ABSTRACT

Objectives: In the International Classification of Diseases, Tenth Edition (ICD-10), hypochondriasis (illness anxiety disorder) and dysmorphophobia (body dysmorphic disorder) share the same diagnostic code (F45.2). However, the Swedish ICD-10 allows for these disorders to be coded separately (F45.2 and F45.2A, respectively), potentially offering unique opportunities for register-based research on these conditions. We assessed the validity and reliability of their ICD-10 codes in the Swedish National Patient Register (NPR).

Design: Chart review.

Methods: Six hundred individuals with a diagnosis of hypochondriasis or dysmorphophobia (300 each) were randomly selected from the NPR. Their medical files were requested from the corresponding clinics, located anywhere in Sweden. Two independent raters assessed each file according to ICD-10 definitions and Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR) and Fifth Edition (DSM-5) criteria. Raters also completed the Clinical Global Impression–Severity (CGI-S) and the Global Assessment of Functioning (GAF).

Primary outcome measure: Percent between-rater agreement and positive predictive value (PPV). Intraclass correlation coefficients for the CGI-S and the GAF.

Results: Eighty-four hypochondriasis and 122 dysmorphophobia files were received and analyzed. The inter-rater agreement rate regarding the presence or absence of a diagnosis was 95.2% for hypochondriasis and 92.6% for dysmorphophobia. Sixty-seven hypochondriasis files (79.8%) and 111 dysmorphophobia files (91.0%) were considered ‘true positive’ cases (PPV=0.80 and PPV=0.91, respectively). CGI-S scores indicated that symptoms were moderately to markedly severe, while GAF scores suggested moderate impairment for

1
2
3 hypochondriasis and moderate to serious impairment for dysmorphophobia. CGI-S and GAF
4
5 inter-rater agreement was good for hypochondriasis and moderate for dysmorphophobia.
6
7

8 **Conclusions:** The Swedish ICD-10 codes for hypochondriasis and dysmorphophobia are
9
10 sufficiently valid and reliable for register-based studies. The results of such studies should be
11
12 interpreted in the context of a possible over-representation of severe and highly impaired
13
14 cases in the register, particularly for dysmorphophobia.

dysmorphic disorder, validity, reliability, epidemiology.

STRENGTHS AND LIMITATIONS OF THIS STUDY

- Randomly drawn sample of hypochondriasis and dysmorphophobia cases from all over Sweden.
- Thorough review of medical files by at least two independent expert raters.
- Good inter-rater reliability.
- No control diagnostic group.
- Limited number of cases and potential risk of selection bias.

INTRODUCTION

The National Board of Health and Welfare is a Swedish governmental agency that in 1964 established the National Patient Register (NPR), a health register with individual-level reporting of clinical diagnoses which plays a crucial role in Swedish register-based epidemiological research[1]. The quality of the research conducted on NPR data is highly dependent on the diagnostic validity of the diagnostic codes[2]. Diagnoses in the NPR are coded according to the Swedish International Classification of Diseases (ICD) system, which was adapted from the World Health Organization ICD classification system[1]. The validity of a wide range of ICD diagnostic codes in the Swedish NPR differs between diagnoses, but is generally high[1]. Several diagnostic codes for psychiatric disorders have been examined and generally shown to be sufficiently valid and reliable for research purposes[3-8].

Hypochondriasis (also known as illness anxiety disorder) and dysmorphophobia (also known as body dysmorphic disorder) are two chronic and often severe psychiatric disorders associated with significant suffering and a high level of functional impairment[9]. Their estimated prevalence is 1-2% for hypochondriasis[10] and around 2% for dysmorphophobia[11, 12]. In the international version of the ICD-10[13], hypochondriasis and dysmorphophobia are classed as somatoform disorders and share the same diagnostic code (F45.2). It is therefore not possible to separate the two disorders for clinical or research purposes[13]. By contrast, the Swedish version of the ICD-10 includes an additional code that allows clinicians to separately diagnose these two disorders. Specifically, hypochondriasis is coded F45.2, whereas dysmorphophobia is coded F45.2A[14]. This distinction is in line with the most recent classification of these disorders in the ICD-11, which considers them as two separate, but closely related diagnoses within the obsessive-compulsive spectrum[9, 15-18]. Similarly, in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), hypochondriasis (illness anxiety disorder) and dysmorphophobia (body dysmorphic

1
2
3 disorder) are two different disorders, although they appear under separate chapters
4
5 (somatoform and obsessive-compulsive and related disorders, respectively)[9, 19, 20]. Thus,
6
7 the Swedish “anomaly” in the ICD-10 potentially offers a unique opportunity for register-
8
9 based studies on these disabling psychiatric conditions. However, the validity and reliability
10
11 of these diagnostic codes has not yet been established.
12
13
14

15 This study employed a chart review methodology to establish the validity of the
16
17 Swedish ICD-10 codes for hypochondriasis and dysmorphophobia in the NPR with the aim to
18
19 assess whether these codes are suitable for future register-based studies.

21
22
23
24

25 **METHODS**

26 **Procedures**

27
28
29 After receiving approval from the regional ethical review board in Stockholm (2016/2399-
30
31 31/5 and 2017/325-32), we requested 600 randomly selected personal identification numbers
32
33 of individuals who ever received a diagnosis of either hypochondriasis ($n=300$) or
34
35 dysmorphophobia ($n=300$) from the Swedish National Board of Health and Welfare. In
36
37 accordance with the protocol approved by the ethical review board, individual patients were
38
39 not asked for consent, as this would introduce selection biases. No weighting or other
40
41 adjustments were done to randomly select the cases.
42
43
44
45
46
47

48 For hypochondriasis, we requested 300 files with the ICD-10 code F45.2 and all its
49
50 subcodes (except for F45.2A), namely: F45.2B for nosophobia, F45.2C for cancer phobia,
51
52 F45.2D for venerophobia, and F45.2X for hypochondriasis, unspecified. For
53
54 dysmorphophobia, we requested 300 files with the ICD-10 code F45.2A. The dates of
55
56 registered diagnosis spanned from 1998 to 2016 for those with diagnoses assigned in inpatient
57
58 clinics, and from 2001 to 2016 for those with diagnoses assigned in outpatient clinics. To be
59
60

1
2
3 eligible for inclusion, a single ICD-10 diagnosis of hypochondriasis or dysmorphophobia at
4
5 any time during this time period was sufficient.
6
7

8
9 Following the procedures previously used in other validation studies by the research
10
11 group[3, 7], once the random cases had been identified, we sent written requests to the
12
13 corresponding archives or clinics, based on the hospital and medical specialty codes
14
15 associated to the cases. Cases were excluded when we could not find the associated clinic
16
17 (e.g., the clinic was no longer operative), when the clinic did not reply or declined
18
19 participation, when the diagnostic code under study was not documented in the received file
20
21 or when there was not enough information in the received file to make a diagnostic judgement
22
23 (e.g., a description of clinical symptoms was not available). **Figure 1** shows the flow for the
24
25 inclusion of cases for each diagnosis. In total, we received 84 valid cases of hypochondriasis
26
27 (including 72 cases diagnosed F45.2, hypochondriasis; one case diagnosed F45.2C, cancer
28
29 phobia; 10 cases diagnosed F45.2X hypochondriasis, unspecified; and one case diagnosed
30
31 with both F45.2 and F45.2X) and 122 valid cases of dysmorphophobia available for analyses.
32
33
34
35
36 The length of the received medical records ranged from one to about 1,000 pages.
37
38
39
40

41 **Chart review**

42
43
44 Two raters conducted an independent chart review of each medical record using a predefined
45
46 scoring sheet (**Supplementary material**). A diagnosis was established independently by each
47
48 of the two raters, based on all available information in the medical records. The raters for the
49
50 hypochondriasis files were four clinical psychologists and one psychiatrist, with three of these
51
52 five raters having a PhD degree. The raters of the dysmorphophobia files were six clinical
53
54 psychologists and one psychiatrist, three of whom had a PhD. All had extensive clinical
55
56 experience in the assessment and treatment of their respective disorders.
57
58
59
60

1
2
3 Upon revision of the chart, raters decided whether the ICD-10 definition of
4
5 hypochondriasis or dysmorphophobia was met. Since the ICD-10 contains a narrative
6
7 description of the disorder, rather than specific operational diagnostic criteria, raters were also
8
9 asked whether the case under evaluation met diagnostic criteria for the corresponding
10
11 diagnoses of hypochondriasis or body dysmorphic disorder according to the DSM-IV-TR and,
12
13 given the recent updates in the diagnostic criteria, also for the DSM-5 illness anxiety disorder
14
15 or body dysmorphic disorder. If the two independent raters disagreed regarding the presence
16
17 of a diagnosis, a third blind rater was asked to read the file. In a validation study, the expert
18
19 rater is considered to be the gold standard and the diagnostic code in the file is the test. Hence,
20
21 when a rater agreed with the diagnostic code in the file, the case was considered to be a ‘true
22
23 positive’, and when a rater considered that a case did not meet criteria for the disorder in
24
25 question, the case was defined as a ‘false positive.’ For false positive cases, the raters were
26
27 asked to provide the most likely alternative diagnosis, according to their clinical judgement.
28
29
30
31
32

