ABSTRACT

Introduction Respiratory distress syndrome is a complication of prematurity and extremely preterm infants born before 28 weeks' gestation often require endotracheal intubation and mechanical ventilation. In this high-risk population, mechanical ventilation is associated with lung injury and contributes to bronchopulmonary dysplasia. Therefore, clinicians attempt to extubate infants as quickly and use non-invasive respiratory support such as nasal continuous positive airway pressure (CPAP) to facilitate the transition. However, approximately 60% of extremely preterm infants experience 'extubation failure' and require reintubation. While CPAP pressures of 5–8 cm H₂O are commonly used, the optimal CPAP pressure is unknown, and higher pressures may be beneficial in avoiding extubation failure. Our trial is the Extubation CPAP Level Assessment Trial (ÉCLAT). The aim of this trial is to compare higher CPAP pressures 9–11 cm H₂O with a current standard pressures of 6–8 cmH₂O on extubation failure in extremely preterm infants.

Methods and analysis 200 extremely preterm infants will be recruited prior to their first extubation from mechanical ventilation to CPAP. This is a parallel group randomised controlled trial. Infants will be randomised to one of two set CPAP pressures: CPAP 10 cmH₂O (intervention) or CPAP 7 cmH₂O (control). The primary outcome will be extubation failure (reintubation) within 7 days. Statistical analysis will follow standard methods for randomised trials on an intention to treat basis. For the primary outcome, this will be by intention to treat, adjusted for the prerandomisation strata (GA and centre). We will use the appropriate parametric and non-parametric statistical tests.

Ethics and dissemination Ethics approval has been granted by the Monash Health Human Research Ethics Committees. Amendments to the trial protocol will be submitted for approval. The findings of this study will be written into a clinical trial report manuscript and disseminated via peer-reviewed journals (on-line or in press) and presented at national and international conferences.

Trial registration number

INTRODUCTION

Respiratory distress syndrome (RDS) is common in preterm infants, and almost

Strengths and limitations of this study

- This study is a multicentre randomised controlled trial.
- This study is the largest trial comparing continuous positive airway pressure (CPAP) pressure ranges to reduce extubation failure in extremely preterm infants.
- CPAP pressures as high as 9–11 cm H₂O are yet to be formally evaluated in extremely preterm infants.
- Due to the nature of the interventions blinding of patients and clinicians are unable to occur.

universal in extremely preterm infants born <28 weeks' gestation. In this high-risk population, bronchopulmonary dysplasia (BPD), the chronic lung disease of prematurity, is a major morbidity following RDS and its treatment.¹ Many extremely preterm infants require endotracheal intubation and mechanical ventilation.¹ Mechanical ventilation, particularly if prolonged, injures the lungs and contributes to BPD.² Consequently, avoiding or minimising the time that extremely preterm infants are mechanically ventilated is critical.

The optimal way to provide respiratory support to extremely preterm infants after mechanical ventilation remains under investigation, and the transition from mechanical ventilation to non-invasive respiratory support remains a poorly understood process.² There is a paucity of data on the optimal timing of extubation, criteria for readiness for extubation, and the best strategy to use when providing post-extubation respiratory support.³ The extubation failure rate in extremely preterm infants is high,⁴ and reducing this outcome must be a focus of research.

Nasal continuous positive airway pressure (CPAP) is the most frequently used mode of

non-invasive support used after extubation of extremely preterm infants. The reasons for extubation failure during CPAP are multifactorial. Variables such as infant weight (birth weight <750g), immaturity (<26 weeks' gestation) and the severity of RDS (alveolar-arterial gradient >180mm Hg) are weakly predictive of early CPAP failure in very preterm infants.⁵ The use of a set CPAP pressure sufficient to maintain functional residual capacity is likely to be important.⁶ The optimal CPAP pressure to use after extubation is unknown, although a meta-analysis of studies suggests that pressures of at least 5 cm H₂O are needed.⁶ Many infants are reintubated following extubation for increased oxygen requirement and work of breathing suggesting that a low end-expiratory lung volume may contribute to extubation failure.⁵

Utilising higher CPAP pressures post-extubation may prevent alveolar collapse, improve lung function and reduce extubation failure.^{7,8} Kitsommart *et al* compared CPAP 7–9 cm water (H₂O) with CPAP 4–6 cm H₂O after extubation of infants with birth weight <1250g and demonstrated no difference in extubation failure within 72 hours.⁷ In a second trial, Buzzella *et al* randomised very preterm infants born 23–30 weeks' gestation with RDS to receive either CPAP 7–9 cm H₂O or CPAP 4–6 cm H₂O after extubation.⁸ Rates of extubation failure within 96 hours were significantly lower in the group randomised to the higher range of CPAP pressures.⁸ Current CPAP pressure recommendations are wide and varied.⁶ Most clinicians report pressures of 5–8 cm H₂O, however, use of CPAP pressures up to 12 cm H₂O have been reported and have not been associated with adverse effects.⁹

In extremely preterm infants, extubation failure is associated with significant morbidities, including BPD, pulmonary vascular disease, airway trauma, poor feeding and oral aversion, adverse neurodevelopmental outcomes and delayed family unit bonding.¹⁰ Thus, improving rates of successful extubation in this high-risk population of preterm infants is a clinical priority.^{10–14} The ÉCLAT trial will investigate the CPAP pressure range of 6–8 cm H₂O, routinely used in our clinical practice, with a higher-pressure range of 9–11 cm H₂O. We hypothesise that the higher-pressure range will result in less atelectatic pulmonary failure and extubation failure.

