non-parametric data) will be reported per treatment group. For categorical data, numbers and frequencies will be reported per treatment group. The only exception is that costs will be reported as mean with 95% CI. The 95% CI around the mean costs will be approximated by non-parametric bootstrapping. Continuous data will be tested using Student’s t-test or the Mann-Whitney U test, as appropriate. Categorical data will be tested using the χ² or Fisher’s exact test, as applicable. Both univariable and multivariable analyses will be performed. A binary logistic regression model (for binary outcomes) or multivariable linear regression model (for continuous outcomes) will be developed, with the outcome as dependent variable and the study group (ie, intervention or control) as covariate. Patient, injury and treatment variables that differ between the groups and may confound the association of the intervention and outcome will be entered into the model. Variables will be entered into the model if univariate analysis produces a p value of 0.05 or lower. The unadjusted and adjusted ORs (for binary outcomes) and beta values (for continuous outcomes) will be reported with 95% CI. A subanalysis for all outcome measures will be performed by stratifying patients according to their age (<80 and ≥80 years).

Blinding

Patients enrolled in the MCHOPIN study will not be blinded to the music intervention. While the surgical team will be blinded intraoperatively on paper as all patients will wear headphones during surgery, in practice, it will not be possible to blind the surgical team as patients can adjust the music volume or ask for a different playlist while in the operating room or postoperatively on the surgical ward. The clinical chemist and laboratory site concerned with the analysis of the neurohormonal cortisol stress response samples will be blinded to the intervention. Also, a part of the statistical analysis, which includes the primary and almost all of the secondary outcome measures except the economic analysis, will be performed by a statistician blinded to the music intervention.

Patient and public involvement

Neither patients nor the public was involved in the study design, recruitment to and conduct of the study, nor in assessing the burden of the intervention.

ETHICS AND DISSEMINATION

This study will be conducted in accordance to the principles of the Declaration of Helsinki (64th WMA General Assembly, Fortaleza, Brazil, 2013) and in accordance to the Medical Research Involving Human Subjects Act (in Dutch: WMO). Written informed consent will be obtained from each patient or proxy.
Ethics approval and trial registration

Approval by the Medical Research Ethics Committee Erasmus MC was obtained on 8 October 2018 (MEC-2018–110 and NL64721.078.18). Local approval in the participating hospitals followed suit and the study was open for inclusion starting from 5 March 2019. The trial protocol has had no substantial amendments to the original protocol. This trial has been registered in the Dutch Trial Register.

Dissemination policy

Research data will be reported following the Consolidated Standards of Reporting Trials guidelines.64 No research data that can be traced to individual persons will be presented or published. On completion of the trial, the research team aims to publish the manuscript in a peer-reviewed journal and present results in national and international conferences. Each participating hospital will be invited to provide coauthors for a collaborator group authorship consisting of one trauma surgeon and one anaesthesiologist, provided that 15% of the total required study sample size is included at that site. All participating hospitals will be acknowledged for their participation.

DISCUSSION

Delirium is a prevalent complication in in-hospital elderly patients and is associated with prolonged hospitalisation due to an increased risk of postoperative complications and mortality. It also leads to long-term cognitive and functional impairment.3 6 7 10 11 Therefore, an increasing research interest in delirium prevention and treatment has developed over the past two decades. Delirium prevention is currently a healthcare quality indicator in many countries worldwide.65 Several non-pharmacological multimodal intervention programmes have reported beneficial results on reducing delirium, especially since the pharmacological prevention and treatment of delirium remain somewhat controversial.3 16 17 66 Given the multifactorial factors involved in delirium development, current guidelines consist of both multimodal pharmacological and non-pharmacological interventions. While no clinical useful biomarker for delirium has currently been identified yet,67 serum cortisol reportedly has delirious effects when increased.68–71 It has been theorised that overstimulation of the hippocampus, rich in glucocorticoid receptors and therefore susceptible for cortisol and stress, plays a role in delirium development.72 Given that perioperative music can attenuate the neurohormonal cortisol stress response,26 combined with the significant beneficial effects of perioperative music on postoperative pain, anxiety, intraoperative sedative requirement and postoperative opioid usage,25 26 the multicentre, randomised controlled, clinical MCHOPIN trial will assess the effect of perioperative recorded music on postoperative delirium, patient outcome and recovery in elderly patients with proximal femur fracture who underwent surgery.