33 Since the NPR only includes cases from specialist settings, raters also assessed
34
35 symptom severity and global functioning related to hypochondriasis or dysmorphophobia in
36
37 order to better evaluate the representativeness of the cases. These variables were assessed,
38
39 respectively, by means of the Clinical Global Impression – Severity (CGI-S)[21, 22] and the
40
41 Global Assessment of Functioning (GAF)[23] rating scales. The CGI-S is a one-item measure
42
43 assessing the severity of psychopathology from 1 to 7, where 1 is ‘normal’ and 7 is ‘among
44
45 the most extremely ill patients’[21]. The CGI-S has shown good internal consistency and
46
47 concurrent validity[24]. The GAF is also a one-item measure (ranging from 1 to 100) used in
48
49 psychiatry to assess the general social, occupational, and psychological functioning of
50
51 adults[25]. Scores in the 1-10 range indicate a severely impaired functioning with persistent
52
53 danger for self or others, whereas scores in the 91-100 range indicate superior functioning
54
55 with no symptoms. The GAF has shown good validity and reliability in the assessment of
56
57
58
59
60

1
2
3 global functioning in psychiatric patients[25]. Both the CGI-S and the GAF are generally
4 rated in reference to the time of the assessment. Because of the nature of this study, raters
5 were instead asked to make an estimation of the average severity and function of the patient
6 for the whole time covered in the file.
7
8
9
10
11
12
13
14

15 **Statistical analyses**

16
17 The rate of agreement between the two evaluators of each file was calculated. Since the
18 raters' responses in both hypochondriasis and dysmorphophobia cases were very imbalanced
19 (i.e., the answer 'yes' indicating presence of the disorder was much more common for all
20 raters, compared to 'no'), we did not use Kappa statistics to examine inter-rater reliability.
21 This was because in cases with this kind of imbalance in responses, Kappa results may be
22 misleading, showing a paradox where the coefficients are low despite high agreement
23 rates[26, 27]. Instead, we calculated the percent agreement between the two initial raters,
24 which is a valid alternative to Kappa coefficients when using well trained raters who are not
25 likely to guess[28]. The percent agreement is the percent of ratings where both raters made
26 the same judgement.
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41

42 Further, for each diagnosis, we calculated the positive predictive value (PPV) and
43 their corresponding 95% confidence intervals (CIs). The PPV is calculated by dividing the
44 cases diagnosed correctly by the sum of the true positives and the false positives.
45
46
47
48

49 To assess the inter-rater agreement for the CGI-S and the GAF scales, intraclass
50 correlation coefficients (ICC) with 95% CIs were calculated based on one-way mixed-effects
51 model for average measures, absolute agreement[29]. Stata, version 15.1 (StataCorp LLC)
52 was used for all the analyses.

Patient and public involvement

No patients were involved in setting the research question nor were they involved in developing plans for the study design or data analysis. There are no plans to directly disseminate the results of the research to study participants or the relevant patient community. The dissemination to the public will be achieved through media outreach (for example, press release and communication) upon publication of this study.

RESULTS

Validity and reliability of hypochondriasis codes in the National Patient Register

A total of 84 cases with a register diagnosis of hypochondriasis (45 females, 53.6%) were included in the analysis. The cases came mostly from psychiatric clinics ($n=75$, 89.3%), followed by emergency units ($n=3$, 3.6%), internal medicine clinics ($n=2$, 2.4%), neurology clinics ($n=2$, 2.4%), gynecology clinics ($n=1$, 1.2%), and oncology clinics ($n=1$, 1.2%).

In 80 (95.2%) of the 84 cases, the initial two raters agreed on the presence or absence of a hypochondriasis diagnosis in the file. A third independent rater reviewed the files of four cases where there was a disagreement between the two initial raters: two of these four files were considered true positives and another two were considered false positives.

In total, 67 (79.8%) of the 84 cases were defined as true positives. In the majority of cases ($n=63$, 94%), both raters considered that the criteria were met according to all three diagnostic systems (i.e., ICD-10, DSM-IV-TR, and DSM-5). In the remaining four cases, raters considered that the ICD-10 definition and the DSM-IV-TR diagnostic criteria were met, but not the DSM-5 criteria.

The 67 true positive cases translated into a PPV of 0.80 (95% CI, 0.70-0.88). For the remaining 17 false positive cases, the most frequent alternative diagnosis was

dysmorphophobia ($n=11$), followed by psychotic disorder ($n=4$), borderline personality disorder ($n=2$), major depressive disorder ($n=2$), somatization disorder ($n=2$), somatoform disorder, unspecified ($n=2$), and obsessive-compulsive disorder ($n=2$) (**Table 1**). Of note, eight of the nine cases from non-psychiatric clinics were considered to be true positives (i.e., correctly classified).

Validity and reliability of dysmorphophobia codes in the National Patient Register

A total of 122 cases with a register diagnosis of dysmorphophobia (83 females, 68.0%) were included in the analysis. The majority of files ($n=106$, 86.9%) came from psychiatric clinics, with the remaining coming from dermatology clinics ($n=11$, 9.0%), plastic surgery clinics ($n=4$, 3.3%), and one from a gynecological clinic ($n=1$, 0.8%).

There was agreement between the two initial raters regarding the presence or absence of a dysmorphophobia diagnosis in 113 of the 122 files (92.6%). Of the nine cases where there was a disagreement, the third independent rater concluded that two were true positives and seven false positives.

In total, 111 (91.0%) of the 122 cases were classed as true positives. In the vast majority of cases ($n=108$, 97.3%), the criteria were met according to all three diagnostic systems, according to both raters. In the three remaining cases, raters considered that the ICD-definition was met, but not all criteria according to the more stringent diagnostic systems, DSM-IV-TR and DSM-5.

Based on the 111 true positive cases, the PPV was 0.91 (95% CI, 0.84-0.95). For the remaining 11 cases defined as false positives, the most frequent alternative diagnoses were excoriation (skin-picking) disorder ($n=3$), factitial dermatitis ($n=3$), eating disorder ($n=3$), hypochondriasis ($n=2$), pervasive development disorder ($n=2$), and psychotic disorder ($n=2$)

1
2
3 (Table 1). Of note, the four cases from plastic surgery clinics were considered to be true
4
5 positives, as were seven of the eleven cases (63.6%) from dermatology clinics, while the one
6
7 case from a gynecological clinic was considered to be a false positive.
8
9

10 11 12 13 **Severity and global function**

14
15
16 CGI-S and the GAF data were available for 63 of the 67 true positive hypochondriasis cases;
17
18 in the remaining four cases, raters had not scored the scales due to lack of information in the
19
20 medical file, thus the information was missing. The mean score for the CGI-S was 4.49
21
22 (SD=1.01, median=5, interquartile range [IQR]=1) for rater 1 and 4.57 (SD=0.73, median=5,
23
24 IQR=1) for rater 2, indicating moderate to marked severity of the assessed cases (**Figure 2,**
25
26 **panel A**). The inter-rater reliability for the CGI-S was good (ICC=0.75 [95% CI, 0.59-0.85]).
27
28 The mean GAF score was 54.40 (SD=9.41, median=50, IQR=12) for rater 1 and 52.63
29
30 (SD=9.45, median=49, IQR=15) for rater 2, indicating moderate impairment of global
31
32 functioning (**Figure 2, panel A**). The inter-rater reliability for the GAF was also good
33
34 (ICC=0.81 [95% CI, 0.69-0.89]).
35
36
37
38
39

40
41 For dysmorphophobia, CGI-S and GAF scores were available for 94 of the 111 true
42
43 positive cases; in the remaining 17 cases, raters had not scored the scales due to lack of
44
45 information in the medical file. The mean score for the CGI-S was 4.70 (SD=1.20, median=4,
46
47 IQR=2) for rater 1 and 4.99 (SD=0.71, median=5, IQR=1) for rater 2, indicating moderate to
48
49 marked severity of the assessed cases (**Figure 2, panel B**). The inter-rater reliability for the
50
51 CGI-S was moderate (ICC=0.61 [95% CI, 0.41-0.74]). The mean GAF-score was 47.98
52
53 (SD=12.77, median=52.5, IQR=15) as assessed by rater 1 and 47.79 (SD=7.32, median=51,
54
55 IQR=8) as assessed by rater 2, indicating serious impairment in global functioning (**Figure 2,**
56
57 **panel B**). The inter-rater reliability for the GAF was moderate (ICC=0.65 [CI, 0.48-0.77]).
58
59
60

DISCUSSION

This study evaluated the validity and reliability of the diagnostic codes for hypochondriasis and dysmorphophobia in the Swedish NPR using a chart review design, which is considered to be the gold standard procedure for assessing diagnostic validity[3]. Our results showed that the diagnostic validity of both disorders is generally good, with a PPV of 0.80 for hypochondriasis and 0.91 for dysmorphophobia. These findings are in line with those of previous studies validating other psychiatric disorders in the NPR, including bipolar disorder (PPV=0.81-0.91)[4], schizophrenia (PPV=0.91-1.0)[8], obsessive-compulsive disorder (PPV=0.55-0.96)[3], chronic tic disorders (PPV=0.86-0.97)[3], and social anxiety disorder (PPV=0.72-0.88)[7]. Furthermore, the inter-rater agreement for both hypochondriasis and dysmorphophobia was satisfactory[30].

