ABSTRACT

Objective To identify, appraise and synthesise evidence of interventions designed to promote family member involvement in adult critical care units; and to develop a working typology of interventions for use by health professionals and family members.

Design Mixed-method systematic review.

Data sources Bibliographic databases were searched without date restriction up to June 2019: MEDLINE, EMBASE and CINAHL; the Cochrane Central Register of Controlled Trials, Joanna Briggs and Cochrane Libraries. Back issues of leading critical care and patient experience journals were manually searched, as were the reference lists of included studies. All evaluation studies of relevant intervention activities were included; all research designs and outcome measures were eligible. Due to heterogeneity in interventions, designs and outcome measures, the synthesis followed a narrative approach. Service users met with the research team termly.

Results Out of 4962 possible citations, a total of 20 studies were included. The overall evidence base was assessed as moderate to weak. Six categories of interventions were identified: environmental unit changes (n=2), web-based support (n=4), discussion-based support (n=6), multicomponent support (n=4), participation in rounds (n=3) and participation in physical care (n=1). Clinical and methodological heterogeneity across studies hindered meta-analysis, hence a narrative synthesis was pursued. Six main outcomes were identified, grouped under two categories: (i) involvement outcomes: communication (*mean difference* ranged from 6.39 to 8.83), decision-making (*mean difference* ranged from -0.8 to 5.85), satisfaction (*mean difference* ranged from 0.15 to 2.48); and (ii) health outcomes: family trauma (*mean difference* ranged from -7.12 to 0.9), family well-being (*mean difference* ranged from -0.7 to -4), patient outcomes (*relative risk* ranged from 1.27 to 4.91). The findings from the qualitative studies were thematically analysed to identify features of the interventions that participants perceived to influence effectiveness. Synthesised into five overarching categories (practicality, development, interaction, reflexivity and bridging), these can serve as principles to inform the future design and development of more refined family member involvement interventions.

Conclusions Future interventions should be developed with much closer family member input and designed by considering the key features we identified. We call for

Strengths and limitations of this study

- We completed a comprehensive mixed-method systematic review of available evidence on interventions for family member involvement in adult critical care.
- We involved a service users and carers group throughout the systematic review process, which included 16 hours of in-depth group discussions.
- Study screening, selection, quality assessment and data extraction were completed independently and in duplicate by two review authors.
- Methodological and clinical heterogeneity across studies prevented us from pursuing a meta-analysis.
- Qualitative evidence was synthesised thematically to identify features of the interventions that participants perceived to influence effectiveness.

future interventions to be multilayered and allow for a greater or lesser level, and different kinds, of involvement for family members. Choice of intervention should be informed by a baseline diagnostic of family members' needs, readiness and preparedness for involvement. **PROSPERO registration** CRD42018086325.

BACKGROUND

Family member involvement in healthcare is recognised by policy-makers and the public as an invaluable aspect of healthcare provision. The move towards the more structured integration of family members is consistent with the call for greater patient-centred care, long invoked by a (2001) report from the Institute of Medicine.¹ Emphasising the potential benefits in actively involving family members in decision-making processes and care management was regarded as a key contributor to the reduction of the risk of medical error and a broader improvement in quality. The idea that a 'fully-engaged' public² should be encouraged has also been evident in UK contexts; however, governmental scrutiny over the proceeding decade revealed that this has yet to be comprehensively realised. Two strategic reports from NHS England^{3 4}

explored a practical move towards a healthcare system which is built around the patient, incorporating families representing a key means of achieving this.

For the purposes of the present review, family member involvement refers to the activities of different professionals to improve care by ensuring family members are involved in decision-making, sharing of information, power and responsibility for patient needs and choices. Family member involvement is especially relevant in the intensive care unit (ICU), where it can have profound consequences for care decisions, delivery and outcomes; this is partly because ICU patients are rarely in a position to communicate directly with clinicians and recollect their ICU experience, which means that the responsibility for this often lies with their family members. While this is a concern in healthcare systems worldwide, and especially in the UK, a recent mixed-methods study found there is still great variation in family satisfaction across ICUs in England, Wales and Northern Ireland.⁵

Studies over the past decade have confirmed that family members can have a positive influence on a patients' care and recovery from ICU; but also that family members themselves can be affected even after discharge.^{6–11} In particular, within the first few days after ICU admission, family members can show signs of anxiety, depression and stress; report difficulties in understanding the information clinicians try to communicate with them, and those who suffered a bereavement are at risk of generalised anxiety, panic attacks, depression and post-traumatic stress disorder (PTSD).⁷ For example, one study⁶ surveyed family members of patients who have been in ICU to find that 90 days after discharge more than a third (34%) of them suffered from PTSD symptoms. In addition, they noted higher rates (48%) among those family

members who indicated the information they were given was incomplete.

