Cost-effectiveness of emergency preparedness measures in response to infectious respiratory disease outbreaks: a systematic review and econometric analysis

Constantine Vardavas,1 Katerina Nikitara,1 Konstantinos Zisis,1 Konstantinos Athanasakis,2 Revati Phalkey,3 Jo Leonardi-Bee,3 Helen Johnson,4,5 Svetla Tsolova,5 Massimo Ciotti,5 Jonathan E Suk5

ABSTRACT

Objectives Respiratory infectious disease outbreaks pose a threat for loss of life, economic instability and social disruption. We conducted a systematic review of published econometric analyses to assess the direct and indirect costs of infectious respiratory disease outbreaks that occurred between 2003 and 2019.

Setting Respiratory infectious disease outbreaks or public health preparedness measures or interventions responding to respiratory outbreaks in OECD countries (excluding South Korea and Japan) so as to assess studies relevant to the European context. The cost-effectiveness of interventions was assessed through a dominance ranking matrix approach. All cost data were adjusted to the 2017 Euro, with interventions compared with the null. We included data from 17 econometric studies.

Primary and secondary outcome measures Direct and indirect costs for disease and preparedness and/or response or cost-benefit and cost-utility were measured.

Results Overall, the economic burden of infectious respiratory disease outbreaks was found to be significant to healthcare systems and society. Indirect costs were greater than direct costs mainly due to losses of productivity. With regard to non-pharmaceutical strategies, prehospitalisation screening and the use of protective masks were identified as both an effective strategy and cost-saving. Community contact reduction was effective but had ambiguous results for cost saving. School closure was an effective measure, but not cost-saving in the long term. Targeted antiviral prophylaxis was the most cost-saving and effective pharmaceutical intervention.

Conclusions Our cost analysis results provide evidence to policymakers on the cost-effectiveness of pharmaceutical and non-pharmaceutical intervention strategies which may be applied to mitigate or respond to infectious respiratory disease outbreaks.

INTRODUCTION

Emerging, re-emerging and endemic respiratory and influenza-like infectious diseases represent a threat for loss of life, economic instability and social disruption as they can rapidly spread within communities and across countries, affecting the whole globe. Annually, it is estimated that 5%–15% of the population will suffer from influenza-related respiratory tract infections, while 3–5 million people face severe illness due to influenza.1 In 2018, a total number of 109.5 million influenza virus episodes were identified among children under 5 years globally, with approximately 34,800 overall deaths. In Europe, seasonal influenza is estimated to lead to 4–50 million symptomatic cases and 15,000–70,000 deaths annually; however, this may differ between years, as the severe 2017/2018 influenza season led to an estimated 152,000 deaths in Europe alone.23
In order for robust national preparedness systems and response strategies to outbreaks to be established in the Europe, it is crucial for public health officers to receive recent data of the health impact and the economic burden of respiratory infectious disease outbreaks in contrast to emergency response and preparedness actions. This evidence will ensure well-informed decisions regarding, among others, the proper allocation of resources. To this extent, although there is substantial literature from previously published systematic reviews on the value of public health emergency preparedness, they either refer to an older timeframe or use mathematical models to predict the effectiveness and cost-effectiveness of measures. Hence, there is limited recent information on the economic evaluations of infectious respiratory disease outbreaks that provide an overview of the cost effectiveness of response measures.

Within the above context, the aim of this systematic review of econometric analyses was to assess the economic impact of response and preparedness measures when contrasted with the cost of infectious respiratory disease outbreaks. We further synthesise the cost-effectiveness for each intervention using a dominance ranking matrix (DRM) approach.

METHODS

Search strategy and selection criteria

A comprehensive systematic literature review of published econometric analyses was conducted between July and August 2019 using the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines and the Consolidated Health Economic Evaluation Reporting Standards (CHEERS) to identify peer-reviewed articles using two biomedical literature databases (PUBMED and EMBASE) and two economic literature databases (ECONLIT, IDEAS REPEC). The search strategy was designed for a broader study aiming to identify econometric studies on all types of infectious diseases, but due to the outbreak of COVID-19, and for the purposes of this specific article, we retained only those referring to respiratory infectious diseases. The complete search strategy and search terms are available in online supplemental appendix 1.