Nonetheless, 20% of the hypochondriasis files and almost 10% of the dysmorphophobia files were misclassified. For the majority of the misclassified hypochondriasis files (64.7%), dysmorphophobia was suggested as the most likely alternative diagnosis. Since both disorders share the same diagnostic code, it is probable that at least a proportion of those cases were a result of coding errors (i.e., the clinician not knowing that the F45.2A was the corresponding code for dysmorphophobia). In the same way, a smaller but non-negligible proportion of dysmorphophobia cases (18.2%) were judged to better correspond to a diagnosis of hypochondriasis. Thus, it seems that the high proximity and similarity of these adjacent codes poses a challenge for clinicians and may have implications for register-based studies. Because patients receive a new diagnostic code with every specialist visit, individuals in the registers often receive multiple diagnostic codes over time; in this context, it may be wise to question the validity of cases receiving both diagnoses during the follow-up. For this reason, we suggest that future register-based studies using the

1
2
3 ICD-10 diagnosis of hypochondriasis (F45.2) should exclude individuals with recorded

ICD-10 diagnosis of hypochondriasis (F45.2) should exclude individuals with recorded
dysmorphophobia codes (F45.2A) at any point during the follow-up, and *vice versa*, in order
to reduce the risk of potential misclassification to a minimum.

An additional issue in the register-based epidemiological studies conducted in
Sweden is that the NPR only includes diagnoses assigned by physicians in specialist care
settings. Therefore, it is often assumed that the patients in the registers are more severe and
less functional than the average patient. This may affect the generalizability of the results
from register-based studies to non-specialist clinical settings. Contrary to this assumption, the
hypochondriasis sample had a broad distribution of severity and global functioning scores,
with most patients being moderately ill and having a moderately impaired function. Regarding
the dysmorphophobia files, distributions of the severity and functioning variables were
somewhat skewed to the more severe end of the spectrum.

It is well known that individuals with hypochondriasis and dysmorphophobia are
often reluctant to seek mental health support due to embarrassment about symptoms, poor
insight, and a preference for non-psychiatric care (e.g., cosmetic procedures in
dysmorphophobia, somatic care in hypochondriasis)[31-34]. As a result, both conditions are
presumably severely underdiagnosed[10, 12]. It is therefore paramount to improve detection
and diagnosis of these conditions not only amongst mental health practitioners, but also across
a wide range of medical specialists (e.g., general practitioners, plastic surgeons,
dermatologists). Further, better collaboration between somatic and mental health services is
needed in order to improve the chances that these individuals will receive appropriate
evidence based treatments.

The main strengths of this study are the random selection of cases from all over
Sweden and the thorough review of the medical files by two or three independent expert
raters, showing good inter-rater agreement. However, there are also some limitations to

1
2
3 consider. First, the study had no control diagnostic group, which may result in an increased
4
5 risk of over-confirming the target diagnosis. Second, there is a risk for selection bias, given
6
7 that only 28% of the requested hypochondriasis files and 41% of the requested
8
9 dysmorphophobia files could be included in the final analyses. However, since the reasons for
10
11 not including the files were mostly practical (e.g., some clinics did no longer exist, had
12
13 confidentiality concerns or no personnel available to send the files), we assume that a
14
15 systematic bias is unlikely. Third, we were unable to evaluate the validity of the
16
17 hypochondriasis subtypes separately given the small number of files received containing these
18
19 specific codes (11 files containing only the codes F45.2C or F45.2X). Finally, since the raters
20
21 did not interview the patients in person, the scoring of CGI-S and the GAF should be seen as a
22
23 general clinical estimate of the patients' severity and general function, rather than a precise
24
25 assessment.

33

34 CONCLUSIONS

35
36 The ICD-10 codes for both hypochondriasis and dysmorphophobia in the Swedish NPR are
37
38 sufficiently valid and reliable for their use in register-based studies. However, the results of
39
40 such studies should be interpreted in the context of a possible over-representation of severe
41
42 and highly impaired cases in the register, particularly for dysmorphophobia.

TABLES AND FIGURES

Table 1. Alternative diagnoses for false positive cases of hypochondriasis ($n=17$) and dysmorphophobia ($n=11$).