While there is a growing evidence base on patients, family members and clinicians' perceptions of involvement in ICU care, we are still missing a standardised, evidence-based approach to facilitate this process. Indeed, a recent scoping review¹⁰ sought to investigate the extent and range of literature on this topic, finding evidence of a growth in papers with over 100 reports identified. However, they did not seek to assess the quality of the evidence nor did they examine the type of interventions available, and key features that foster effectiveness. While this is an area of growing interest, we are still unclear about the range and quality of interventions available to promote family member involvement in ICUs.

METHODS

Our review sought to answer the following question: What are the available interventions, and which are most effective, for fostering family member involvement in adult critical care settings? Four objectives were set: (a) undertake a comprehensive and systematic search of published and unpublished studies reporting on interventions that promote involvement in adult critical care; (b) robustly assess the quality of empirical evidence for all included studies; (c) generate a detailed description and synthesis of interventions and their associated outcomes; and (d) classify interventions and outcomes in order to develop a typology of interventions, outlining key factors that support or impede involvement.

Study eligibility criteria

We included evaluation studies of any design, including experimental and quasiexperimental studies, as well as action research, case study and ethnographic designs. We considered reports of any kind of interventions as long as they were intended to promote the participation of family members in adult critical care. We included studies that reported on a mixture of relevant outcomes, including standard measures such as the Hospital Anxiety and Depression Score (HADS); and non-standard but important indicators such as family satisfaction. We excluded non-evaluation papers and those with populations, outcomes and settings that did not match our brief. One study reported on a bundled intervention including awakening and breathing coordination, delirium monitoring and management, early mobility and family-centred care; this study had to be excluded because we could not discern outcomes specifically linked to the family involvement component of the bundle.

Search for evidence

We searched (June 2019) MEDLINE, EMBASE, CINAHL and the Cochrane Central Register of Controlled Trials following a systematic approach without date restriction. We also performed searches for clinical studies through the WHO Trials Registry. We hand searched recent back

issues of key critical care and patient experience e-journals, scanned reference lists of identified reviews and included articles; searched our personal libraries and consulted with experts in the field. GoogleScholar was also searched. Non-commercially published (Grey) literature was sought through the OpenGrey and the GreyLit Report databases. A standardised search strategy was developed with the input of an information specialist and applied to all databases, utilising both MeSH and free-text terms (online supplemental file).

Data management, screening, extraction and quality assessment

Search results were imported into Covidence, the standard production platform for Cochrane Reviews. Two reviewers (AX and SF) independently screened all citations in duplicate against the inclusion criteria. Any disagreement was resolved through discussion or by involving a third reviewer (JP). Reasons for excluding papers read in full were recorded and a preferred reporting items for systematic reviews and meta-analyses

flowchart was completed. Standardised data extraction forms were used by two reviewers (SF and AX) to independently extract key information. Any disagreements found at this stage were also resolved through a consensus approach, or the involvement of a third reviewer (JP). We assessed each included paper for methodological rigour using an established rating approach utilised successfully in a number of previous mixed-method systematic reviews.^{12 13} This rating approach assesses ‘quality of study’ to consider: appropriate fit between study design/research questions and use of appropriate analyses; and, ‘quality of information’ to assess for a clear rationale for the intervention, good contextual information and risk of bias. Quality assessment was undertaken independently by two reviewers (AX and SF) in duplicate. For each quality domain, we described the procedures reported in the paper, using verbatim quotes as necessary.

Data synthesis

The overall approach to the synthesis followed a segregated methodologies approach.¹⁴ Accordingly, a separate

synthesis of quantitative and qualitative data was initially completed followed by a mixed-method synthesis. Quantitative studies were grouped depending on study design, and results summarised using descriptive statistics. Because heterogeneity precluded statistical combination through a meta-analysis, a narrative approach to the quantitative synthesis was pursued. Synthesis of qualitative data followed the best-fit framework approach, involving identification and grouping of thematic categories around factors influencing effectiveness of family member involvement interventions.¹⁵ The mixed-method synthesis utilised the quantitative data to inform on the measured effects, while the qualitative data informed on the perceived effects. In this way, the qualitative and quantitative data acted as complementary rather than as confirmatory of each other. A key element of the mixed-method synthesis was to classify interventions and outcomes in order to develop a typology of family involvement interventions in ICU. To develop the typology, we identified categories for the different interventions used in the studies by noting their distinguishing characteristics. We also formed and refined key family involvement features of the interventions, such as required time commitment from families and staff, opportunities and challenges, and cost. We tabulated these alongside an indication of the quality level of the current body of evidence, and the expected impact on important engagement and clinical outcomes. The typology was developed in collaboration with a service users and carers group over two face-to-face meetings, during which the overall findings of the review and ways of representing these visually were discussed. The resulting typology is illustrated in a matrix-like format presenting the intervention categories in a continuum from low to high involvement.