The inclusion criteria were as follows:

- Exposure: respiratory infectious disease outbreaks or public health preparedness measures or interventions responding to respiratory outbreaks in OECD countries (excluding Asian countries South Korea and Japan due to the wide cultural differences with the EU context as this study was performed under contract for the European Center for Disease Prevention and Control (ECDC)).

- Comparator: (i) no intervention (cost of inaction) or current practice, (ii) cost of preparedness versus cost of response (for studies reporting cost and benefit of public health preparedness).

- Outcome measures: direct and indirect costs for disease and preparedness and/or response or cost-benefit and cost-utility. Typical outcome measures of economic evaluations included: life years gained or cost per life-year gained with the intervention under investigation when incremental costs are combined, cases averted, monetary outcomes.

- Perspective: all direct and indirect costs pertaining to all relevant perspectives (eg, individual, hospital, insurance and societal—including national and regional) and all direct and indirect costs pertaining to all relevant perspectives according to York Health Economics Consortium (health system perspective, including hospital, public health units; societal perspective; governmental perspective).

- Study designs: all relevant analytical epidemiological designs which estimate cost either as full economic evaluation studies, including cost-minimisation, cost-effectiveness, cost-utility and cost-benefit studies; cost-outcome and economic modelling studies or partial economic evaluations.

- Timeframe: from 2003 until August 2019, to reflect the timepoint from the 2003 SARS outbreak and onward—this review refers to the pre-COVID-19 published evidence.

Studies that met the above inclusion criteria but did not report or perform any econometric analysis were excluded.

Data analysis and extraction

Studies identified from the searches were uploaded into a bibliographic database in which duplicate entries were removed. Initially, a pilot training screening process was used, where a random sample of 100 titles and abstracts were screened independently for eligibility by four reviewers (KN, KZ, RP, JLB) to enable consistency in screening and identify areas for amendments in the inclusion criteria. Following this, a random sample of 50% of titles and abstracts was screened independently by two reviewers. Since a high measure of inter-rater agreement was achieved (percentage agreement >88.7% and/or Cohen’s Kappa >0.646), the remaining titles and abstracts were screened for eligibility by one reviewer. Where insufficient information was available in the title and abstract to make a decision, the full-text article of the document was retrieved for further inspection. Full-text documents of potentially eligible studies were retrieved for the records marked for inclusion. All full-text documents were independently double-screened by two reviewers, and inter-rater agreement measures were calculated at 88.3%. Disagreements in every step of the process were subsequently discussed and agreed on. Documents that passed the inclusion criteria on the basis of the full-text screening were included in the current review.
Appraisal of methodological quality
For evaluating the methodological quality of the included studies, the Consensus on Health Economic Criteria (CHEC) checklist was used. This specific tool has been designed for the assessment of full economic evaluations and includes 19 items (questions) with answers of ‘Yes’ or ‘No’. For each positive answer on full economic evaluation studies, a single point was being assigned for the methodological quality, with a maximum score of 19. For the quality appraisal of partial economic evaluations, we used items from the CHEC checklist that were applicable—hence, the maximum score was 16. The quality appraisal process was completed by two reviewers, with a percentage of agreement in the three pilot studies, initially assessed by both, of 83.7%.

Comparative economic analysis approach
All cost data were adjusted to a common currency (Euro in 2017 (€)) and price year using the Campbell and Cochrane Economics Methods Group–Evidence for Policy and Practice Information and Coordinating Centre cost converter. We adjusted the original estimate of cost from the original price year to a target price year adjusted cost estimate from the original currency in 2017 (€). All cost data were adjusted to a common currency (Euro). Comparing economic analysis approach initially assessed by both, of 83.7%.

RESULT
The initial study search yielded 20,513 studies after removal of the duplicates and according to the specified selection criteria, only 66 were further assessed for eligibility via full text. Through the assessment of the full texts, 52 studies were excluded for the following reasons: inadequate data on costs and/or cost-effectiveness (n=2), they were reviews (n=15), not referring to respiratory outbreaks (n=29), not referring to outbreaks of infectious diseases (n=2) and conference abstracts with no full text available (n=4). Additionally, three full-text papers were identified through the screening of the reference lists of the selected manuscripts, and hence, a total number of 17 econometric studies were considered in our analysis. The flowchart of the study selection process is presented in figure 1.