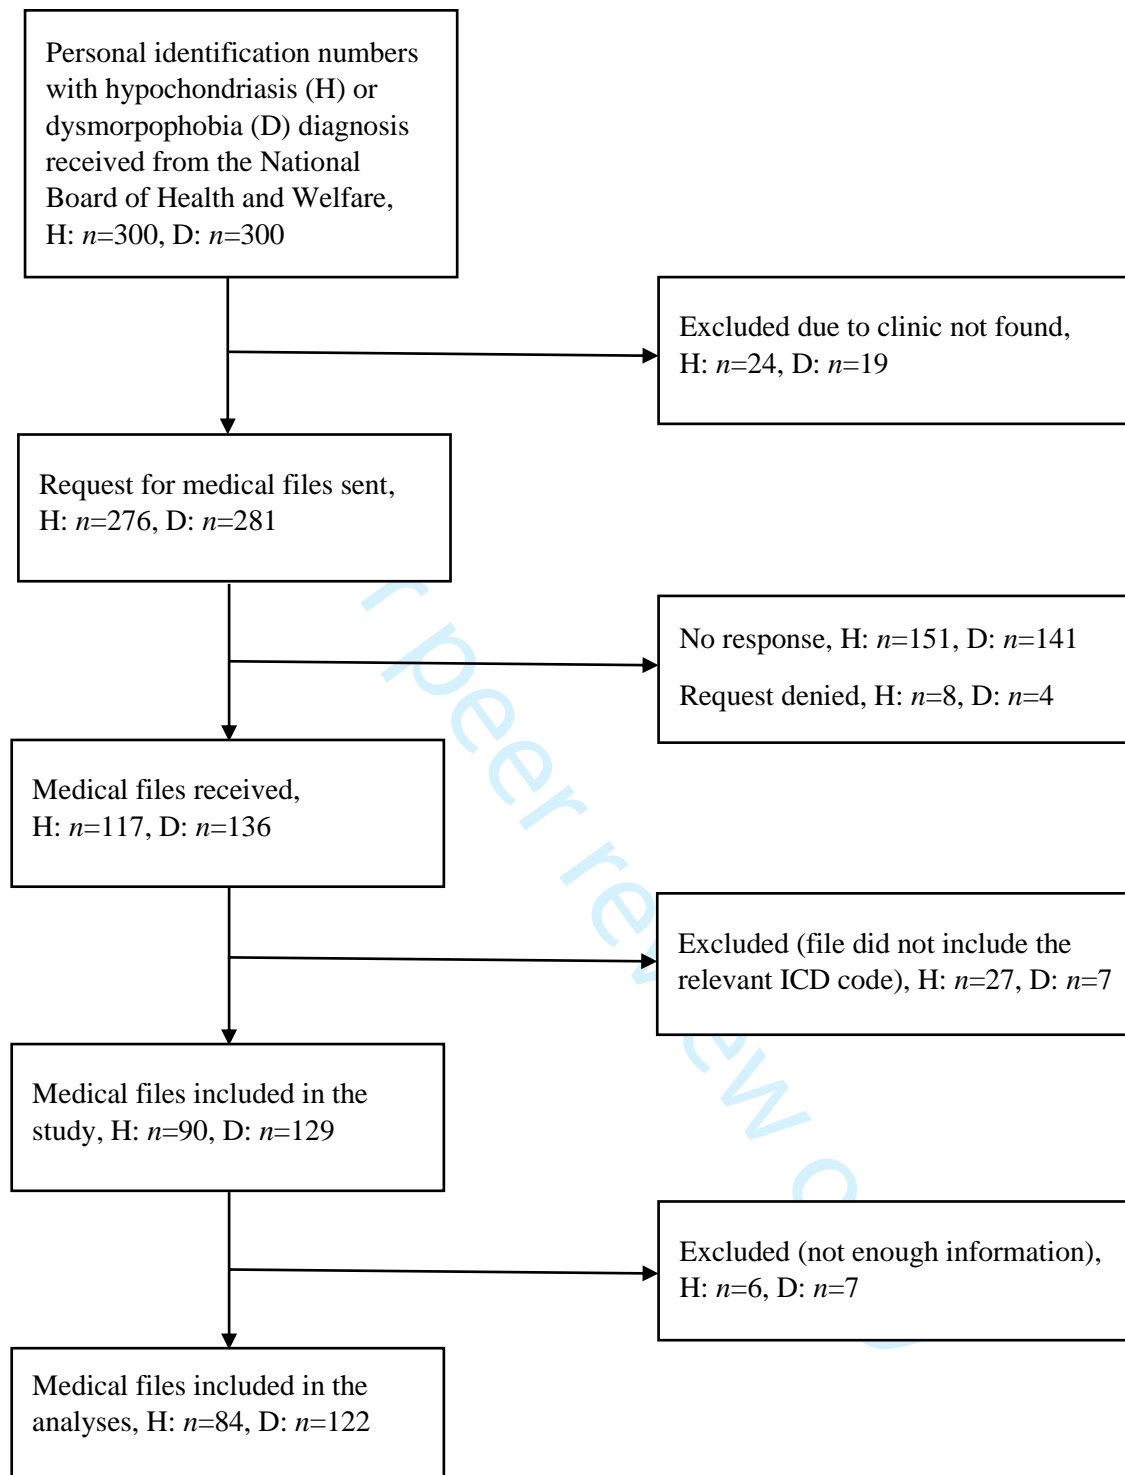

Hypochondriasis	<i>n</i>	Dysmorphophobia	<i>n</i>
Dysmorphophobia	11	Excoriation (skin-picking) disorder	3
Psychotic disorder	4	Factitial dermatitis	3
Somatization disorder	2	Eating disorder, unspecified	3
Somatoform disorder, unspecified	2	Hypochondriasis	2
Obsessive-compulsive disorder	2	Psychotic disorder	2
Major depressive disorder	2	Pervasive developmental disorder	2
Borderline personality disorder	2	Delusional disorder	1
General anxiety disorder	1	Somatization disorder	1
Anxiety disorder, unspecified	1	Obsessive-compulsive disorder	1
Bipolar disorder	1	Trichotillomania	1
Pervasive developmental disorder	1	Social phobia	1
Substance dependence disorder	1	Generalized anxiety disorder	1
Acute stress reaction	1	Post-traumatic stress disorder	1
		Gender identity disorder	1
		Borderline personality disorder	1

Note: Numbers do not add up to the total of false positive cases ($n=17$ for hypochondriasis and $n=11$ for dysmorphophobia) since, for multiple cases, raters suggested more than one alternative diagnosis.

Scoring sheet for the validation of Hypochondriasis and Dysmorphophobia codes

Rater: _____

Participant code: _____ Sex: Man / Woman

Clinic: Psychiatry / Non-psychiatric; specialty: _____

ICD-10 definition of F45.2 hypochondriacal disorder (which includes both hypochondriasis and dysmorphophobia)

Hypochondriacal disorder – The essential feature is a persistent preoccupation with the possibility of having one or more serious and progressive physical disorders. Patients manifest persistent somatic complaints or a persistent preoccupation with their physical appearance. Normal or commonplace sensations and appearances are often interpreted by patients as abnormal and distressing, and attention is usually focused upon only one or two organs or systems of the body. Marked depression and anxiety are often present, and may justify additional diagnoses.

Please tick in the right column the code that better describes the clinical presentation:

Hypochondria, if persistent somatic complaints	
Dysmorphophobia, if persistent preoccupation with their physical appearance	

DSM-IV-TR criteria for Hypochondriasis (tick those that apply on the right column)

A. Preoccupation with fears of having, or the idea that one has, a serious disease based on the person's misinterpretation of bodily symptoms.	
B. The preoccupation persists despite appropriate medical evaluation and reassurance.	
C. The belief in Criterion A is not of delusional intensity (as in Delusional Disorder, Somatic Type) and is not restricted to a circumscribed concern about appearance (as in Body Dysmorphic Disorder).	
D. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
E. The duration of the disturbance is at least 6 months.	
F. The preoccupation is not better accounted for by Generalized Anxiety Disorder, Obsessive-Compulsive Disorder, Panic Disorder, a Major Depressive Episode, Separation Anxiety, or another Somatoform Disorder.	

DSM-5 criteria for Illness Anxiety Disorder (tick those that apply on the right column)

A. Preoccupation with having or acquiring a serious illness.	
B. Somatic symptoms are not present or, if present, are only mild in intensity. If another medical condition is present or there is a high risk for developing a medical condition (e.g., strong family history is present), the preoccupation is clearly excessive or disproportionate.	

C. There is a high level of anxiety about health, and the individual is easily alarmed about personal health status.	
D. The individual performs excessive health-related behaviors (e.g., repeatedly checks his or her body for signs of illness) or exhibits maladaptive avoidance (e.g., avoids doctor appointments and hospitals).	
E. Illness preoccupation has been present for at least 6 months, but the specific illness that is feared may change over that period of time.	
F. The illness-related preoccupation is not better explained by another mental disorder, such as somatic symptom disorder, panic disorder, generalized anxiety disorder, body dysmorphic disorder, obsessive-compulsive disorder, or delusional disorder, somatic type.	

DSM-IV-TR criteria for Body Dysmorphic Disorder (tick those that apply on the right column)

A. Preoccupation with an imagined defect in appearance. If a slight physical anomaly is present, the person’s concern is markedly excessive.	
B. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
C. The preoccupation is not better accounted for by another mental disorder (e.g., dissatisfaction with body shape and size in anorexia nervosa).	

DSM-5 criteria for Body Dysmorphic Disorder (tick those that apply on the right column)

A. Preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others.	
B. At some point during the course of the disorder, the individual has performed repetitive behaviors (e.g., mirror checking, excessive grooming, skin picking, reassurance seeking) or mental acts (e.g., comparing his or her appearance with that of others) in response to the appearance concerns.	
C. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
D. The appearance preoccupation is not better explained by concerns with body fat or weight in an individual whose symptoms meet diagnostic criteria for an eating disorder.	

Assessment

Diagnosis. Please mark all the answers that apply.

ABSTRACT

Objectives: In the International Classification of Diseases, Tenth Edition (ICD-10), hypochondriasis (illness anxiety disorder) and dysmorphophobia (body dysmorphic disorder) share the same diagnostic code (F45.2). However, the Swedish ICD-10 allows for these disorders to be coded separately (F45.2 and F45.2A, respectively), potentially offering unique opportunities for register-based research on these conditions. We assessed the validity and reliability of their ICD-10 codes in the Swedish National Patient Register (NPR).

Design: Retrospective chart review.

Methods: Six hundred individuals with a diagnosis of hypochondriasis or dysmorphophobia (300 each) were randomly selected from the NPR. Their medical files were requested from the corresponding clinics, located anywhere in Sweden. Two independent raters assessed each file according to ICD-10 definitions and Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR) and Fifth Edition (DSM-5) criteria. Raters also completed the Clinical Global Impression–Severity (CGI-S) and the Global Assessment of Functioning (GAF).

Primary outcome measure: Percent between-rater agreement and positive predictive value (PPV). Intraclass correlation coefficients for the CGI-S and the GAF.

Results: Eighty-four hypochondriasis and 122 dysmorphophobia files were received and analyzed. The inter-rater agreement rate regarding the presence or absence of a diagnosis was 95.2% for hypochondriasis and 92.6% for dysmorphophobia. Sixty-seven hypochondriasis files (79.8%) and 111 dysmorphophobia files (91.0%) were considered ‘true positive’ cases (PPV=0.80 and PPV=0.91, respectively). CGI-S scores indicated that symptoms were moderately to markedly severe, while GAF scores suggested moderate impairment for

1
2
3 hypochondriasis and moderate to serious impairment for dysmorphophobia. CGI-S and GAF
4
5 inter-rater agreement was good for hypochondriasis and moderate for dysmorphophobia.
6
7

8 **Conclusions:** The Swedish ICD-10 codes for hypochondriasis and dysmorphophobia are
9
10 sufficiently valid and reliable for register-based studies. The results of such studies should be
11
12 interpreted in the context of a possible over-representation of severe and highly impaired
13
14 cases in the register, particularly for dysmorphophobia.

STRENGTHS AND LIMITATIONS OF THIS STUDY

- Randomly drawn sample of hypochondriasis and dysmorphophobia cases from all over Sweden.
- Thorough review of medical files by at least two independent expert raters.
- Good inter-rater reliability.
- No control diagnostic group.
- Limited number of cases and potential risk of selection bias.

INTRODUCTION

The National Board of Health and Welfare is a Swedish governmental agency that in 1964 established the National Patient Register (NPR), a health register with individual-level reporting of clinical diagnoses which plays a crucial role in Swedish register-based epidemiological research[1]. The quality of the research conducted on NPR data is highly dependent on the diagnostic validity of the diagnostic codes[2]. Diagnoses in the NPR are coded according to the Swedish International Classification of Diseases (ICD) system, which was adapted from the World Health Organization ICD classification system[1]. The validity of a wide range of ICD diagnostic codes in the Swedish NPR differs between diagnoses, but is generally high[1]. Several diagnostic codes for psychiatric disorders have been examined and generally shown to be sufficiently valid and reliable for research purposes[3-8].