Patient and public involvement

From the outset, the development of this project was grounded in patient and public involvement (PPI) since family member involvement in ICU has been identified as a priority area for research by the James Lind Alliance (<http://www.jla.nihr.ac.uk>) through a priority setting partnership involving patients, carers and clinicians. ICU clinicians and patients raised our awareness on the lack of evidence-based advice on interventions that promote family involvement in ICU, and the challenges this introduces to daily practice. We included a PPI expert on our team (SB) and a frontline ICU clinician (MT) with whom we developed the project application and review protocol. We also invited feedback on our initial plans from the UK ICUSTeps Charity ensuring that the project was attuned to the sensitivities and concerns of service users. As part of the review process, a service users and carers group was established, the members of which were recruited through promotion in social media, the UK ICUSTeps charity and the National Institute for Health Research INVOLVE website. Consisting of eight ICU survivors and carers, the group was consulted through each step of the process and engaged in four strategically positioned meetings leading

to over 16 hours of focused and in-depth face-to-face discussions concerning the design, conduct, reporting and dissemination of the review. By having an engaged service user and carer group work with us throughout the completion of this review, we were able to look beyond the evidence by exploring the experiences and views of service users about the different interventions identified.

RESULTS

Overview of included studies

Search results

Out of 4962 possible citations, a total of 20 studies were included (figure 1). Published between 1989 and 2018, they were predominantly from North American contexts (n=17), and from a range of ICU settings including surgical, neuroscience, medical oncology and trauma ICUs. One study came from a French setting, and others from Swedish and Australian ICU settings.

Study designs

Most of the studies followed a quantitative approach (n=15), but we also included four qualitative and one mixed-methods study (see table 1). Specifically, quantitative studies included randomised-controlled trials, cluster-randomised and stepped-wedge trials, non-randomised before and after studies and prospective observational multicentre studies. Qualitative data from all studies came from semistructured interviews. Sample sizes across the quantitative studies ranged from 30 to 1106 family members; and in the qualitative studies from 10 to 54 family members.

Intervention types

Interventions were grouped based on their distinguishing characteristics (summarised in table 2), and positioned within a continuum of low to high involvement: (i) environmental unit changes (n=2),^{16,17} (ii) web-based support (n=4),¹⁸⁻²¹ (iii) discussion-based support (n=6),²²⁻²⁷ (iv) multicomponent support (n=4),²⁸⁻³¹ (v) participation in rounds (n=3)³²⁻³⁴ and (vi) participation in physical care (n=1).³⁵ Environmental unit change interventions consisted of complete structural redesign of an existing ICU with the specific objective being enhanced family member presence. Web-based and electronic interventions were approaches which utilised information and communication technology to facilitate information sharing and asynchronous communication. Discussion-based interventions generally consisted of one off or repeated face-to-face conversations which took place in the unit between family members and healthcare professionals. Multicomponent interventions comprised more than one technique to engage, educate and communicate with family members in the ICU. Family involvement in rounds interventions enabled the family members to attend and watch the daily rounds process, with opportunity to raise questions and clarify issues. Physical participation in care consisted of physical touch between

Table 2 Intervention characteristics

Author	Activity type	Intervention	Purpose	Procedure	Participants	Beneficiary	Outcomes
Allen <i>et al</i> 2017 ³²	Rounds based	Family member involvement in rounds	Engaging and integrating ICU patients' family members and surrogates on daily rounds	On admission to the ICU, a family member was invited to participate on daily rounds with the critical care team	Family members, nurses, physicians	Family members, nurses, physicians	<ul style="list-style-type: none"> ▲ Significantly increased family member knowledge ▲ Strengthened relationship between family members and doctors ▲ Nurses reported greater work enjoyment ▲ Improved communication ▲ Reduction in workload ▲ Increased support for patient and family-centred care ▲ Increased physician satisfaction post intervention
Almoosa <i>et al</i> 2009 ²²	Discussion based	Cardiopulmonary Resuscitation (CPR) discussions	The implementation of structured, informed CPR specific conversations with family members and surrogates from relevant physicians	Physician initiated CPR conversation about: chest compressions, electrical cardioversion, mechanical ventilation	Physicians, residents, fellows or family	Family members	<ul style="list-style-type: none"> ▲ Satisfaction with CPR discussions was higher after the intervention
Choi and Bosch 2013 ¹⁶	Unit design	Patient and family-centred unit design	Unit redesign undertaken to enable physical space to more broadly facilitate family interaction with patient, and family interaction with staff	The intervention unit included larger spaces and more comfortable accommodations for visitors	Family members	Family members and patients	<ul style="list-style-type: none"> ▲ Increased family interactions with patient ▲ Increased family interactions with staff
Cray <i>et al</i> 1989 ²⁸	Multicomponent	Family intervention programme	Multicomponent intervention to enhance family involvement in, and understanding of, their loved one's condition in ICU	Intervention components included: family conference, telephone conversation, visit by nurse, follow-up visit to the intermediary care unit	Family members, clinical nurse specialists	Family members	<ul style="list-style-type: none"> ▲ Strong agreement that the intervention helped family members to understand their loved one's illness and benefit other families ▲ High satisfaction with intervention components
Dalal <i>et al</i> 2016 ¹⁸	Web based/electronic	Patient-centred toolkit (PCTK)	The PCTK was a suite of web-based patient-facing and provider-facing tools designed to facilitate collaborative decision-making by providing access to tailored educational content and facilitating patient-provider communication	The PCTK was accessible by patients, caregivers and providers from any web-enabled device connected to the hospital's secure intranet	Patients and caregivers	Patients and family members	<ul style="list-style-type: none"> ▲ The majority of patients and caregivers surveyed were satisfied or extremely satisfied with the intervention
Davidson <i>et al</i> 2010 ²⁹	Multicomponent	Family-support programme, based on facilitated sensemaking	A systems-based patient-centred care and engagement programme	The intervention consisted of two main components: personalised instruction and provision of family visiting kits	Family members, Clinical nurse specialists	Family members	<ul style="list-style-type: none"> ▲ High rate of instrument reliability ▲ A breakdown of the top 10 needs of family members ▲ A ranking of interventions' helpfulness ▲ Identification of any additional needs