An exhaustive literature search with a biomedical information specialist was performed on 16 October 2020 in order to assess current literature on perioperative music and postoperative delirium in adult surgical patients. Only four randomised controlled trials evaluated the effect of music on postoperative cognitive functioning and delirium. McCaffrey and Locsin et al. reported significant lower acute confusion episodes in two trials with 190 elderly patients undergoing elective hip or knee surgery.90 33 However, confusion was ascertained by reading the nurse’s narrative notes without use of screening tools for delirium recognition. Two other studies observed significantly lower rates of postoperative acute confusion ascertained using the validated NEECHAM Acute Confusion Scale when patients listened to music postoperatively compared with standard care. Sample sizes were relatively small, with only 22 and 60 patients who had elective hip and knee surgery included.52 33

In the MCHOPIN study, the DOS score will be used to proactively screen for delirium in all participants during each nursing shift.33 37 Given that delirium is often not recognised or misdiagnosed, a strong point of this trial is that all participating hospitals are high-volume centres which actively involve the geriatrician in the care of all admitted proximal femur fracture surgery patients. Both patients and practitioners will not be blinded, as the beneficial effects of perioperative music seem largest when music is applied before, during and after surgery instead of only intraoperatively during general anaesthesia.25 26 Also, a significant portion of patients with proximal femur fracture who underwent surgery are operated on while receiving locoregional anaesthesia. We believe it acceptable that no blinding is applied, as patients cannot be blinded in many surgical trials. Only 3% and 37% of practitioners and patients were blinded for cortisol and stress, plays a role in delirium development.72 Given that perioperative music can attenuate the neurohormonal cortisol stress response,26 combined with the significant beneficial effects of perioperative music on postoperative pain, anxiety, intraoperative sedative requirement and postoperative opioid usage,25 26 the multicentre, randomised controlled, clinical MCHOPIN trial will assess the effect of perioperative recorded music on postoperative delirium, patient outcome and recovery in elderly patients with proximal femur fracture who underwent surgery.

undergoing proximal femur fracture surgery was chosen because of the prevalent occurrence of postoperative delirium and high levels of postoperative pain and stress. Results of this trial will give insight in reduction of delirium in a prevalent and vulnerable patient group, as well as clarify the relation between neurohormonal stress response to surgery activity, the occurrence of delirium and postoperative complication rate.

TRIAL STATUS
The current protocol is V.3.0, dated 15 August 2018. The current protocol is V.3.0, dated 15 August 2018. The trial was originally expected to continue until December 2021 at time of inception, but is now projected to continue until 2022. The study is open for patient inclusion.

Subject information for participation in medical scientific research

Effect of music on the clinical outcome after hip fracture operations (MCHOPIN): a multicenter randomized controlled trial

Introduction

Dear Sir/Madam,

You are asked to take part in a medical-scientific study (the MCHOPIN study). Participation is voluntary. Participation requires your written consent. You have received this letter because you have broken your hip and will undergo surgery. Before you decide whether you want to participate in this study, you will be given an explanation about what the study involves. Please read this information carefully and ask the investigator for an explanation if you have any questions. You can also ask the independent expert, who is mentioned at the end of this document, for additional information. You may also discuss it with your partner, friends or family. Additional information about participating in a study can be found in the enclosed general brochure on medical research.

1. General information

This study has been set up by the Erasmus MC and will be conducted by trauma surgeons in various hospitals in the Netherlands. For this study, 508 study subjects are required. The Medical Research Ethics Committee (MREC) Erasmus MC has approved this study. General information about the assessment of research can be found in the general brochure on medical research.

2. Purpose of the study

Scientific research has shown that music during and around surgery can have a beneficial effect on pain and anxiety. The purpose of this study is to assess the effect of music during and around surgery for a broken hip. Among other
things, the effect of music on delirium, pain, anxiety, medication requirement, complications after surgery, stress response of the body, length of hospital stay and / or length of nursing home stay and daily functional ability after surgery will be investigated.

3. Background of the study
It is known that 25-40% of patients with a broken hip in the Netherlands develop delirium, a sudden episode of confusion and disturbance of consciousness. This can lead to other complications after surgery, a prolonged hospitalization and a negative effect on recovery. Therefore, measures are taken to prevent delirium. For example, this is done by treating or reducing risk factors, like pain and stress. Because of the beneficial effect of music on pain and stress, we would like to assess whether music can reduce the occurrence of delirium. The benefit of music compared to other ways of treatment is that it is easy and durable, without side effects.