Hypochondriasis (also known as illness anxiety disorder) and dysmorphophobia (also known as body dysmorphic disorder) are two chronic and often severe psychiatric disorders associated with significant suffering and a high level of functional impairment[9]. Their estimated prevalence is 1-2% for hypochondriasis[10] and around 2% for dysmorphophobia[11, 12]. In the international version of the ICD-10[13], hypochondriasis and dysmorphophobia are classed as somatoform disorders and share the same diagnostic code (F45.2). It is therefore not possible to separate the two disorders for clinical or research purposes[13]. By contrast, the Swedish version of the ICD-10 includes an additional code that allows clinicians to separately diagnose these two disorders. Specifically, hypochondriasis is coded F45.2, whereas dysmorphophobia is coded F45.2A[14]. This distinction is in line with the most recent classification of these disorders in the ICD-11, which considers them as two separate, but closely related diagnoses within the obsessive-compulsive spectrum[9, 15-18]. Similarly, in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), hypochondriasis (illness anxiety disorder) and dysmorphophobia (body dysmorphic

1
2
3 disorder) are two different disorders, although they appear under separate chapters
4
5 (somatoform and obsessive-compulsive and related disorders, respectively)[9, 19, 20]. Thus,
6
7 the Swedish “anomaly” in the ICD-10 potentially offers a unique opportunity for register-
8
9 based studies on these disabling psychiatric conditions. However, the validity and reliability
10
11 of these diagnostic codes has not yet been established.
12
13
14

15 This study employed a chart review methodology to establish the validity of the
16
17 Swedish ICD-10 codes for hypochondriasis and dysmorphophobia in the NPR with the aim to
18
19 assess whether these codes are suitable for future register-based studies.
20
21
22
23
24

25 **METHODS**

26 **Procedures**

27
28
29 After receiving approval from the regional ethical review board in Stockholm (2016/2399-
30
31 31/5 and 2017/325-32), we requested 600 randomly selected personal identification numbers
32
33 of individuals who ever received a diagnosis of either hypochondriasis ($n=300$) or
34
35 dysmorphophobia ($n=300$) from the Swedish National Board of Health and Welfare. In
36
37 accordance with the protocol approved by the ethical review board, individual patients were
38
39 not asked for consent, as this would introduce selection biases. No weighting or other
40
41 adjustments were done to randomly select the cases.
42
43
44
45
46
47

48 For hypochondriasis, we requested 300 files with the ICD-10 code F45.2 and all its
49
50 subcodes (except for F45.2A), namely: F45.2B for nosophobia, F45.2C for cancer phobia,
51
52 F45.2D for venerophobia, and F45.2X for hypochondriasis, unspecified. For
53
54 dysmorphophobia, we requested 300 files with the ICD-10 code F45.2A. The dates of
55
56 registered diagnosis spanned from 1998 to 2016 for those with diagnoses assigned in inpatient
57
58 clinics, and from 2001 to 2016 for those with diagnoses assigned in outpatient clinics. To be
59
60

1
2
3 eligible for inclusion, a single ICD-10 diagnosis of hypochondriasis or dysmorphophobia at
4
5 any time during this time period was sufficient, regardless of whether the diagnosis was
6
7 primary or secondary or whether other comorbidities were present.
8
9

10
11 Following the procedures previously used in other validation studies by the research
12
13 group[3, 7], once the random cases had been identified, we sent written requests to the
14
15 corresponding archives or clinics, based on the hospital and medical specialty codes
16
17 associated to the cases. Cases were excluded when we could not find the associated clinic
18
19 (e.g., the clinic was no longer operative), when the clinic did not reply or declined
20
21 participation, when the diagnostic code under study was not documented in the received file
22
23 or when there was not enough information in the received file to make a diagnostic judgement
24
25 (e.g., a description of clinical symptoms was not available). **Figure 1** shows the flow for the
26
27 inclusion of cases for each diagnosis. In total, we received 84 valid cases of hypochondriasis
28
29 (including 72 cases diagnosed F45.2, hypochondriasis; one case diagnosed F45.2C, cancer
30
31 phobia; 10 cases diagnosed F45.2X hypochondriasis, unspecified; and one case diagnosed
32
33 with both F45.2 and F45.2X) and 122 valid cases of dysmorphophobia available for analyses.
34
35 The length of the received medical records ranged from one to about 1,000 pages.
36
37
38
39
40
41
42
43

44 **Chart review**

45
46 Two raters conducted an independent chart review of each medical record using a predefined
47
48 scoring sheet (**Supplementary material**). A diagnosis was established independently by each
49
50 of the two raters, based on all available information in the medical records. The raters for the
51
52 hypochondriasis files were four clinical psychologists and one psychiatrist, with three of these
53
54 five raters having a PhD degree. The raters of the dysmorphophobia files were six clinical
55
56 psychologists and one psychiatrist, three of whom had a PhD. All had extensive clinical
57
58 experience in the assessment and treatment of their respective disorders.
59
60

1
2
3 Upon revision of the chart, raters decided whether the ICD-10 definition of
4
5 hypochondriasis or dysmorphophobia was met. Since the ICD-10 contains a narrative
6
7 description of the disorder, rather than specific operational diagnostic criteria, raters were also
8
9 asked whether the case under evaluation met diagnostic criteria for the corresponding
10
11 diagnoses of hypochondriasis or body dysmorphic disorder according to the DSM-IV-TR and,
12
13 given the recent updates in the diagnostic criteria, also for the DSM-5 illness anxiety disorder
14
15 or body dysmorphic disorder. If the two independent raters disagreed regarding the presence
16
17 of a diagnosis, a third blind rater was asked to read the file. In a validation study, the expert
18
19 rater is considered to be the gold standard and the diagnostic code in the file is the test. Hence,
20
21 when a rater agreed with the diagnostic code in the file, the case was considered to be a ‘true
22
23 positive’, and when a rater considered that a case did not meet criteria for the disorder in
24
25 question, the case was defined as a ‘false positive.’ For false positive cases, the raters were
26
27 asked to provide the most likely alternative diagnosis, according to their clinical judgement.
28
29
30
31
32

33 Since the NPR only includes cases from specialist settings, raters also assessed
34
35 symptom severity and global functioning related to hypochondriasis or dysmorphophobia in
36
37 order to better evaluate the representativeness of the cases. These variables were assessed,
38
39 respectively, by means of the Clinical Global Impression – Severity (CGI-S)[21, 22] and the
40
41 Global Assessment of Functioning (GAF)[23] rating scales. The CGI-S is a one-item measure
42
43 assessing the severity of psychopathology from 1 to 7, where 1 is ‘normal’ and 7 is ‘among
44
45 the most extremely ill patients’[21]. The CGI-S has shown good internal consistency and
46
47 concurrent validity[24]. The GAF is also a one-item measure (ranging from 1 to 100) used in
48
49 psychiatry to assess the general social, occupational, and psychological functioning of
50
51 adults[25]. Scores in the 1-10 range indicate a severely impaired functioning with persistent
52
53 danger for self or others, whereas scores in the 91-100 range indicate superior functioning
54
55 with no symptoms. The GAF has shown good validity and reliability in the assessment of
56
57
58
59
60

1
2
3 global functioning in psychiatric patients[25]. Both the CGI-S and the GAF are generally
4 rated in reference to the time of the assessment. Because of the nature of this study, raters
5 were instead asked to make an estimation of the average severity and function of the patient
6 for the whole time covered in the file.
7
8
9
10
11
12
13
14

15 **Statistical analyses**

16
17 The rate of agreement between the two evaluators of each file was calculated. Since the
18 raters' responses in both hypochondriasis and dysmorphophobia cases were very imbalanced
19 (i.e., the answer 'yes' indicating presence of the disorder was much more common for all
20 raters, compared to 'no'), we did not use Kappa statistics to examine inter-rater reliability.
21 This was because in cases with this kind of imbalance in responses, Kappa results may be
22 misleading, showing a paradox where the coefficients are low despite high agreement
23 rates[26, 27]. Instead, we calculated the percent agreement between the two initial raters,
24 which is a valid alternative to Kappa coefficients when using well trained raters who are not
25 likely to guess[28]. The percent agreement is the percent of ratings where both raters made
26 the same judgement.
27

29
30
31
32
33
34
35
36
37
38
39
40
41

42 Further, for each diagnosis, we calculated the positive predictive value (PPV) and
43 their corresponding 95% confidence intervals (CIs). The PPV is calculated by dividing the
44 cases diagnosed correctly by the sum of the true positives and the false positives.
45
46
47
48

49 To assess the inter-rater agreement for the CGI-S and the GAF scales, intraclass
50 correlation coefficients (ICC) with 95% CIs were calculated based on one-way mixed-effects
51 model for average measures, absolute agreement[29]. Stata, version 15.1 (StataCorp LLC)
52 was used for all the analyses.