Author	Activity type	Intervention	Purpose	Procedure	Participants	Beneficiary	Outcomes
Rippin <i>et al</i> 2015 ¹⁷	Unit design	Family-centred unit (FCU) design	Unit designed to prioritise and engage the family in the ICU context	The FCU physically integrated family into the fabric of the unit. Nurses worked between centralised nursing stations and decentralised alcoves just outside patient rooms for improved monitoring and safety. Rooms were larger (245 sq ft) with more space around the bedside	Nurses and family members	Family members	<ul style="list-style-type: none"> ▲ Reduction in problematic bedside copresence (or overcrowding) ▲ A continuity of preintervention distribution patterns in which nurse and family remained clustered in their respective 'domains' ▲ Nurse perspectives which acknowledged the unpredictability and complexity of the ICU and the subsequent mixed results which this newly implemented unit design encouraged
Shaw <i>et al</i> 2014 ²⁷	Discussion based	Multidisciplinary team (MDT) training to enhance family communication in the ICU	The training material was selected to improve communication. The training was also designed to foster team building and improve collaborative relationships among clinicians from multiple disciplines	Training included how to conduct and participate in patient/family conferences, addressing goals of care and giving critical information in the intensive care setting so that all caregivers might speak to patients and their families with a common voice. The training was designed to address known drivers of family satisfaction, as well as to address each of the 21 items being measured in the staff confidence survey	ICU team members	MDT team members and family members	<ul style="list-style-type: none"> ▲ Staff confidence and family satisfaction were shown to significantly improve
Weber <i>et al</i> 2018 ³⁴	Rounds based	Family rounds	To improve family satisfaction in ICU experience by integrating them into rounds processes	After each session, the nursing leader recorded (1) whether family rounds occurred (2), how many families participated, and (3) how many patients the ICU team had rounded on that morning	Nursing staff	Family members	<ul style="list-style-type: none"> ▲ Family reported improved satisfaction with decision-making, frequency of communication, receiving emotional support and with coordination of care ▲ Percentage improvements in satisfaction scores were not large enough to reach statistical significance
White <i>et al</i> 2018 ³¹	Multicomponent	Multicomponent family-support intervention	Collaborative intervention between nursing staff and family members designed to support caregivers in the ICU	Nurses received advanced communication training. A family-support pathway was instituted. Intensive support for implementation was provided to each ICU by a quality-improvement specialist to incorporate the family-support pathway into clinicians' workflow	Nursing staff, ICU team, family members	Family members and nursing staff	<ul style="list-style-type: none"> ▲ Significant improvements were noted with family satisfaction regarding: the quality of communication with clinicians, and ▲ The intervention led to an average reduction in the length of stay in the ICU of 3 days

ICU, Intensive care unit; PCP, Primary care physician.

family members and patients being utilised for reciprocal benefit.

Quality of evidence

The overall evidence base was assessed to be moderate to weak, with only a few exceptions of high-quality quantitative and qualitative studies (tables 3 and 4). The main weaknesses of the quantitative studies were related to inadequate randomisation and blinding, and lacking a control group for comparison purposes. The qualitative studies were in the main of a better quality, with key weaknesses being related to inadequate researcher reflexivity and theorisation of findings.