4. What participation involves
Your participation will last until 3 months after your surgery.

Treatment
In this study, half of the subjects will listen to music before, during and after surgery during hospital stay. The other half of the subjects will not listen to music. The music consists of a preselected music list by the investigators, and subjects of the music group will be allowed to choose from this list. It will be determined by drawing lots whether or not you will listen to music. Additional information about this can be found in the enclosed general brochure on medical research.

If you have drawn the music group, you will receive a headphone and listen to music before surgery during 15 minutes. If you are using a hearing aid, you will be asked to take it off and to adjust the music volume to a pleasant level. During surgery, you will listen to music until leaving the recovery room. After surgery, you will listen to music twice a day for 30 minutes during the first 5 days of your hospital stay after surgery. If you have not drawn the music group, you will wear a headphone without music 15 minutes before surgery.
until leaving the recovery room. You are not allowed to listen to music during the first 5 days of your hospital stay after surgery, if you have not drawn the music group.

**Visits and measurements**
An additional time investment from your part is required. During your hospital stay, you will be asked:

- to fill in a pain score once a day, which takes less than 1 minute to complete.
- to fill in once a 6-item questionnaire on your level of education, living situation and the role of music in your life, which takes approximately 5 minutes to complete.
- to fill in a 6-item questionnaire on anxiety once before and 2 times after surgery, which takes approximately 5 minutes to complete.
- to fill in a 3-item questionnaire on cognition once before surgery. This questionnaire will be administered to you by the attending physician or investigator.
- for 2 blood samples to measure the cortisol level, a measurement for the body’s stress response. The first sample will be drawn at the start of surgery. For the second blood sample, an extra tubule of blood will be drawn for this study during a routine blood collection after surgery for a broken hip.

During the regular outpatient hospital visit 3 months after surgery, you will be asked:

- to fill in once an 8-item follow-up questionnaire on whether or not you have been readmitted to hospital, which takes approximately 5 to 10 minutes to complete.
- to fill in once a 6-item questionnaire on daily functional ability, which takes approximately 5 minutes to complete.

Furthermore, the investigator and investigator assistant will collect data from the electronic patient database to answer the research question of this study. This consists of personal data, like age and data on your surgical procedure, medication use, complications and hospital stay. If necessary, one of the
investigators will contact the hospital pharmacy, to assess which medicines you received during the hospital stay. If you stay in a nursing home or care home after discharge from hospital, one of the investigators will contact it for information on the duration of your stay.

**Other than standard care**

If you have drawn the music group, you will listen to music during and around your surgery, both groups will fill in the afore mentioned questionnaires and pain scores and blood will be drawn twice. If you have drawn the control group, you are not allowed to listen to music during and around your surgery and the first five days after your surgery, even though you might have done this normally. The daily care during your hospital stay remains unchanged. This study will end after your regular outpatient hospital visit, 3 months after your discharge. No additional study-related visits are required. If no outpatient visit is planned at that time after your operation, one of the investigators will contact you.

**5. What is expected of you**

In order to carry out the study properly, it is important that you follow the study instructions.

The study instructions require that you:

- listen to music before, during and the first 5 days after surgery only at the aforementioned moments if you have drawn the music group.
- do not listen to music before surgery, during surgery and during the first 5 days after surgery if you have not drawn the music group.
- do not participate in another medical study.
- fill in the afore mentioned questionnaires and pain scores, and that twice a tubule of blood will be drawn.

It is important that you contact the investigator:

- if you are admitted or treated in an hospital
- if you no longer want to participate in the study.
- if your contact details change.
6. Possible side effects, complications and discomforts
The music intervention is safe and has no known side effects or complications. To prevent hearing loss, a maximum sound level has been set. Drawing blood can hurt and can in some cases lead to bruising.

7. Possible advantages and disadvantages
It is important that you properly weigh up the possible benefits and disadvantages before you decide to join. Your participation can contribute to more knowledge on delirium and the use of music in health care.

Music could potentially have a beneficial effect on delirium, pain and anxiety after surgery, but this is not certain. Disadvantages of participating in this study can be:

- the extra time it will require
- the instructions you need to follow
- not being able to listen to music during the first 5 days after your surgery
- filling in the questionnaires and pain scores
- drawing of blood

All these aspects have been described above under points 4, 5 and 6.

8. If you do not want to participate or you want to stop participating in the study
It is up to you to decide whether or not to participate in the study. Participation is voluntary. If you do not want to participate, you will be treated as usual for a broken hip. If you do participate in the study, you can always change your mind and decide to stop, at any time during the study. You will then be treated as usual for a broken hip. You do not have to say why you are stopping, but you do need to tell the investigator immediately. The data collected until that time will still be used for the study.