Patient and public involvement

No patients were involved in setting the research question nor were they involved in developing plans for the study design or data analysis. There are no plans to directly disseminate the results of the research to study participants or the relevant patient community. The dissemination to the public will be achieved through media outreach (for example, press release and communication) upon publication of this study.

RESULTS

Validity and reliability of hypochondriasis codes in the National Patient Register

A total of 84 cases with a register diagnosis of hypochondriasis (45 females, 53.6%) were included in the analysis. The cases came mostly from psychiatric clinics ($n=75$, 89.3%), followed by emergency units ($n=3$, 3.6%), internal medicine clinics ($n=2$, 2.4%), neurology clinics ($n=2$, 2.4%), gynecology clinics ($n=1$, 1.2%), and oncology clinics ($n=1$, 1.2%).

In 80 (95.2%) of the 84 cases, the initial two raters agreed on the presence or absence of a hypochondriasis diagnosis in the file. A third independent rater reviewed the files of four cases where there was a disagreement between the two initial raters: two of these four files were considered true positives and another two were considered false positives.

In total, 67 (79.8%) of the 84 cases were defined as true positives. In the majority of cases ($n=63$, 94%), both raters considered that the criteria were met according to all three diagnostic systems (i.e., ICD-10, DSM-IV-TR, and DSM-5). In the remaining four cases, raters considered that the ICD-10 definition and the DSM-IV-TR diagnostic criteria were met, but not the DSM-5 criteria.

The 67 true positive cases translated into a PPV of 0.80 (95% CI, 0.70-0.88). For the remaining 17 false positive cases, the most frequent alternative diagnosis was

dysmorphophobia ($n=11$), followed by psychotic disorder ($n=4$), borderline personality disorder ($n=2$), major depressive disorder ($n=2$), somatization disorder ($n=2$), somatoform disorder, unspecified ($n=2$), and obsessive-compulsive disorder ($n=2$) (**Table 1**). Of note, eight of the nine cases from non-psychiatric clinics were considered to be true positives (i.e., correctly classified).

Validity and reliability of dysmorphophobia codes in the National Patient Register

A total of 122 cases with a register diagnosis of dysmorphophobia (83 females, 68.0%) were included in the analysis. The majority of files ($n=106$, 86.9%) came from psychiatric clinics, with the remaining coming from dermatology clinics ($n=11$, 9.0%), plastic surgery clinics ($n=4$, 3.3%), and one from a gynecological clinic ($n=1$, 0.8%).

There was agreement between the two initial raters regarding the presence or absence of a dysmorphophobia diagnosis in 113 of the 122 files (92.6%). Of the nine cases where there was a disagreement, the third independent rater concluded that two were true positives and seven false positives.

In total, 111 (91.0%) of the 122 cases were classed as true positives. In the vast majority of cases ($n=108$, 97.3%), the criteria were met according to all three diagnostic systems, according to both raters. In the three remaining cases, raters considered that the ICD-definition was met, but not all criteria according to the more stringent diagnostic systems, DSM-IV-TR and DSM-5.

Based on the 111 true positive cases, the PPV was 0.91 (95% CI, 0.84-0.95). For the remaining 11 cases defined as false positives, the most frequent alternative diagnoses were excoriation (skin-picking) disorder ($n=3$), factitial dermatitis ($n=3$), eating disorder ($n=3$), hypochondriasis ($n=2$), pervasive development disorder ($n=2$), and psychotic disorder ($n=2$)

1
2
3 (Table 1). Of note, the four cases from plastic surgery clinics were considered to be true
4
5 positives, as were seven of the eleven cases (63.6%) from dermatology clinics, while the one
6
7 case from a gynecological clinic was considered to be a false positive.
8
9

10 11 12 13 **Severity and global function**

14
15
16 CGI-S and the GAF data were available for 63 of the 67 true positive hypochondriasis cases;
17
18 in the remaining four cases, raters had not scored the scales due to lack of information in the
19
20 medical file, thus the information was missing. The mean score for the CGI-S was 4.49
21
22 (SD=1.01, median=5, interquartile range [IQR]=1) for rater 1 and 4.57 (SD=0.73, median=5,
23
24 IQR=1) for rater 2, indicating moderate to marked severity of the assessed cases (**Figure 2,**
25
26 **panel A**). The inter-rater reliability for the CGI-S was good (ICC=0.75 [95% CI, 0.59-0.85]).
27
28 The mean GAF score was 54.40 (SD=9.41, median=50, IQR=12) for rater 1 and 52.63
29
30 (SD=9.45, median=49, IQR=15) for rater 2, indicating moderate impairment of global
31
32 functioning (**Figure 2, panel A**). The inter-rater reliability for the GAF was also good
33
34 (ICC=0.81 [95% CI, 0.69-0.89]).
35
36
37
38
39

40 For dysmorphophobia, CGI-S and GAF scores were available for 94 of the 111 true
41
42 positive cases; in the remaining 17 cases, raters had not scored the scales due to lack of
43
44 information in the medical file. The mean score for the CGI-S was 4.70 (SD=1.20, median=4,
45
46 IQR=2) for rater 1 and 4.99 (SD=0.71, median=5, IQR=1) for rater 2, indicating moderate to
47
48 marked severity of the assessed cases (**Figure 2, panel B**). The inter-rater reliability for the
49
50 CGI-S was moderate (ICC=0.61 [95% CI, 0.41-0.74]). The mean GAF-score was 47.98
51
52 (SD=12.77, median=52.5, IQR=15) as assessed by rater 1 and 47.79 (SD=7.32, median=51,
53
54 IQR=8) as assessed by rater 2, indicating serious impairment in global functioning (**Figure 2,**
55
56 **panel B**). The inter-rater reliability for the GAF was moderate (ICC=0.65 [CI, 0.48-0.77]).

DISCUSSION

This study evaluated the validity and reliability of the diagnostic codes for hypochondriasis and dysmorphophobia in the Swedish NPR using a chart review design, which is considered to be the gold standard procedure for assessing diagnostic validity[3]. Our results showed that the diagnostic validity of both disorders is generally good, with a PPV of 0.80 for hypochondriasis and 0.91 for dysmorphophobia. These findings are in line with those of previous studies validating other psychiatric disorders in the NPR, including bipolar disorder (PPV=0.81-0.91)[4], schizophrenia (PPV=0.91-1.0)[8], obsessive-compulsive disorder (PPV=0.55-0.96)[3], chronic tic disorders (PPV=0.86-0.97)[3], and social anxiety disorder (PPV=0.72-0.88)[7]. Furthermore, the inter-rater agreement for both hypochondriasis and dysmorphophobia was satisfactory[30].

Nonetheless, 20% of the hypochondriasis files and almost 10% of the dysmorphophobia files were misclassified. For the majority of the misclassified hypochondriasis files (64.7%), dysmorphophobia was suggested as the most likely alternative diagnosis. Since both disorders share the same diagnostic code, it is probable that at least a proportion of those cases were a result of coding errors (i.e., the clinician not knowing that the F45.2A was the corresponding code for dysmorphophobia). In the same way, a smaller but non-negligible proportion of dysmorphophobia cases (18.2%) were judged to better correspond to a diagnosis of hypochondriasis. Thus, it seems that the high proximity and similarity of these adjacent codes poses a challenge for clinicians and may have implications for register-based studies. Because patients receive a new diagnostic code with every specialist visit, individuals in the registers often receive multiple diagnostic codes over time; in this context, it may be wise to question the validity of cases receiving both diagnoses during the follow-up. For this reason, we suggest that future register-based studies using the

1
2
3 ICD-10 diagnosis of hypochondriasis (F45.2) should exclude individuals with recorded

ICD-10 diagnosis of hypochondriasis (F45.2) should exclude individuals with recorded
dysmorphophobia codes (F45.2A) at any point during the follow-up, and *vice versa*, in order
to reduce the risk of potential misclassification to a minimum.

An additional issue in the register-based epidemiological studies conducted in
Sweden is that the NPR only includes diagnoses assigned by physicians in specialist care
settings. Further, it is well known that individuals with hypochondriasis and
dysmorphophobia are often reluctant to seek mental health support due to embarrassment
about symptoms, poor insight, and a preference for non-psychiatric care (e.g., cosmetic
procedures in dysmorphophobia, somatic care in hypochondriasis)[31-34]. As a result, both
conditions are presumably severely underdiagnosed[10, 12] and it could be assumed that the
patients in the registers are more severe and less functional than the average patient. This may
affect the generalizability of the results from register-based studies to non-specialist clinical
settings. Nonetheless, the hypochondriasis sample had a broad distribution of severity and
global functioning scores, with most patients being moderately ill and having a moderately
impaired function. Regarding the dysmorphophobia files, distributions of the severity and
functioning variables were somewhat skewed to the more severe end of the spectrum.