Quantitative results

Six main outcome categories were identified from the studies analysed for the review, grouped under two groups. Involvement outcomes: communication, decision-making, satisfaction; and health outcomes: family well-being, family trauma, patient outcomes. A summary of key results is provided below, with detailed reporting of outcome measures available in the tables; in online supplemental tables 1–6 the outcome measures are presented according to intervention type.

Involvement outcomes

Communication (table 5): improved communication was considered as an outcome in five studies,^{27 31–34} the majority of which involved family participation in rounds, reporting on four measurement tools. Three studies^{27 33 34} utilised the Family Satisfaction ICU (FS ICU 24) tool, specifically reporting on three dimensions: honesty of information, frequency of doctor communication and frequency of nurse communication. One study³¹ reported on the Quality of Communication tool and another used a self-developed questionnaire.³² Mean improvements were found in all studies, although not all results reached statistical significance. The biggest effect was seen on the frequency of doctor communication, with one study of family participation in rounds showing a statistically significant improvement of 60% (relative risk, RR: 1.60, CI: 1.18 to 2.17, $p=0.004$).³³

Decision-making (table 6): six of the included studies^{21 22 25 27 33 34} looked at decision-making as an outcome, most of which were discussion-based interventions, through six measurement tools. The ‘decision making’ subscale of the FS ICU 24 revealed improvements in three studies although only one,²⁷ targeting the whole interprofessional team, found a statistically significant result (MD: 5.85, $p=0.05$). Inclusion in decision-making was also considered, as the percentage change in family members reporting complete satisfaction or giving the highest score, with one study²⁵ which involved the patient’s primary physician showing a statistically significant improvement of 23% (RR: 1.23, CI: 1.03 to 1.49, $p=0.05$). Studies also noted improvements with regard to ‘control over patient care’ (RR: 1.31, CI: 1.07 to 1.61, $p=0.02$),²⁵ ‘support in decision-making’ (RR: 1.39, CI:

1.09 to 1.79)²¹ and ‘share in decisions about care planning’ (23%, RR: 1.52, CI: 1.03 to 2.24, $p=0.009$).²¹

Satisfaction (table 7): satisfaction was considered as an outcome in nine studies^{18 19 21 25 27 28 31 33 34} using six different measures, and reporting on a mixture of discussion-based, rounds-based, multicomponent-based and web-based interventions. The majority of studies ($n=4$) measured family satisfaction with care using the FS-ICU, while the remaining studies used self-developed tools. One of the studies¹⁹ also used the HCAHPS (Hospital Consumer Assessment of Healthcare Providers and Systems) Survey. This is a national, standardised, publicly reported survey of patients’ perspectives of hospital care in the USA. Mean improvements on the FS ICU were found in all studies, ranging from 1.49 to 5.7, although only one¹⁹ which used a web-based engagement intervention reached statistical significance (MD: 5.7, CI: 2.31 to 9.09, $p<0.05$). Statistically significant improvements were also noted on the HCAHPS (RR: 1.33, CI: 1.10 to 1.55, $p<0.05$).¹⁹

Health outcomes

Family well-being was considered through measurements for anxiety and depression.

Anxiety (table 8): four studies, which encouraged family participation in discussions and personal care, considered anxiety as an outcome^{23 26 31 35} using three different ways for measurement. Three studies^{23 31 35} used the HADS. The fourth study²⁶ used the Generalised Anxiety Disorder Assessment (GAD-7). All four studies identified a reduction in family members’ anxiety scores post the intervention, with the effect ranging from -0.34 to -4 . The minimal clinically important difference of HADS has been suggested to be between -1.5 and -2 ; therefore, the reduction noted in these papers could be of clinical significance. However, only two of these studies found statistical significance.^{23 35}

Depression (table 9): depression was an outcome also reported by three of the above studies^{23 26 35} using two measures. Two studies^{23 35} used the depression subscale of the HADS, while another²⁶ used the Patient Health Questionnaire (PHQ-9). Both studies that used the HADS identified a reduction in depression among family members, although only one²³ reached statistical significance ($p=0.04$) with a median reduction of 3.5. Results on the PHQ-9 also showed a statistically significant mean reduction in scores at 6 months (MD: -2.3 , CI: -4.30 to -0.42 , $p=0.01$).²⁶

Family trauma (table 10): three studies considered the impact of interventions (multicomponent-based, web-based and discussion-based) on family member ICU-induced trauma using four different measurement tools:^{23 26 31} PTSD Checklist, Impact of Event Scale (IES) and Peritraumatic Dissociative Experience Questionnaire. All three studies identified a trend showing a beneficial effect of family involvement interventions on severity of trauma through reduced severity scores, ranging from a reduction of -3 to -7 points on the various scales; however, none of these results reached statistical significance.