Overall, 11 out of the 17 studies were of high methodological quality (>80%), 5 were categorised as of good quality (60%–80%) and only 1 was of medium quality (40%–60%) due to missing quality criteria not mentioned by the authors including the comparative intervention, sensitivity analysis, incremental costs and outcomes. Online supplemental appendix 2 presents the overall quality appraisal score, for studies related to cost of infectious disease outbreaks and for sources related to preparedness, preventive and response measures concerning infectious disease outbreaks. The quality appraisal of partial and full economic evaluation studies is in online supplemental appendices 3 and 4, respectively. It is important to note that for the studies where a partial economic evaluation was performed, we only performed the calculations for the items of the quality appraisal tool that were applicable.

Comparative cost analysis of infectious respiratory disease outbreaks
Regarding infectious respiratory disease outbreaks, six studies were included. All studies referred to influenza as the disease, either relating to pandemic H1N1 or seasonal Influenza B. Geographically, the studies...
were performed in the USA, Spain, France, New Zealand and Australia. Five out of the six studies were observational in design (cross-sectional or retrospective) and used collected data; one study was based on a simulation model. Similarly, five out of the six studies assessed costs from a healthcare system perspective, however, societal (n=3), governmental (n=1) and payer (n=1) perspectives were also assessed. Discounting in costs was not necessary for any of the included studies as the implementation timeframe had a duration of less than 1 year, and sensitivity analyses were performed only in three studies. A detailed description of the characteristics of the included illness studies is presented in online supplemental appendix 5.

Table 1 presents an analytical overview of the direct and indirect costs associated with influenza outbreaks. Direct costs mainly refer to medical and healthcare costs related to the outbreaks, along with the costs of response measures. Indirect costs included the loss of income, the loss of business and the loss of productivity. The overall direct costs reported in the studies were calculated at the patient level where possible.

The most recent study was a simulation study by Prager et al, in which multiple scenarios were assessed through simulation models for the US population so as to estimate the total economic burden of pandemic influenza outbreaks in the USA, taking into account both the scenario of an adequately vaccinated population and the opposite. The results indicated that medical expenditures for a pandemic influenza outbreak could reach 83.2 billion €2017 in the no vaccination scenario and 67.3 billion €2017 in the vaccination scenario. Notably, for indirect cost estimations, vaccination in a pandemic scenario would reduce workday losses by 22.2 million days, when compared with no vaccination.

Silva et al focused on an influenza outbreak in France between 2010 and 2011 and extrapolated the results to the entire country with a hypothetical approximate number of 2 million influenza cases (3.2% of the French population), for which they calculated an overall cost of 151 million €2017 for the French Health Insurance System. Direct costs per patient ranged between 35.26 €2017 and 73.91 €2017, with higher indirect costs of 97.88 €2017 per
day due to absence from work, for those within the 15–65 age group.

Two studies assessed the cost of an influenza outbreak from an intensive care unit (ICU) and hospital perspective. One focused on ICU and hospital costs derived from an influenza pandemic in 2009 in New Zealand (among 1224 cases, of which 122 were admitted to ICUs), which surpassed 40.8 million €\textsuperscript{2017} at an average cost of 32 167 €\textsuperscript{2017} per patient, with significantly increased costs for patients with underlying comorbidities.\textsuperscript{21} The mean total hospitalisation cost (normal and ICU) per case surpassed 33 353 €\textsuperscript{2017}. Similarly, in a study that included 762 H1N1 cases from both Australia and New Zealand, the mean cost per ICU patient was 61 368 €\textsuperscript{2017}, with a per-day cost of 4767 €\textsuperscript{2017}. On the contrary, the non-ICU patient had a mean cost of 10 755 €\textsuperscript{2017}; however, overall
non-ICU patient costs surpassed those of ICU patients (12.96 million €2017 vs 6.1 million €2017), leading to a total hospitalisation cost of 19.3 million €2017 for the 2009 influenza outbreak.

