Epidemiology of chronic pain in children and adolescents: a protocol for a systematic review update

Perri R Tutelman, Charlotte L Langley, Christine T Chambers, Jennifer A Parker, G Allen Finley, Darlene Chapman, Gareth T Jones, Gary J Macfarlane, Justina Marianayagam

ABSTRACT

Introduction Chronic pain, defined as persistent or recurring pain or pain lasting longer than 3 months, is a common childhood problem and can profoundly impact children's physical, psychological and social functioning. The last comprehensive systematic review estimating the prevalence of chronic pain in children and adolescents was published in 2011. Since then, the literature on paediatric chronic pain has grown substantially. This manuscript outlines a protocol for an updated systematic review to provide updated estimates of the prevalence of various forms of chronic pain in children and adolescence. The review will also examine the relationship between sociodemographic and psychosocial factors related to chronic pain prevalence.

Methods and analysis This review will follow Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. We will search EMBASE, PubMed, CINAHL and PsycINFO for observational studies published in English between 2009 and 2020 reporting population-based estimates of chronic non-disease-related pain prevalence in children or adolescents (age ≤19 years). Two independent reviewers will screen the titles and abstracts retrieved from the search based on predefined eligibility criteria. The full texts of relevant studies will then be assessed by two reviewers. Studies meeting inclusion criteria will be categorised according to the type of pain investigated: headache only, abdominal pain only, back pain only, musculoskeletal pain, combined pain, general pain and other pain. Data will be extracted using customised forms and studies will be assessed for risk of bias using a 10-item tool developed by Hoy et al (2012). A narrative synthesis will summarise the prevalence estimates of paediatric chronic pain and associated sociodemographic and psychosocial correlates. Meta-analyses and meta-regressions will be performed if the data permit.

Ethics and dissemination Ethical approval is not required. Findings will be disseminated through publication in an academic journal, presentations at conferences and in various media.

PROSPERO registration number CRD42020196690.

INTRODUCTION

Chronic pain, often defined as persistent or recurring pain or pain lasting longer than 3 months, is a common problem in childhood. Although numerous recent population-based studies have provided estimates of the prevalence of chronic pain in children and adolescents, the reported proportions have varied considerably across studies. For example, the prevalence of primary headache disorders in children and adolescents in recent population-based studies has ranged from 19.4% to 66.4%, while estimates of the prevalence of functional gastrointestinal disorders have varied from 4.6% to 31.2%. Due to the wide variability in the reported estimates, the current epidemiology of chronic pain in children and adolescents is unclear. The uncertainty regarding the number of children and adolescents impacted by chronic pain may limit the appropriate allocation of clinical services for this population, which are crucial given the pervasive and long-term consequences of chronic pain on young people.

Chronic pain can have a profound impact on children and adolescents. Children who experience chronic pain are at increased risk for depression and anxiety, school absences, social isolation and poorer quality of life. Approximately 5% of children with chronic pain experience severe levels of pain which significantly impact their daily functioning. Unfortunately,
many children with chronic pain become adults with chronic pain. In a prospective study of paediatric patients with functional abdominal pain, 35% continued to report recurrent abdominal symptoms when reassessed in adulthood. Similarly, in a 14-year follow-up study of adolescents with frequent headaches, 19% continued to report weekly headaches in young adulthood. These rates are similar to retrospective reports of chronic pain in childhood by adults with chronic pain. In a study of adult patients with chronic pain, 17% of participants reported their pain originated in childhood or adolescence.

The persistence of chronic pain from childhood to adulthood has significant social and economic consequences. For instance, children with chronic pain are at risk for opioid misuse and psychiatric morbidity in adulthood, and paediatric chronic pain is associated with high rates of outpatient appointments, emergency department visits and hospitalisations, all resulting in increased healthcare costs. The total annual cost of paediatric chronic pain in the USA is estimated to be $19.5 billion. The significant individual, social and economic burden of paediatric chronic pain, and its persistence into adulthood, demonstrates the importance of understanding the epidemiology of this disease in order to improve treatment and reduce the impact that chronic pain has on the lives of children and adolescents.

The most recent comprehensive review on the epidemiology of chronic pain in children and adolescents was published in 2011. This review estimated that the median prevalence of chronic pain in children and adolescents ranged from 11% to 38% depending on pain type and varied substantially across studies. The prevalence of chronic pain was found to be higher in girls and prevalence proportions increased with age. The review identified several psychosocial correlates of chronic pain in children and adolescents such as lower socioeconomic status, anxiety, depression and low self-esteem. However, other correlates of chronic pain in children and adolescents, such as sleep and post-traumatic stress disorder, have since been identified and were not consistently examined at the population level at the time of the past review. The review also identified several gaps in the understanding of the epidemiology of chronic pain in children and adolescents, including restricted age ranges and lack of longitudinal studies. Furthermore, at the time of the past review the quality of included studies was generally low to moderate and methodological limitations, such as inconsistent definitions of pain between studies, made it difficult to estimate overall prevalence proportions.

The literature on paediatric pain is growing exponentially; a recent bibliometric analysis revealed that there was nearly a 40-fold increase in the number of publications on paediatric pain from 1975 to 2010. Since the last comprehensive systematic review on the epidemiology of chronic pain in children and adolescents, numerous population-based studies estimating the prevalence of various forms of paediatric chronic pain have been published. A few recent studies examining the prevalence of certain forms of chronic pain, such as functional abdominal pain and headache, have also been conducted. However, in order to appropriately meet the clinical needs of children and adolescents with chronic pain, an updated review that estimates the proportion of various forms of chronic pain and examines key sociodemographic and psychosocial correlates of chronic pain in children and adolescents is needed.