Patient outcomes (table 11): three kinds of patient outcomes were reported in three studies involving multicomponent-based, web-based and discussion-based interventions: patient mortality,^{22 31} adverse events¹⁹ and length of stay.^{19 31} A statistically significant increase in mortality was reported in two studies; specifically one study found an actual percentage increase in the intervention group of 31% (RR: 4.91, CI: 1.55 to 15.51, $p < 0.05$),²² while the other of 7.5% (RR: 1.27, CI: 1.09 to 1.48, $p = 0.008$).³¹ A relative reduction in adverse events per 1000 patient days of 29% was also reported⁹ with an actual mean difference of -17 (CI: -6.95 to -27.05, $p < 0.05$). Length of stay was examined in two studies with conflicting results: one reported a statistically significant reduction (MD: -0.77, CI: -0.69 to -0.87, $p < 0.001$),³¹ while another did not find any statistically significant difference.¹⁹

Qualitative results

Features that influence effectiveness

The findings from the qualitative studies ($n = 5$) were analysed thematically to identify features of the interventions that participants perceived to influence effectiveness. These included accessibility, simplicity, supplementarity, contextualisation, interprofessionalism, consistency, relationship and confidence development. Synthesised into five overarching categories, these can serve as principles to inform the future design and development of more refined family member involvement interventions in ICU: (a) practicality, (b) development, (c) interaction, (d) reflexivity and (e) bridging. We present a high-level summary of these below, with a more detailed qualitative report to be made available in a forthcoming publication.

Practicality: identified as a theme in three studies,^{20 23 24} this included intervention accessibility, simplicity, long-term application and repetition. Practicality points to effective interventions needing to be readily available with clear instructions, which are as close to universally identifiable as possible. This may enable the intervention to be used as many times as necessary, benefiting family members over and beyond an individual encounter.

Development: in four studies^{17 20 24 30} developing family members' contextual knowledge, or insight, was particularly valuable for effective intervention delivery. Insight was key to developing shared understanding among all those engaged in the treatment process. Insight should go beyond an understanding of the patient's condition to encompass the diverse perspectives of healthcare professionals and the emotional strain which family members naturally undergo.

Interaction: three studies^{17 20 24} noted that interventions, either explicitly or implicitly, should encourage verbal and physical interaction between clinicians and family members. However, interprofessional discussions among ICU clinicians, and specifically between medical and nursing staff, appeared equally important. Interventions that foster quality interaction at all levels appear essential for the family to be coherently integrated into the structure of the ICU.

FS ICU, family satisfaction intensive care unit; MD, mean difference; RR, relative risk.

Reflexivity: while effective interventions bring people together, three studies^{17 23 24} noted they should also benefit the individual family member, who has the opportunity for personal growth in the path towards meaningful family member integration. Specific examples of reflexivity in the featured interventions were identified in the confirmatory exchanges between family members and healthcare professionals, as family members were able to explore their own role within the ICU, the relationships which they had independently developed with their clinicians and how they could use this unique knowledge as a form of leverage in their communication with ICU professionals.

Bridging: effective interventions should also provide key and otherwise unavailable pathways to encourage family member integration. In two studies,^{20 23} the supplementary capacity, which effective interventions offer was of particular value when consistent or predictable communication could not be guaranteed. While information

availability is important, acknowledging the many difficulties which family members themselves face, and offering ways to overcome these, may ultimately enhance integration and experience.

Proposed typology

Utilising the learning gained from the current review, and the insights of our service users and carers group, we propose a typology of interventions (figure 2) to be considered when promoting family member involvement in ICU. Presented in a matrix, we position types of interventions along a continuum of low to high involvement (environmental unit changes, web-based support, discussion-based support, multicomponent support, participation in rounds and participation in physical care) along with their key characteristics (type of ICU, family time commitment, professional input, cost, opportunities and challenges), level of evidence (low, moderate and high) and impact on key involvement and health outcomes (satisfaction, decision-making, communication, family well-being,

Table 6 Decision-making outcome measures

Study	Huang <i>et al</i> 2018	Shaw <i>et al</i> 2014	Weber <i>et al</i> 2018	Jacobowski <i>et al</i> 2010	Huffines <i>et al</i> 2013	Almoosa <i>et al</i> 2009
Intervention measure	Primary physician involvement	Team training	Family rounds	Family rounds	Support care algorithm	Cardiopulmonary resuscitation (CPR) discussions
FS ICU 24—decision-making	Mean (SD) Control: 80.07 (12.76) Intervention: 81.06 (15.1) Change: 0.99, p=0.16 CI: -3.00 to 4.98	Mean score Pre: 77.47 Post: 83.32 Change: 5.85, p=0.05*	Mean score (SD) Control: 85.1 (16.3) Intervention: 88.6 (14.6) Change: 3.5, p=0.20 CI: -1.98 to 8.98			
Inclusion in decision-making	% completely satisfied Control: 61.4% Intervention: 75.9% Change: 14.5%, p=0.05* RR: 1.23, CI: 1.03 to 1.49			% highest score Pre: 66% Post: 76% Change: 10%, p=0.12 RR: 1.15, CI: 0.96 to 1.38		
Control over patient care	% completely satisfied Control: 55.6% Intervention: 73.6% Change: 18%, p=0.02* RR: 1.31, CI: 1.07 to 1.61					
Support in decision-making				% highest score Pre: 49% Post: 69% Change: 20%, p=0.005* RR: 1.39, CI: 1.09 to 1.79		
Share in decisions about care planning					% scoring excellent Pre: 45% Post: 68% Change: 23%, p=0.009* RR: 1.52, CI: 1.03 to 2.24	
Time to decision						Days mean (SD) Control: 7.4 (3.2) Intervention: 6.6 (6.5) Change: -0.8 days CI: -1.48 to 3.08