The main strengths of this study are the random selection of cases from all over
Sweden and the thorough review of the medical files by two or three independent expert
raters, showing good inter-rater agreement. However, there are also some limitations to
consider. First, the study had no control diagnostic group, which may result in an increased
risk of over-confirming the target diagnosis. Second, there is a risk for selection bias, given
that only 28% of the requested hypochondriasis files and 41% of the requested
dysmorphophobia files could be included in the final analyses. However, since the reasons for
not including the files were mostly practical (e.g., some clinics did no longer exist, had

1
2
3 confidentiality concerns or no personnel available to send the files), we assume that a
4
5 systematic bias is unlikely. Third, we were unable to evaluate the validity of the
6
7 hypochondriasis subtypes separately given the small number of files received containing these
8
9 specific codes (11 files containing only the codes F45.2C or F45.2X). Finally, since the raters
10
11 did not interview the patients in person, the scoring of CGI-S and the GAF should be seen as a
12
13 general clinical estimate of the patients' severity and general function, rather than a precise
14
15 assessment.
16
17
18
19
20
21

22 CONCLUSIONS

23
24
25 The ICD-10 codes for both hypochondriasis and dysmorphophobia in the Swedish NPR are
26
27 sufficiently valid and reliable for their use in register-based studies. However, the results of
28
29 such studies should be interpreted in the context of a possible over-representation of severe
30
31 and highly impaired cases in the register, particularly for dysmorphophobia.

15

16 **Contributorship statement:** LFC, DMC, ES, CR, and JH were involved in the conception of
17 the research question and designed the study protocol. AVP and SK were the data managers
18 and administrators for the project. DR, MG, VZI, JL, SÖ, OF, JI, and KI were independent
19 raters in the chart review. DR contributed to the data management and performed the
20 statistical analyses. DR and LFC drafted the manuscript. LFC and DMC provided supervision.
21 All authors contributed to the final version of the manuscript by providing substantial
22 intellectual contributions. The authors read and approved the final manuscript.

TABLES AND FIGURES

Table 1. Alternative diagnoses for false positive cases of hypochondriasis ($n=17$) and dysmorphophobia ($n=11$).

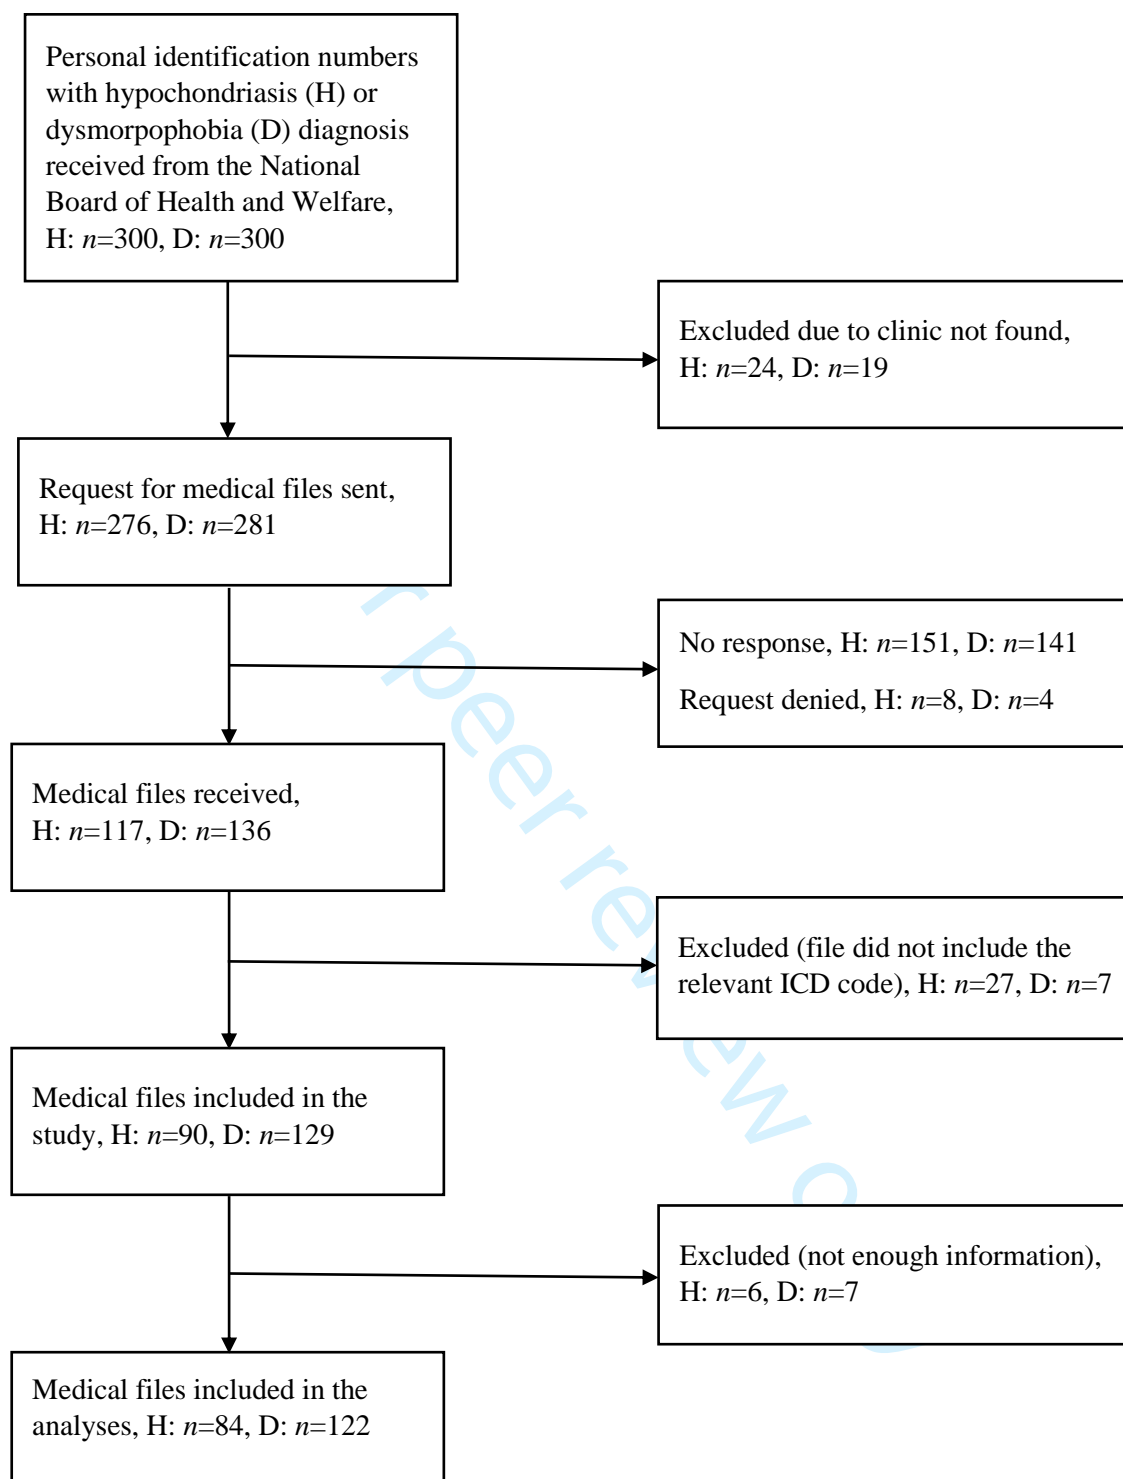

Hypochondriasis	<i>n</i>	Dysmorphophobia	<i>n</i>
Dysmorphophobia	11	Excoriation (skin-picking) disorder	3
Psychotic disorder	4	Factitial dermatitis	3
Somatization disorder	2	Eating disorder, unspecified	3
Somatoform disorder, unspecified	2	Hypochondriasis	2
Obsessive-compulsive disorder	2	Psychotic disorder	2
Major depressive disorder	2	Pervasive developmental disorder	2
Borderline personality disorder	2	Delusional disorder	1
General anxiety disorder	1	Somatization disorder	1
Anxiety disorder, unspecified	1	Obsessive-compulsive disorder	1
Bipolar disorder	1	Trichotillomania	1
Pervasive developmental disorder	1	Social phobia	1
Substance dependence disorder	1	Generalized anxiety disorder	1
Acute stress reaction	1	Post-traumatic stress disorder	1
		Gender identity disorder	1
		Borderline personality disorder	1

Note: Numbers do not add up to the total of false positive cases ($n=17$ for hypochondriasis and $n=11$ for dysmorphophobia) since, for multiple cases, raters suggested more than one alternative diagnosis.