If there is any new information about the study that is important for you, the investigator will let you know. You will then be asked whether you still want to continue your participation.
9. End of the study
Your participation in the study stops when:
• you have completed the outpatient visit and the measurements as
described under point 4
• you choose to stop
• the investigator considers it best for you to stop
• the sponsor (Erasmus MC), the government or Medical Research Ethics
Committee, decides to stop the study.

The study is concluded once all the participants have completed the study.

10. Usage and storage of your data and bodily material
Your personal data and bodily material will be collected, used and stored for
this study. This concerns data such as your name, address, date of birth and
data about your health. Also, blood is required for this study. The collection,
use and storage of your data and your bodily material are required to answer
the questions asked in this study and to publish the results. We ask your
permission for the use of your data and bodily material.

Confidentiality of your data and bodily material
To protect your privacy, your data and your bodily material will be given a
code. Your name and other information that can directly identify you, will be
omitted. Data can only be traced back to you with the encryption key. The
investigator and investigator assistants are the only people who will know
which code you have. This is necessary, as they will have to collect
information from the electronic patient database, questionnaires and bodily
material. The data and bodily material that is sent to the sponsor will only
contain the code, not your name or other data with which you can be
identified. The key to the code will stay with the investigator. The data cannot
be traced back to you in reports and publications about the study.

Access to your data for verification
Some people can access all your data at the research location. Including the
data without a code. This is necessary to check whether the study is being
conducted in a good and reliable manner. Persons who have access to your data for review are members of the research team, a monitor working for the sponsor of the study, and national supervisory authorities, for example, the Healthcare and Youth Inspectorate. They will keep your data confidential. We ask you to consent to this access.

Retention period of your data and bodily material
Your data must be kept for 15 years at the research location (Erasmus MC). Your bodily material will be destroyed immediately after use.

Withdrawing consent
You can withdraw your consent to the use of your personal data at any time. This applies to this study. The study data collected until the moment you withdraw your consent will still be used in the study. Your bodily material will be destroyed after your consent has been withdrawn. If measurements have already been made with that bodily material, then this data will still be used.

More information about your rights when processing data
For general information about your rights when processing your personal data, you can consult the website of the Dutch Data Protection Authority.

If you have questions about your rights, please contact the person responsible for the processing of your personal data. For this study, that is: Erasmus MC. See Appendix A for contact details and website.

If you have questions or complaints about the processing of your personal data, we advise you to first contact the research location. You can also contact the Data Protection Officer of the Erasmus MC (See Appendix A. Contact details) or the Dutch Data Protection Authority.

Registration of the study
Information about this study is included in a list of medical-scientific studies namely the Dutch trial registry (www.trialregister.nl). It does not contain any information that can be traced to you. After the study, the website may display
a summary of the results of this study. You can find this study under MCHOPIN.

11. Study subject insurance
This study is not associated with any additional risks for you. The MREC Erasmus MC has therefore decided that the sponsor does not need to take out additional insurance.

12. Informing GP and contact with the hospital pharmacy
We will always send your GP a letter to let them know that you are participating in the study. This is for your own safety. If you do not agree to this, you cannot participate in this study. You cannot participate in the study if you do not have a GP.

During this study, the effect of music on medication use will be assessed. Therefore, the investigators will contact the hospital pharmacy to ask about your medication use. You cannot participate in this study if you do not want this.

13. No Compensation for participation
Participation in this study and use of the sound equipment is free of charge for you. You will not be paid for your participation in this study.

14. Any questions?
If you have any questions, please contact the study team. If you would like any independent advice about participation in this study, you may contact the independent doctor. He knows about the study but is not involved in it. If you have any complaints, you may contact the complaint officer at your hospital. All the relevant details can be found in Appendix A: Contact details.

15. Signing the consent form
When you have had sufficient time for reflection, you will be asked to decide on participation in this study. If you give permission, we will ask you to confirm this in writing on the appended consent form. By your written permission you indicate that you have understood the information and consent to participation.
in the study. The signature sheet is kept by the investigator. You will get a copy or a second copy of this consent form.

Thank you for your attention.