family trauma and patient outcomes). We completed an initial face and content validation with our project's service users group consisting of ICU survivors and family members, and advisory board consisting of ICU professionals, but would still caution that the typology remains in need of further empirical validation in different ICU settings.

DISCUSSION

The diverse nature of the family involvement interventions we identified, the heterogeneity of research designs

found and the varying methodological quality of available studies meant there was not a single intervention that stood out as the recommended way forward. Overall, the available evidence suggests that rounds-based interventions can benefit communication outcomes; multi-component and web-based interventions can increase family satisfaction and, discussion-based interventions can benefit decision-making and family well-being. However, interventions can be of varying cost, require different kinds and levels of input and time commitment

from clinicians and family members, and impact on different kinds of outcomes. Given the current state of the evidence, we discourage proposing a single intervention as the ‘gold standard’ and instead encourage the use of our typology to inform decisions based on individual ICU teams’ context, needs and available resources.

At this stage, we suggest our typology is used as a reflective tool to aid ICU teams make evidence-informed decisions about potential interventions they may wish to consider adopting locally. In the first instance, teams are advised to discuss the kinds of engagement and/or clinical outcomes their unit wants to improve as a priority so they can focus and limit their choice of intervention types.

They could then consider the evidence level, cost and key opportunities and challenges offered by each intervention type to help them make fully informed decisions as well as manage expectations. Finally, they could consider the time investment expected of ICU professionals and of family members for the different intervention types; for example, in geographically remote areas where family visiting is a challenge and staff shortage is significant, the team may favour trialling an intervention with less time commitment.

Through focussing on the different types of available interventions, their associated involvement and clinical outcomes, features perceived to influence effectiveness,

and proposing an overarching typology of family involvement interventions, the current review makes a significant contribution to the available literature. Past review work in this area largely focused on interventions that can support family members of critically ill patients;^{36–39} these included providing care and treatment options for family members to counter the negative effects arising out of a loved one being hospitalised, or dying, in ICU. Available

guidelines often suggest a long list of initiatives to support family members without full consideration or instruction on the contextual requirements of these suggestions or the kind of impact likely to be achieved by these. While prior reviews concluded, as have we, that the evidence in this field needs development and strengthening, these did not offer a granulated analysis of the evidence level for different kinds of interventions or presented these in

a visual and user-friendly way to inform future work. Such work has helped spark the current movement around family involvement in ICU but remains somewhat limiting in that it does not adequately distinguish between family *support* and family *involvement*, often conflating the two. Consequently, conclusions of past work lack clarity on what can be done to involve as well as support family members.

We expect our typology to introduce some much-needed clarity in this field of research, as well as inform

the development of future interventions and research studies. Importantly, the typology may be used by individual ICUs to inform discussions among professionals, and with family members, about which kinds of family involvement interventions they may wish to adopt, trial and implement in their units.

We add to this field of research by adopting strict methodological standards in the current review, to reduce risk of reviewer bias and strengthen transparency. Many of the available guidelines for family involvement in ICU

are based on a scoping review methodology, which can be methodologically limiting especially in lacking independent and duplicate screening, data extraction and quality assessment; though with notable exceptions.⁴⁰ A further way in which we sought to build on others' work was by examining the full spectrum of involvement interventions, rather than focussing on singular aspects such as decision-making. Moreover, we opted to include service users throughout the review process, rather than limiting their involvement to the final stages of peer checking results. This allowed our service users to contribute throughout the process, see how the review was developing, appreciate the technical side of the review process and of the available evidence and importantly to contribute actively in the development of the final typology.

The involvement of a service users and carers group led to us to identify a key, fundamental flaw of existing family involvement interventions and research: in our assessment, these tend to treat family members as a homogeneous group of individuals, rather than as heterogeneous units. Specifically, different family members may have different involvement needs and preferences influenced by their previous experiences, knowledge, mental and physical health and socioeconomic state. In addition, the notion of a family member extends beyond the 'next of kin' or 'personal consultee' to encompass extended family, carers and friends. Moreover, our service users emphasised that the dynamics within family units are

crucial to shaping the experience, benefit and satisfaction of family members with ICU care and their level of involvement.