Similarly, Rodríguez-Rieiro et al22 studied the hospitalisation costs that occurred during the 2009 influenza pandemic in Spain, which reached 36.7 million €2017 for 11 449 hospitalisations—during which the appearance of comorbidities led to higher average costs per patient (2205 €2017 vs 1172 €2017, respectively). Specific populations in Spain were assessed by Morales-Suárez-Varela et al23 who estimated direct costs for medical visits, medication and diagnostic tests at €3908 €2017 for non-pregnant women and 2227 €2017 for pregnant women of reproductive age, with indirect costs estimated at 107 €2017 and 64 €2017, respectively.

Cost-effectiveness studies of measures in averting and/or responding to infectious respiratory disease outbreaks
We identified 11 studies22–35 referring to preparedness, preventive and response measures, to influenza outbreaks, presented in detail in online supplemental appendix 6. Two studies were observational (based in the Netherlands and the UK),23 24 and the remaining nine were simulation models (four US models, with one study each modelled for Canada, France, Australia, Israel and one referring to developed countries in general). All included studies either used a cost-effectiveness or a cost-utility economic evaluation approach. The studies’ timeframes ranged from 2004 to 2018. Regarding the perspective for direct and indirect costs, a healthcare system or society approach was consistently presented.

The preparedness, preventive and response measures described included three pharmaceutical interventions (vaccination as a response measure, general vaccination, antiviral drug therapy and stockpiling),31–33 four non-pharmaceutical interventions (screening at the point of contact, community contact reduction, volunteer isolation/quarantine, school closure and the use of personal protective measures)23–26 28 and four combined pharmaceutical and non-pharmaceutical interventions.26 27 29 30 Table 2 presents the details of the cost-effectiveness studies on preparedness and response measures for infectious respiratory disease outbreaks. Further details on the comparative analysis of health indexes gained when advertising or responding to respiratory outbreaks can be found in online supplemental appendix 7.

With regard to studies that compared multiple interventions, a simulation model of pandemic influenza in the USA studied the cost-effectiveness of stockpile strategy and concluded that expanded adjuvanted vaccination seemed to be the most cost-effective strategy, averting 68% of infections and deaths and gaining 404 303 QALYs at $10 844 (€9600 €2017) per QALY gained relative to the stockpiling strategy.30 Saunders-Hastings et al.26 using a simulated population of 1.2 million people (reflective of Ottawa, Canada), performed a cost-effectiveness analysis of six interventions including vaccination, school closure, antiviral prophylaxis and other measures. The authors concluded that vaccination was the most cost-effective intervention when compared with other interventions while the least cost-effective intervention was school closure in conjunction with community-contact reduction, personal protective measures, voluntary isolation and quarantine. In particular, the cost per life-year saved was estimated to be $2581 (1700 €2017) for combined vaccination and antiviral treatment, while an estimated cost of $260 472/life-year saved (€171 590 €2017) was noted for school closure in conjunction with other interventions. Finally, Halder et al.27 aimed to evaluate the most cost-effective strategies suitable for a future pandemic with H1N1 2009 characteristics in Australia. The results showed that the strategy with the lowest cost was the dual strategy of individual school closure for 2 weeks along with antiviral drug strategies, with a total cost of approximately AU$632 (376.31 €2017) per case averted. The strategy with the highest cost was the dual strategy of school closure along with the continuous—50% workplace closure, with a cost of $103 million (61.3 million €2017), per 100 000 population.

Comparative cost-effectiveness analysis
A DRM approach is presented in figure 2. These interventions include both pharmaceutical measures and non-pharmaceutical measures. The interventions were compared with the ‘no intervention’ scenario, with the exception of one study29 in which the comparators were vaccination versus self-isolation, which was subsequently excluded from the DRM.