16. Appendices to this information
A. Contact details
B. Informed Consent Form subject
C. Medical Scientific Research Brochure. General Information for Study Subjects (version 01-03-2017)
Appendix A: contact details for Erasmus MC

Principle investigator:
Prof. dr. M.H.J. Verhofstad, trauma surgeon  Tel. no.: 010-7031050
Available during office hours. You can contact the general number of the hospital (tel. no. 010-7040704) outside of office hours and ask for the attending of the (trauma)surgery department.

Coordinating investigator:
Mr. V.X. Fu, research physician Erasmus MC  Tel. no.: 06-21128074
Available during and outside of office hours.

Independent doctor:
Prof. dr. H.J.M. Verhagen, surgeon Erasmus MC  Tel. no.: 010-7040112
Available during office hours.

Complaints:
Secretariaat Klachtenopvang Erasmus MC  Tel. no.: 010-7033198
Available during office hours.
P.O. Box: Erasmus MC, attn. secretariaat Klachtenopvang
Antwoordnummer 55, 3000 WB Rotterdam
E-mail: klachtenopvang@erasusmc.nl

Data Protection Officer of Erasmus MC:
Data Protection Officer Erasmus MC  Tel. no.: 010-7034986
Secretariat Department of Legal Affairs
Available during office hours.

Appendix B: Subject Consent Form

Effect of music on the clinical outcome after hip fracture operations (MCHOPIN): a multicenter randomized controlled trial

- I have read the subject information form. I was also able to ask questions. My questions have been answered to my satisfaction. I had enough time to decide whether to participate.
- I know that participation is voluntary. I know that I may decide at any time not to participate after all or to withdraw from the study. I do not need to give a reason for this.
- I give permission for my GP to be informed about my participation in this study.
- I give permission for the collection and use of my data and blood to answer the research question in this study.
- I give permission for information to be requested from the nursing home or care home in the way and for the purpose stated in the information sheet.
- I give permission for information to be requested from the hospital pharmacy in the way and for the purpose stated in the information sheet.
- I know that some people may have access to all my data to verify the study. These people are listed in this information sheet. I consent to the inspection by them.
- I consent to my data being stored at the research location (Erasmus MC) for another 15 years after this study.
- I want to participate in this study.
The study subject will receive the full information sheet, together with a copy of the signed consent form.

| Name of the study subject: | ................................................. |
| Date:                     | __ / __ / __                          |
| Signature:                | ................................................. |

I hereby declare that I have fully informed this study subject about this study. If information comes to light during the course of the study that could affect the study subject's consent, I will inform him/her of this in a timely fashion.

| Name of investigator (or his/her representative): | ................................................. |

Subject information for participation in medical scientific research

Effect of music on the clinical outcome after hip fracture operations (MCHOPIN): a multicenter randomized controlled trial

Dear Sir/Madam,

You are asked as legal representative to give consent on behalf of your relative/family member to take part in a medical-scientific study (the MCHOPIN study). If a patient is unable to give consent, the legal representative is asked for substitute consent. Participation is voluntary. Participation requires your written consent.

You have received this letter because your relative/family member has broken his/her hip and will undergo surgery. Before you decide whether you want your relative/family member to participate in this study, you will be given an explanation about what the study involves. Please read this information carefully and ask the investigator for an explanation if you have any questions. You can also ask the independent expert, who is mentioned at the end of this document, for additional information. You may also discuss it with your partner, friends or family. Additional information about participating in a study can be found in the enclosed general brochure on medical research.

1. General information
This study has been set up by the Erasmus MC and will be conducted by trauma surgeons in various hospitals in the Netherlands. For this study, 508 study subjects are required. The Medical Research Ethics Committee (MREC) Erasmus MC has approved this study. General information about the assessment of research can be found in the general brochure on medical research.
2. Purpose of the study
Scientific research has shown that music during and around surgery can have a beneficial effect on pain and anxiety. The purpose of this study is to assess the effect of music during and around surgery for a broken hip. Among other things, the effect of music on delirium, pain, anxiety, medication requirement, complications after surgery, stress response of the body, length of hospital stay and / or length of nursing home stay and daily functional ability after surgery will be investigated.

3. Background of the study
It is known that 25-40% of patients with a broken hip in the Netherlands develop delirium, a sudden episode of confusion and disturbance of consciousness. This can lead to other complications after surgery, a prolonged hospitalization and a negative effect on recovery. Therefore, measures are taken to prevent delirium. For example, this is done by treating or reducing risk factors, like pain and stress. Because of the beneficial effect of music on pain and stress, we would like to assess whether music can reduce the occurrence of delirium. The benefit of music compared to other ways of treatment is that it is easy and durable, without side-effects.