Current family involvement interventions and initiatives appear to be applied in ICUs following a blanket approach, without adequate consideration of particular family members' needs and preparedness for involvement. This may result in some family members benefiting while others experiencing harm, which goes some way in explaining the wide CIs identified in our review that often cross the line of no difference. Indeed, within the PTSD literature, systematic reviews have long concluded that interventions applied universally to victims of trauma, such as compulsory debriefing, should cease and be replaced with a 'screen and treat' model.⁴¹ We therefore invite researchers and clinicians to consider the aforementioned issues carefully in future initiatives for involving family members in ICU.

The current review should be considered in the context of its limitations. These include lack of a meta-analysis, and research published in languages other than English, and from lower- and middle-income countries.

CONCLUSION

We examined interventions for family member involvement in ICUs, assessed the quality level of the available evidence, presented key results grouped by kinds of outcomes and interventions, and identified key features stakeholders

Intervention Types	Features	ICU setting	Family time commitment	Professional input	Opportunities & Challenges	Cost	Evidence level	Engagement outcomes			Clinical outcomes		
								Satisfaction	Decision making	Communication	Wellbeing	Trauma	Patient outcomes
Environmental unit changes Unit change interventions consisted of complete structural redesign of an existing ICU with the objective being enhanced family member presence		General	Low	Low	+ Communication + Interaction - Exposure - Privacy	High	Low	Low impact	Very low impact	Low impact	Very low impact	Very low impact	Very low impact
Web-based support Web based and electronic interventions were approaches which utilised information and communication technology to facilitate information sharing and asynchronous communication		General/ Specialist	Moderate	Moderate	+ Knowledge + Efficiency - IT proficiency	Moderate	Moderate	High impact	Low impact	Very low impact	Very low impact	Very low impact	Low impact
Discussion-based support Discussion based interventions generally consisted of one off or regular face to face conversations which took place in the unit between family members and healthcare professionals		General/ Specialist	Moderate	High	+ Support + Wellbeing + Decision making - Training	Moderate	High	Moderate impact	Very high impact	High impact	Moderate impact	Moderate impact	Low impact
Multicomponent support Multicomponent interventions comprised more than one technique to engage, educate and communicate with family members in the ICU		General/ Specialist	High	High	+ Family trauma + Pt outcomes - Complexity - Resources	High	High	Moderate impact	Very low impact	Low impact	Moderate impact	Low impact	Moderate impact
Participation in medical rounds Family involvement in rounds interventions enabled the family members to attend and watch the daily rounds process, with opportunity to raise questions and clarify issues		General ICU	High	Moderate	+ Knowledge + Efficiency - Time - Satisfaction	Low	High	Moderate impact	Very low impact	High impact	Low impact	Very low impact	Very low impact
Participation in physical care Physical participation in care interventions consisted of physical touch between family members and patients being utilised for reciprocal benefit		General ICU	High	Low	+ Satisfaction + Wellbeing - Confidence	Low	Low	High impact	Very low impact	Very low impact	Moderate impact	Very low impact	Very low impact

Figure 2 Typology of family involvement interventions.

perceived to influence intervention success. We summarised our results in the form of a typology, which we offer here as a first step towards developing a more systematic programme of research on interventions for family involvement in ICU. Based on the learning gained from the current review, we argue that future interventions should be developed with much closer family member input and designed by considering the key success features we identified. Importantly, we call for future interventions to be multilayered to allow for a greater or lesser level, and different kinds, of involvement for family members; the decision of which should be informed by a baseline diagnostic of family members' readiness and preparedness for involvement.

Acknowledgements We are grateful to our Expert Advisory Board and patient advisers, members of our Service Users and Carers Group, for their invaluable insight and support throughout this review. We owe intellectual debt to the late Professor Scott Reeves who generously supervised this project until his untimely passing in May 2018.

Contributors AX was responsible for conceiving the review, developing the review question and methodology, leading the funding application and coordinating the project. SF and JP were responsible for developing and executing the search strategy. AX, SF and JP were responsible for reference screening, quality assessment, data extraction and management. AMR, MT and SB gave advice throughout the project and contributed to data interpretation. AX and SF were responsible for the statistical inferences and qualitative synthesis, respectively. SF and AX led the development of the first draft of the manuscript. SB, JP, MT and AMR gave editorial comments on the draft manuscript. AX is the guarantor of the review. AX, SF, JP, SB, MT and AMR read and approved the manuscript.

Funding This paper presents independent research funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Reference Number PB-PG-0416–20021).

Competing interests None declared.