Pharmaceutical measures
Vaccination as a response measure
With the application of our inclusion and exclusion criteria, four studies assessed vaccination as a response measure in the context of an outbreak and included a cost analysis. Overall, as highlighted in the majority of the studies, vaccination as a response measure was noted to have a more significant clinical effect than comparators and was more cost-saving in most cases. According to Sander et al.,30 the most clinically effective intervention was expanded adjuvant vaccination which contributed to 404 030 QALYs. Similarly, Khazeni calculated that with expanded adjuvanted vaccination, 45 941 deaths would be averted.31 Additionally, Saunders-Hastings and et al.26 concluded that the most cost-effective approach for controlling a pandemic was vaccination in combination with antiviral therapy and prophylaxis. However, a review of the results showed that much of the cost-effectiveness of pharmaceutical interventions were driven by vigorous vaccination campaigns, while the contribution of antiviral drugs’ was not of significance. Finally, Madema et al.28 through a simulation model of an influenza pandemic among developing countries calculated the costs and assessed the effectiveness of two types of vaccines, an egg-based and a cell culture-based, in

comparison with no intervention. Overall, vaccination was more cost-effective than no intervention; however, vaccination with cell culture-based vaccines was the most cost-effective strategy with a cost of 3779 €\textsuperscript{2017} per life-year gained. General vaccination was also assessed by Sander \textit{et al},\textsuperscript{30} who noted it to be both more cost-saving and effective than the unmitigated pandemic scenario, although when comparing prevaccination with low-efficacy vaccines with full targeted antiviral prophylaxis, it was less effective and more costly.

**Antiviral drugs**

Antiviral drug strategies were assessed in five studies, where it was noted that they were both more effective and cost-saving than the no intervention scenario, primarily when used as targeted prophylaxis. According to Halder \textit{et al},\textsuperscript{27} antiviral drug strategies such as antiviral treatment and antiviral treatment in combination with household confinement and extended prophylaxis can result in reduced attack rates of 7.6% and 3.5% in comparison to the unmitigated attack rate of 13%. The costs of these strategies are also lower than the cost of no intervention.

Moreover, therapeutic treatment and postexposure prophylaxis for exposed individuals (targeted prophylaxis) were shown to be the most cost-saving.\textsuperscript{32} Consistent with the above, antiviral therapy in combination with a layered non-pharmaceutical approach seemed to reduce the overall economic costs the most and was identified as more effective when compared with no intervention.\textsuperscript{30} Furthermore, it was noted that expanded antiviral prophylaxis could help delay a pandemic when additional strategies are implemented.
and would also lead to averting 32,745 deaths in the USA.\textsuperscript{31} Finally, Sander \textit{et al}\textsuperscript{30} used a stochastic simulation model of pandemic influenza in the USA, aiming to evaluate the potential economic impact of 16 different mitigation interventions from a societal perspective. Conclusively, targeted antiviral prophylaxis was both the most cost-saving and effective intervention with a cost of $127 per capita ($118.73 \text{(2017)})\textsuperscript{20}, with the scenario of implementation of expanded antiviral prophylaxis leading to a total of 282,329 QALYs gained.

**Stockpile strategy**

The stockpile strategy was assessed in three of the studies included in this systematic review. Based on the findings, stockpiling antiviral prophylaxis in the context of a pandemic was noted to be both cost-saving for the society and averting life compared with no intervention.\textsuperscript{30} Moreover, prepandemic stockpiling of antiviral drugs would be more effective and cost-saving than no intervention if antiviral drugs were administered either solely as a treatment or as short-term prophylaxis for exposed individuals.\textsuperscript{32} Finally, stockpiling was also found more effective than a no intervention scenario (averting 29,761 deaths in the USA), although when compared with other interventions, expanded vaccination and prophylaxis were found to be more effective.\textsuperscript{31}

**Non-pharmaceutical measures**

**Pre hospitalisation screening**

Lankelma \textit{et al}\textsuperscript{23} assessed the cost-effectiveness of screening patients with acute respiratory tract infection for influenza before hospital admission. Overall costs of screening were estimated at 98,968 €\textsuperscript{2017} for 15,463 tests and 624 cases and reported net savings of 388,317 €\textsuperscript{2017} for the healthcare system. Point-of-care testing for influenza before hospital admission was identified as a cost-effective intervention.\textsuperscript{23}