4. What participation involves
If your relative/family member participates, participation will last until 3 months after his/her surgery.

Treatment
In this study, half of the subjects will listen to music before, during and after surgery during hospital stay. The other half of the subjects will not listen to music. The music consists of a preselected music list by the investigators, and subjects of the music group will be allowed to choose from this list. It will be determined by drawing lots whether or not your relative/family member will listen to music. Additional information about this can be found in the enclosed general brochure on medical research.

If your relative/family member has drawn the music group, he/she will receive a headphone and listen to music before surgery during 15 minutes.
relative/family member is using a hearing aid, he/she will be asked to take it off and to adjust the music volume to a pleasant level. During surgery, your relative/family member will listen to music until leaving the recovery room. After surgery, he/she will listen to music twice a day for 30 minutes during the first 5 days of his/her hospital stay after surgery. If your relative/family member has not drawn the music group, he/she will wear a headphone without music 15 minutes before surgery until leaving the recovery room. He/she is not allowed to listen to music during the first 5 days of his/her hospital stay after surgery, if your relative/family member has not drawn the music group.

**Visits and measurements**

An additional time investment from the part of your relative/family member is required. During the hospital stay of your relative/family member, he/she will be asked:

- to fill in a pain score once a day, which takes less than 1 minute to complete.
- to fill in once a 6-item questionnaire on his/her level of education, living situation and the role of music in his/her life, which takes approximately 5 minutes to complete.
- to fill in once a 6-item questionnaire on anxiety before and 2 times after surgery, which takes approximately 5 minutes to complete.
- to fill in a 3-item questionnaire on cognition once before surgery. This questionnaire will be administered to your relative/family member by the attending physician or investigator.
- for 2 blood samples to measure the cortisol level, a measurement for the body’s stress response. The first sample will be drawn at the start of surgery. For the second blood sample, an extra tubule of blood will be drawn for this study during a routine blood collection after surgery for a broken hip.

During the regular outpatient hospital visit 3 months after surgery, your relative/family member will be asked:
• to fill in once an 8-item follow-up questionnaire on whether or not he/she has been readmitted to hospital, which takes approximately 5 to 10 minutes to complete.
• to fill in once a 6-item questionnaire on daily functional ability, which takes approximately 5 minutes to complete.

Furthermore, the investigator and investigator assistant will collect data from the electronic patient database to answer the research question of this study. This consists of personal data, like age and data on his/her surgical procedure, medication use, complications and hospital stay. If necessary, one of the investigators will contact the hospital pharmacy to assess which medicines your relative/family member received during his/her hospital stay. If your relative/family member stays in a nursing home or care home after discharge from hospital, one of the investigators will contact it for information on the duration of his/her stay.

Other than standard care
If your relative/family member has drawn the music group, he/she will listen to music during and around surgery, both groups will fill in the afore mentioned questionnaires and pain scores and blood will be drawn twice. If your relative/family member has drawn the control group, he/she is not allowed to listen to music during and around his/her surgery and the first five days after his/her surgery, even though he/she might have done this normally. The daily care during hospital stay remains unchanged. This study will end after the regular outpatient hospital visit, 3 months after hospital discharge. No additional study-related visits are required. If no outpatient visit is planned at that time after the operation, one of the investigators will contact you and your relative/family member.

5. What is expected of your relative/family member
In order to carry out the study properly, it is important that your relative/family member follows the study instructions.
NL64721.078.18 (MCHOPIN study)

The study instructions require that he/she:

- listens to music before, during and the first 5 days after surgery only at
  the aforementioned moments if he/she has drawn the music group.
- does not listen to music before surgery, during surgery and during the
  first 5 days after surgery if he/she has not drawn the music group.
- does not participate in another medical study.
- fills in the aforementioned questionnaires and pain scores, and that
  twice a tubule of blood will be drawn.

It is important that you contact the investigator:

- if your relative/family member is admitted or treated in an hospital
- if you want your relative/family member to stop participating in this
  study
- if your contact details or the contact details of your relative/family
  member change.

6. Possible side effects, complications and discomforts

The music intervention is safe and has no known side effects or
complications. To prevent hearing loss, a maximum sound level has been set.
Drawing blood can hurt and can lead to bruising in some cases.

7. Possible advantages and disadvantages

It is important that you properly weigh up the possible benefits and
disadvantages before you decide for your relative/family member to join.
His/her participation can contribute to more knowledge on delirium and the
use of music in health care.