This manuscript outlines a protocol for a systematic review to update a prior review synthesising the published literature on the prevalence of chronic pain in children and adolescents. Specifically, the objectives of this review are to: (1) provide updated estimates of the prevalence of various forms of chronic pain (headache, abdominal pain, back pain, musculoskeletal pain, combined pain, general pain and other pain) in children and adolescents; (2) provide an updated examination of sociodemographic (eg, age, sex, race) and psychosocial (eg, anxiety, depression, sleep) factors related to the prevalence of chronic pain in children and adolescents; and (3) assess study quality and identify gaps in the literature and areas for future research.

METHODS AND ANALYSIS

This systematic review protocol was prepared in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) guidelines (see online supplemental file 1). The study protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO) on 3 September 2020. In the event of an amendment to this protocol, the date of the amendment, a description of the change and the rationale will be documented and recorded in PROSPERO. The dates for this review are 14 May 2020–1 April 2021 (expected).

Search strategy

We will search the following electronic databases: EMBASE, PubMed, CINAHL and PsycINFO. The search terms will be comprised of three conceptual blocks: (1) pain terms (eg, musculoskeletal pain, back pain, headache, abdominal pain, recurrent pain); (2) paediatric terms (eg, child, adolescent, boy, girl) and (3) epidemiological terms (eg, epidemiology, prevalence, frequency). The searches will be restricted to English-language articles, human studies, and manuscripts published between January 2009 and June 2020 (the original systematic review included studies published up until 2009).

Eligibility criteria

Studies will be eligible for inclusion if they meet the following criteria:

1. Observational studies using a population-based sampling frame to estimate the prevalence of chronic pain in children or adolescents (study sample age ≤19 years).
2. Studies examining the prevalence of chronic pain in children and adolescents, defined as pain with a minimum duration of at least 3 months or pain that is described as chronic, persistent or recurrent. This definition was selected to align with current conceptualisations of chronic pain while allowing for flexibility to accommodate established diagnostic criteria for common childhood chronic pain conditions (eg, functional abdominal pain and migraine).
3. Studies published in peer-reviewed journals in English.
4. Studies meeting the following criteria will be excluded:
   1. Studies with sampling frames not deemed to be population based.
   2. Case studies, conference abstracts, dissertations, reviews, book chapters and qualitative studies.
   3. Studies reporting on the prevalence of chronic pain in adults (sample age is exclusively ≥20 years).
   4. Studies of non-human samples.
   5. Studies examining the prevalence of chronic pain in specific subpopulations, such as children and adolescents with chronic illnesses (eg, cancer, arthritis) or other health conditions (eg, cerebral palsy, muscular dystrophy).

Studies reporting on multiple populations (eg, adults and children), where data on one or more subpopulations that fit the eligibility criteria for this review can be separately identified, will be included and the relevant data will be extracted.

**Screening and data extraction**

Literature search results will be transferred to Covidence systematic review management software and duplicates will be removed. An initial title/abstract review of studies retrieved by the search will be independently conducted by two members of the study team to determine which studies potentially met the inclusion/exclusion criteria. Articles included from the title/abstract review phase will then be reviewed in full by two reviewers. The two reviewers will be blinded to each other's decisions. Discrepancies regarding the eligibility of a study will be resolved by consensus, and if necessary, through discussion with a third reviewer.

Data will be extracted from included studies using customised forms. Extracted information will include study design, location where the study was conducted, number of participants, participant demographics (eg, age, sex, race), study sample (eg, headache only, abdominal pain only, back pain only, musculoskeletal pain, combined pain, general pain and other pain). Additionally, the relationship between psychosocial factors (eg, sleep, anxiety and depression) and sociodemographic factors (eg, sex, age, race and indicators of socioeconomic status such as, but not limited to, household income, parental level of education and urban vs rural area of residence), and chronic pain in children and adolescents will be reviewed.

Depending on the heterogeneity of included studies, the prevalence proportions of chronic pain will be calculated using median prevalence proportions and/or meta-analysis. When at least two or more studies are comparable in terms of the study sample (eg, category of chronic pain) and methodology (eg, operationalisation of chronic pain), we will pool the effects to determine the prevalence proportion of chronic pain across studies. Similarly, if studies have used similar methods to examine the relationship between certain sociodemographic and/or psychosocial variables in comparable chronic pain samples, we will conduct separate meta-regressions to examine the relationship between these variables and chronic pain across studies.

**Quality assessment**

Two independent reviewers will assess study quality using the 10-item tool developed by Hoy et al.36 This tool was developed to assess external and internal validity of prevalence studies.36

Response options for each item are either ‘yes’ (indicating low risk of bias) or ‘no’ (indicating high risk of bias).36 The tool will be adapted for this review if necessary. Consensus will be reached by discussion between the reviewers.

**Data synthesis**

A narrative synthesis will summarise the prevalence proportions of chronic pain in children and adolescents in the following categories: headache only; abdominal pain only; back pain only; musculoskeletal pain; combined pain; chronic pain in children and adolescents will be reviewed.

**Implications of the review**

We anticipate that the results from this review will enhance our understanding of the current burden of paediatric chronic pain which may help inform treatment and allocation of clinical resources for this population. Furthermore, findings from this study will identify priority areas for research on the epidemiology of chronic pain to guide future research efforts. Through our planned knowledge translation efforts, findings of the review will be disseminated not only to clinicians and scientists, but also to patients and families, which may aid in public awareness and advocacy efforts.

**Patient and public involvement**

This protocol was designed in collaboration with a patient partner and coauthor. JM. JM will remain involved as a patient partner throughout all steps of the review.