**Community contact reduction**

Community contact reduction was assessed in two studies, where it was either implemented solely or in combination with other pharmaceutical and non-pharmaceutical measures. Home confinement was noted as cost-effective as a preventive measure in the context of influenza epidemics, if the proportion of compliance is adequate and infected individuals ask for medical assistance, regardless of the severity level of the pandemic.\textsuperscript{28} Isolation of infected individuals was found to be among the most effective interventions, whereas combined with community contact reduction, personal protective measures and antiviral treatment, self-isolation had the lowest cost.\textsuperscript{27}

**School closure**

The effectiveness and the economic burden of school closure were evaluated in four studies, highlighting that the duration of school closure and potentially combined strategies significantly affect its impact. Sadique \textit{et al}\textsuperscript{34} estimated the economic burden of school closure in the UK from a societal perspective and showed that the estimated costs of school closure were high, at 0.28–1.68 billion €\textsuperscript{2017} per week and the authors concluded that school closure was likely to significantly add an extra economic burden on the health system through staff absenteeism, even if school closure may delay infectious disease transmission. Similarly, Sander \textit{et al},\textsuperscript{30} who studied school closure as an additional intervention to full targeted antiviral prophylaxis or prevaccination found that while school closure further improves health outcomes (gaining 51 QALYs), it was the least cost-effective measure as it increased the total cost to society by €2700 per capita (€2524 \textsuperscript{2017}). Additionally, school closure produced only a small reduction in attack rate, whether implemented in combination with other interventions or alone.\textsuperscript{26} Finally, exclusive school closure for 2 weeks along with the continuous 50% workplace closure, antiviral treatment, household antiviral prophylaxis and extended antiviral prophylaxis, had the lowest illness attack rate (2.4%) and one of the lowest costs. On the contrary, school closure as a sole intervention to counterbalance infectious respiratory diseases was not a cost-effective measure.\textsuperscript{27}

**Personal protective measures**

Personal protective measures such as face masks and hand hygiene were assessed in two of the included studies, noting that they could contribute to the control of a pandemic, dependant though on the exposed and susceptible individuals’ compliance rate, the setting and the overall burden of the respiratory pandemic.\textsuperscript{26} \textsuperscript{28} Tracht \textit{et al} aimed to assess the cost-effectiveness of facemasks (N95 grade) in reducing the spread of pandemic (H1N1) 2009, using a simulation model of the US population and identified an economic burden of 728.28 billion €\textsuperscript{2017} (incl. direct and indirect costs). Notably, if masks are worn by 10% and 50% of the adult population of the US the net savings were calculated at 418.75 billion €\textsuperscript{2017} and 501.9 billion €\textsuperscript{2017}, respectively. Hence, the use of face masks were identified as a cost-effective preventive measure depending on the population’s level of compliance.

**DISCUSSION**

The aim of this systematic literature review of econometric analysis studies was to assess the economics of preparedness when contrasted with the cost of infectious respiratory disease outbreaks primarily within the context of European and OECD countries (excluding Japan and South Korea). Overall, the economic burden of infectious disease outbreaks is costly to healthcare systems, or to governments and society reflecting the medical costs for response activities including both the treatment of the confirmed cases and the surveillance...
and elimination of the disease’s transmission, as well as indirect costs which were also substantial.

In general, the majority of direct costs seemed to primarily reflect cost of additional personnel hours, which are mandatory for the management of the infected cases, for the organisation of response planning and contact tracing, for providing educational training and materials as well as laboratory costs. With regard to indirect costs, these could in many cases be greater than the direct costs, especially when school closures and/or workplace closures are enacted across a population, which in turn impact productivity and increase the economic burden.

While all the identified pharmaceutical and non-pharmaceutical interventions lead to a health benefit for the individual or the society, the cost benefit of such interventions differs. With regard to the potential non-pharmaceutical strategies, we identified that the use of personal protective measures, such as a facemask, is both cost-saving and effective, as also is prehospitalisation screening among suspect cases. On the other hand, all studies that assessed the impact of school closure noted that although it is an effective measure in reducing transmission, it is not cost-saving as it leads to increased economic burden. Moreover, when school closure was used as a sole intervention, then the use of limited duration school closure was significantly more cost-effective compared with continuous school closure. Community contact reduction was identified to have a positive health impact but had ambiguous results with regard to its potential cost saving as one study noted that it is a cost-saving intervention, while the other noted that social distancing strategies, such as reduced workplace attendance, were not a cost-saving measure primarily due to productivity losses, especially during longer periods of closure. Productivity losses primarily were noted to arise from pandemic related deaths and illness coupled with those losses due to interventions such as workplace closure and child-care of an ill child. It is important to note that non-pharmaceutical strategies were mostly applied complementary with a pharmaceutical measure or in combination with other non-pharmaceutical strategies in order to enhance their effectiveness. However, their cost-effectiveness highly depended on the duration, the level of compliance from the population and the type and burden of the infectious disease. It should moreover be noted that cost-effectiveness of measures will vary depending on the epidemiology of the disease in question.