Music could potentially have a beneficial effect on delirium, pain and anxiety
after surgery, but this is not certain. Disadvantages of participating in this
study can be:

- the extra time it will require
- the instructions your relative/family member needs to follow
- that he/she will not be able to listen to music during the first 5 days
  after surgery
- filling in the questionnaires and pain scores
8. If you do not want your relative/family member to participate or want to stop participation in the study

It is up to you to decide whether or not your relative/family member participates in the study. Participation is voluntary. If you do not want your relative/family member to participate, he/she will be treated as usual for a broken hip. If your relative/family member does participate in the study, you can always change your mind and decide to stop, at any time during the study. He/she will then be treated as usual for a broken hip. You do not have to say why your relative/family member is stopping, but you do need to tell the investigator immediately. The data collected until that time will still be used for the study.

If there is any new information about the study that is important for you, the investigator will let you know. You will then be asked whether you still want your relative/family member to continue participating in this study.

9. Resistance of the person you represent

The person you represent may resist (refuse to cooperate) during the study. The investigator will then have to stop the study immediately. It is difficult to describe what exactly resistance is. Before the start of the study you will be given an explanation of what is considered resistance. The investigator will follow the Code of Conduct on resistance of mentally incompetent and geriatric patients.

10. End of the study

The participation of your relative/family member in the study stops when:

- he/she has completed the outpatient visit and the measurements as described under point 4
- you choose to stop
- the investigator considers it best for your relative/family member to stop
• the sponsor (Erasmus MC), the government or Medical Research Ethics Committee, decides to stop the study.

The study is concluded once all the participants have completed the study.

11. Usage and storage of data and bodily material of your relative/family member
The personal data and bodily material of your relative/family member will be collected, used and stored for this study. This concerns data such as name, address, date of birth and data about health. Also, blood is required for this study. The collection, use and storage of the data and bodily material of your relative/family member are required to answer the questions asked in this study and to publish the results. We ask your permission for the use of the data and bodily material of your relative/family member.

Confidentiality of the data and bodily material of your relative/family member
To protect the privacy of your relative/family member, his/her data and bodily material will be given a code. His/her name and other information that can directly identify your relative/family member will be omitted. Data can only be traced back to your relative/family member with the encryption key. The investigator and investigator assistants are the only people who will know which code your relative/family member has. This is necessary, as they will collect information from the electronic patient database, questionnaires and bodily material. The data and bodily material that is sent to the sponsor will only contain the code, not his/her name or other data with which your relative/family member can be identified. The key to the code will stay with the investigator. The data cannot be traced back to your relative/family member in reports and publications about the study.

Access to the data of your relative/family member for verification
Some people can access all the data of your relative/family member at the research location. Including the data without a code. This is necessary to check whether the study is being conducted in a good and reliable manner. Persons who have access to the data of your relative/family member for
review are members of the research team, a monitor working for the sponsor of the study, and national supervisory authorities, for example, the Healthcare and Youth Inspectorate. They will keep the data of your relative/family member confidential. We ask you to consent to this access.

**Retention period of the data and bodily material of your relative/family member**
The data of your relative/family member must be kept for 15 years at the research location (Erasmus MC). His/her bodily material will be destroyed immediately after use.

**Withdrawing consent**
You can withdraw your consent to the use of the personal data of your relative/family member at any time. This applies to this study. The study data collected until the moment you withdraw your consent will still be used in the study. The bodily material of your relative/family member will be destroyed after your consent has been withdrawn. If measurements have already been made with that bodily material, then this data will still be used.

**More information about the rights when processing data**
For general information about the rights when processing the personal data of your relative/family member, you can consult the website of the Dutch Data Protection Authority.

If you have questions about these rights, please contact the person responsible for the processing of the personal data of your relative/family member. For this study, that is: Erasmus MC. See Appendix A for contact details and website.

If you have questions or complaints about the processing of the personal data of your relative/family member, we advise you to first contact the research location. You can also contact the Data Protection Officer of the Erasmus MC (See Appendix A. Contact details) or the Dutch Data Protection Authority.
Registration of the study
Information about this study is included in a list of medical-scientific studies namely the Dutch trial registry (www.trialregister.nl). It does not contain any information that can be traced to your relative/family member. After the study, the website may display a summary of the results of this study. You can find this study under MCHOPIN.

12. Study subject insurance
This study is not associated with any additional risks for your relative/family member. The MREC Erasmus MC has therefore decided that the sponsor does not need to take out additional insurance.