Scoring sheet for the validation of Hypochondriasis and Dysmorphophobia codes

Rater: _____

Participant code: _____ Sex: Man / Woman

Clinic: Psychiatry / Non-psychiatric; specialty: _____

ICD-10 definition of F45.2 hypochondriacal disorder (which includes both hypochondriasis and dysmorphophobia)

Hypochondriacal disorder – The essential feature is a persistent preoccupation with the possibility of having one or more serious and progressive physical disorders. Patients manifest persistent somatic complaints or a persistent preoccupation with their physical appearance. Normal or commonplace sensations and appearances are often interpreted by patients as abnormal and distressing, and attention is usually focused upon only one or two organs or systems of the body. Marked depression and anxiety are often present, and may justify additional diagnoses.

Please tick in the right column the code that better describes the clinical presentation:

Hypochondria, if persistent somatic complaints	
Dysmorphophobia, if persistent preoccupation with their physical appearance	

DSM-IV-TR criteria for Hypochondriasis (tick those that apply on the right column)

A. Preoccupation with fears of having, or the idea that one has, a serious disease based on the person's misinterpretation of bodily symptoms.	
B. The preoccupation persists despite appropriate medical evaluation and reassurance.	
C. The belief in Criterion A is not of delusional intensity (as in Delusional Disorder, Somatic Type) and is not restricted to a circumscribed concern about appearance (as in Body Dysmorphic Disorder).	
D. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
E. The duration of the disturbance is at least 6 months.	
F. The preoccupation is not better accounted for by Generalized Anxiety Disorder, Obsessive-Compulsive Disorder, Panic Disorder, a Major Depressive Episode, Separation Anxiety, or another Somatoform Disorder.	

DSM-5 criteria for Illness Anxiety Disorder (tick those that apply on the right column)

A. Preoccupation with having or acquiring a serious illness.	
B. Somatic symptoms are not present or, if present, are only mild in intensity. If another medical condition is present or there is a high risk for developing a medical condition (e.g., strong family history is present), the preoccupation is clearly excessive or disproportionate.	

C. There is a high level of anxiety about health, and the individual is easily alarmed about personal health status.	
D. The individual performs excessive health-related behaviors (e.g., repeatedly checks his or her body for signs of illness) or exhibits maladaptive avoidance (e.g., avoids doctor appointments and hospitals).	
E. Illness preoccupation has been present for at least 6 months, but the specific illness that is feared may change over that period of time.	
F. The illness-related preoccupation is not better explained by another mental disorder, such as somatic symptom disorder, panic disorder, generalized anxiety disorder, body dysmorphic disorder, obsessive-compulsive disorder, or delusional disorder, somatic type.	

DSM-IV-TR criteria for Body Dysmorphic Disorder (tick those that apply on the right column)

A. Preoccupation with an imagined defect in appearance. If a slight physical anomaly is present, the person's concern is markedly excessive.	
B. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
C. The preoccupation is not better accounted for by another mental disorder (e.g., dissatisfaction with body shape and size in anorexia nervosa).	

DSM-5 criteria for Body Dysmorphic Disorder (tick those that apply on the right column)

A. Preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others.	
B. At some point during the course of the disorder, the individual has performed repetitive behaviors (e.g., mirror checking, excessive grooming, skin picking, reassurance seeking) or mental acts (e.g., comparing his or her appearance with that of others) in response to the appearance concerns.	
C. The preoccupation causes clinically significant distress or impairment in social, occupational, or other important areas of functioning.	
D. The appearance preoccupation is not better explained by concerns with body fat or weight in an individual whose symptoms meet diagnostic criteria for an eating disorder.	

Assessment

Diagnosis. Please mark all the answers that apply.

Hypochondria	Body Dysmorphic Disorder
<input type="radio"/> Diagnostic criteria are clearly met, <u>according to the ICD-10 definition</u>	<input type="radio"/> Diagnostic criteria are clearly met, <u>according to the ICD-10 definition</u>
<input type="radio"/> Diagnostic criteria are clearly met, <u>according to DSM-IV-TR criteria</u>	<input type="radio"/> Diagnostic criteria are clearly met, <u>according to DSM-IV-TR criteria</u>
<input type="radio"/> Diagnostic criteria are clearly met, <u>according to DSM-5 criteria</u>	<input type="radio"/> Diagnostic criteria are clearly met, <u>according to DSM-5 criteria</u>
<input type="radio"/> Probable, <u>according to the ICD-10 definition</u>	<input type="radio"/> Probable, <u>according to the ICD-10 definition</u>
<input type="radio"/> Probable, <u>according to DSM-IV-TR criteria</u>	<input type="radio"/> Probable, <u>according to DSM-IV-TR criteria</u>
<input type="radio"/> Probable, <u>according to DSM-5 criteria</u>	<input type="radio"/> Probable, <u>according to DSM-5 criteria</u>

Neither ICD-10 nor DSM-IV criteria for **Hypochondria** nor **Body Dysmorphic Disorder** are met

Insufficient information to make a decision about either **Hypochondria** or **Body Dysmorphic Disorder** diagnosis because there is no or very minimal description of psychiatric symptoms in the file (e.g., the file comes from a non-psychiatric clinic with no description of psychiatric symptoms, only blood tests available, etc.)

If neither Hypochondria nor Body Dysmorphic Disorder are present, please state the most likely alternative:

Clinical Global Impression – Severity (CGI-S). Considering your total clinical experience with this particular population, how mentally ill is the patient? (refer to the hypochondria or body dysmorphic symptoms only; if they are not present, leave this question blank)

0. Cannot be assessed (insufficient information)
1. Normal, not at all ill
2. Borderline mentally ill
3. Mildly ill
4. Moderately ill
5. Markedly ill
6. Severely ill
7. Among the most extremely ill patients

Global Assessment of Functioning (GAF) Scale. Consider psychological, social, and occupational functioning on a hypothetical continuum of mental health-illness. Do not include impairment in functioning due to physical (or environmental) limitations.

Please write your score from 0 to 100 (*consult the attached GAF scale for reference*)

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No.	Recommendation	Reported on Page Number/Line Number	Reported on Section/Paragraph
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Page 1, line 19 / Page 2, line 21	Title page / Abstract
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Page 2, line 23- 58- Page 3, line 3-6	Abstract
Introduction				
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Page 4, line 29- 60- Page 5, line 3-13	Introduction, Paragraph 2
Objectives	3	State specific objectives, including any prespecified hypotheses	Page 5, line 15- 20	Introduction, Paragraph 3
Methods				
Study design	4	Present key elements of study design early in the paper	Page 6, line 44- 49	Methods, Paragraph 4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Page 5, line 31- 60- Page 6, line 3-6	Methods, Paragraph 1-2
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	Page 5, line 31- 60- Page 6, line 3-25	Methods, Paragraph 1-3
		(b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed	Not applicable to our paper	Not applicable to our paper

		<i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case		
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Page 5, line 47-60 + Page 6, line 3-6 + Page 7, line 33-59 + Page 8, line 3-11	Methods, Paragraph 2, 6
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Page 6, line 44-59 + Page 7, line 3-59 + Page 8, line 3-11	Methods, Paragraph 4-6
Bias	9	Describe any efforts to address potential sources of bias	Page 5, line 38-45	Methods, Paragraph 1
Study size	10	Explain how the study size was arrived at	Page 6, line 8-11	Methods, Paragraph 3

Continued on next page

Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Page 8, line 1857	Methods, Paragraph 7-9
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Page 8, line 1857	Methods, Paragraph 7-9
		(b) Describe any methods used to examine subgroups and interactions	Not applicable	Not applicable
		(c) Explain how missing data were addressed	Not applicable	Not applicable
		(d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	Not applicable as this was a retrospective chart review	Not applicable as this was a retrospective chart review
		(e) Describe any sensitivity analyses	-	-
Results				
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	Page 20, line 319	Figure 1
		(b) Give reasons for non-participation at each stage	Page 20, line 319	Figure 1
		(c) Consider use of a flow diagram	Page 20, line 319	Figure 1
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Page 9, line 2634 + Page 10, line 2119	Results, Paragraph 1, 5
		(b) Indicate number of participants with missing data for each variable of interest	Page 11, line 1659	Results, Paragraph 9-10
		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	Not applicable	Not applicable
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time	Not applicable	Not applicable

bmjopen-2021-05857
 Downloaded from <http://bmjopen.bmj.com/> on April 19, 2024 by guest. Protected by copyright.

		<i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure	Not applicable	Not applicable
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	Not applicable	Not applicable
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Page 9, line 36-60 + Page 10, line 3-11, 30-60 + Page 11, line 3-59	Results, Paragraph 2-4, 6-10
		(b) Report category boundaries when continuous variables were categorized	-	-
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	-	-

Continued on next page

Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	-	-
Discussion				
Key results	18	Summarise key results with reference to study objectives	Page 13, line 9-16	Discussion, Paragraph 1
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Page 14, line 3-20	Discussion, Paragraph 5
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Page 12, line 13-16 + Page 13, line 3-10	Discussion, Paragraph 1-2
Generalisability	21	Discuss the generalisability (external validity) of the study results	Page 13, line 10-30	Discussion, Paragraph 3
Other information				
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Page 14, line 52-57	Below Conclusions

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