With regard to pharmaceutical interventions, vaccination as a rapid response measure for infected and suspected individuals was noted to have a more significant clinical effect than comparators and was more cost-saving in most cases. As for antiviral treatment, the majority of the findings noted that it is a cost-effective strategy, especially when combined with other pharmaceutical and non-pharmaceutical interventions or when used as targeted prophylaxis for exposed individuals. Targeted antiviral prophylaxis was the most cost-saving and effective intervention, while stock-piling was cost saving in most cases and averted loss of life when compared with no intervention.

The current number of economic evaluation or cost-effectiveness studies of influenza outbreak preparedness measures is small, with an increase shown since the 2009 influenza pandemic; however, it is important to note that these studies refer to the evidence published before the COVID-19 pandemic. There are only a limited number of related reviews, however of different scope focusing primarily on policy recommendations or used dynamic transmission models in the included economic assessments of pandemic influenza preparedness measures based on significantly older studies. Additionally, most of the existing review studies either evaluate the overall economic burden of the disease or the cost-effectiveness of different pharmaceutical and non-pharmaceutical interventions without necessarily them reflecting the economics of outbreaks of infectious respiratory diseases.

Placing the above into context and following the assessment of the methodological approaches used across studies, it is essential to note the minimum contents that economic outbreaks of respiratory studies should include to help inform future and upcoming research, especially in light of the COVID-19 pandemic. These include clearly noting of the study year, the population at risk and, the population infected, the type of economic perspective (ie, healthcare, societal, etc), the study timeframe and discounting, as well as detailed reporting of the direct and indirect costs of the respiratory outcome and the interventions applied.

**Strengths and limitations**

A significant strength of this review is the comprehensive approach that was followed and the assessment of data quality—which indicated that the majority of the studies included were of high quality. Second, the synthesis of the results was performed using the DRM approach, which allowed for a direct comparison of the cost-effectiveness of each intervention to the null intervention. However, there are a few limitations: first, costs and resources varied between different countries, different regional settings and over time, making the cost component comparison of cost-effectiveness measures complex to interpret. Moreover, we only focused on EU and OECD analogous high-income countries excluding Japan and South Korea, and hence our cost-effectiveness analyses are not applicable and generalisable to other countries and particularly middle-income and low-income countries. Additionally, discrepancies in context and populations likely affect the implementation and efficacy of interventions, undermining even the effectiveness elements comparability in the cost-effectiveness measures,
especially in complex multi-component public health interventions. In addition, our study did not include studies published before 2003 or after 2019. Also, it should be noticed that publication bias may exist due to the English language restriction applied. Another limitation to be noted is that this review excluded seasonal influenza outbreaks since these occur on a yearly basis. Furthermore, this study was performed before the impact of COVID-19 and hence reflects the published knowledge before the current pandemic. Thus, the results cannot be directly extrapolated to the COVID-19 pandemic.

CONCLUSION

The value of this systematic review of econometric studies is to provide a synthesis of the evidence of the cost of respiratory infectious disease outbreaks and the cost-effectiveness of specific interventions that can be applied in response. Furthermore, our assessment identifies a minimum number of econometric measures which should be recorded during the reporting of respiratory infectious disease outbreaks that would aid future decision making. Our cost analysis results give evidence to public health policymakers, primarily in the EU or the USA, as to the cost-effectiveness of a range of pharmaceutical and non-pharmaceutical intervention strategies which may be applied to mitigate or respond to infectious respiratory disease outbreaks.