13. Informing GP and contact with the hospital pharmacy
We will always send the GP of your relative/family member a letter to let them know that he/she is participating in the study. This is for the safety of your relative/family member. If you do not agree to this, your relative/family member cannot participate in this study. Your relative/family member cannot participate in the study if he/she does not have a GP.

During this study, the effect of music on medication use will be assessed. Therefore, the investigators will contact the hospital pharmacy to ask about medication usage. Your relative/family member cannot participate in this study if you do not want this.

14. No Compensation for participation
Participation in this study and use of the sound equipment is free of charge for you and your relative/family member. You and your relative/family member will not be paid for the participation in this study.

15. Any questions?
If you have any questions, please contact the study team. If you would like any independent advice about participation in this study, you may contact the independent doctor. He knows about the study but is not involved in it. If you have any complaints, you may contact the complaint officer at your hospital. All the relevant details can be found in Appendix A: Contact details.
16. Signing the consent form

When you have had sufficient time for reflection, you will be asked to decide on participation of your relative/family member in this study. If you give permission, we will ask you to confirm this in writing on the appended consent form. By your written permission you indicate that you have understood the information and consent to participation of your relative/family member in the study. The signature sheet is kept by the investigator. You will get a copy or a second copy of this consent form.

Thank you for your attention.

17. Appendices to this information

A. Contact details
B. Representative Informed Consent Form
C. Medical Scientific Research Brochure. General Information for Study Subjects (version 01-03-2017)
Appendix A: contact details for Erasmus MC

**Principle investigator:**
Prof. dr. M.H.J. Verhofstad, trauma surgeon  
Tel. no.: 010-7031050  
Available during office hours. You can contact the general number of the hospital (tel. no. 010-7040704) outside of office hours and ask for the attending of the (trauma)surgery department.

**Coordinating investigator:**
Mr. V.X. Fu, research physician Erasmus MC  
Tel. no.: 06-21128074  
Available during and outside of office hours.

**Independent doctor:**
Prof. dr. H.J.M. Verhagen, surgeon Erasmus MC  
Tel. no.: 010-7040112  
Available during office hours.

**Complaints:**
Secretariaat Klachtenopvang Erasmus MC  
Tel. no.: 010-7033198  
Available during office hours.  
P.O. Box: Erasmus MC, attn. secretariaat Klachtenopvang Antwoordnummer 55, 3000 WB Rotterdam  
E-mail: klachtenopvang@erasusmc.nl

**Data Protection Officer of Erasmus MC:**
Data Protection Officer Erasmus MC  
Tel. no.: 010-7034986  
Secretariat Department of Legal Affairs  
Available during office hours.

Appendix B: Representative Informed Consent Form

Effect of music on the clinical outcome after hip fracture operations (MCHOPIN): a multicenter randomized controlled trial

I have been asked to consent to the following person participating in this medical-scientific study:

| Name of the study subject: | .......................................................... |
| Date of birth: | __/__/__ |

- I have read the information sheet for the study subject. I was also able to ask questions. My questions have been answered to my satisfaction. I have had enough time to decide whether this person will participate.
- I know that participation is voluntary. I also know that I can decide at any time that this person will not participate after all. I do not need to give a reason for this decision.
- I give permission for this person’s GP to be informed about this person’s participation in this study.
- I give permission for the collection and use of data and blood of this person to answer the research question in this study.
- I give permission for information to be requested from the nursing home or care home in the way and for the purpose stated in the information sheet.
- I give permission for information to be requested from the hospital pharmacy in the way and for the purpose stated in the information sheet.
- I know that some people may have access to all the data of this person to verify the study. These people are listed in this information sheet. I consent to the inspection by them.
- I consent to the data being stored at the research location (Erasmus MC) for another 15 years after this study.
- I agree to this person’s participation in this study.
**Name of legal representative:**  
………………………………………

**Relationship with the study subject:**  
………………………………………

**Date:**  
__/__/__

**Signature:**  
………………………………………

I hereby declare that I have fully informed this/these person(s) about this study. If information comes to light during the course of the study that could affect the legal representative's consent, I will inform him/her of this in a timely fashion.

**Name of investigator (or his/her representative):**  
………………………………………

**Date:**  
__/__/__

**Signature:**  
………………………………………

**Additional information was given by**  

**Name:**  
………………………………………

**Job Title:**  
………………………………………

**Date:**  
__/__/__

**Signature:**  
………………………………………

The representative will receive the full information sheet, together with a copy of the signed consent form.