Methods and analysis

Study design and aim

We used the Standard Protocol Items: Recommendations for Interventional Trials checklist when writing our report.¹⁵ This is a multicentre, unblinded, randomised controlled trial. The aim of the ÉCLAT study is to determine, in extremely preterm infants born <28 weeks' gestation who are undergoing their first extubation, whether extubation to a higher CPAP pressure (10 cm H₂O, range 9–11 cm H₂O), compared with a standard CPAP pressure (7 cm H₂O, range 6–8 cm H₂O) decreases extubation failure within 7 days.

Sample size

The rates of extubation failure within 7 days in extremely preterm infants at the participating centres is estimated at 55%. To detect a reduction in extubation failure from 55% to 35% (absolute risk reduction 20%, relative risk reduction 40%) with 80% power and a two-tailed alpha error of 0.05, a sample size of 93 infants in each arm (total 186 infants) is required.

Patient population

Infants born extremely preterm (<28 weeks' gestation) who are intubated and mechanically ventilated and being extubated for the first time are eligible for participation in the ÉCLAT trial. The timing of the extubation is determined by the clinical team caring for the infant, and there is no postnatal age limit for participation.

Inclusion criteria

Infants are eligible if they

- ▶ Were born <28 completed weeks' gestation.
- ▶ Are being extubated for the first time from mechanical ventilation to nasal CPAP.
- ▶ Have received enteral or intravenous caffeine (as prophylaxis for apnoea of prematurity) <24 hours prior to the planned extubation.
- ▶ Have received exogenous surfactant treatment.

Exclusion criteria

Infants are excluded if they

- ▶ Are being extubated to any other mode of non-invasive respiratory support other than nasal CPAP, or to no respiratory support.
- ▶ Have a major congenital anomaly or condition that might adversely affect breathing or ventilation: for example, known upper airway obstruction or major airway abnormality, or major congenital heart disease.
- ▶ Are not receiving full intensive care after extubation.

Randomisation

Enrolled infants are randomised using Research Electronic Data Capture (REDCap) electronic data capture tools,¹⁶ hosted at the Murdoch Children's Research Institute, Melbourne, Australia. REDCap is a secure, password-encrypted, web-based application designed to support data capture and randomisation for research studies. Only the infant's first extubation is randomised. Multiple births are randomised individually. Randomisation occurs after the clinical decision to extubate has been made and shortly before extubation using a computer or smartphone. Stratification is by centre and gestational age at birth (<26 weeks; ≥26 weeks).

Clinical management

Higher CPAP pressure (intervention)

Infants are extubated to a set CPAP pressure of 10 cm H₂O. While receiving CPAP, infants will remain within a set CPAP pressure range of 9 cm H₂O–11 cm H₂O for at least 24 hours, with changes within this range at the discretion of the treating team. After 24 hours, infants

Figure 1 Study procedure. CPAP, continuous positive airway pressure; ÉCLAT, Extubation CPAP Level Assessment Trial.

may have their set CPAP pressure weaned at the discretion of the treating team but must remain within a set CPAP pressure range 5 cm H₂O–11 cm H₂O for at least 7 days after extubation if receiving CPAP. Infants are reintubated if they satisfy the extubation failure criteria described below within 7 days after extubation. The fraction of inspired oxygen (FiO₂) is titrated to keep oxygen saturations (SpO₂) in the standard target ranges of the participating unit. If extubation failure occurs, management following reintubation will be at the discretion of the treating team. For subsequent extubations, clinicians will be encouraged to use the assigned set CPAP pressure range (see figure 1).

Standard CPAP pressure (control)

Infants are extubated to a set CPAP pressure of 7 cm H₂O. While receiving CPAP, infants will remain within a set CPAP pressure range of 6 cm H₂O–8 cm H₂O for at least 24 hours, with changes to the set CPAP pressure within this range at the discretion of the treating team. After 24 hours, infants may have their set CPAP pressure weaned at the discretion of the treating team but must remain within a set CPAP pressure range 5 cm H₂O–8 cm H₂O for at least 7 days after extubation if receiving CPAP. Infants are reintubated if they satisfy the extubation failure criteria described below within 7 days after extubation. The FiO₂ is titrated to keep SpO₂ in the standard target ranges of the participating unit. If extubation failure occurs, management following re-intubation will be at the discretion of the treating team. For subsequent extubations, clinicians will be encouraged to use the assigned set CPAP pressure range (see figure 1).

Device

In both groups, infants will be extubated to continuous-flow nasal CPAP, via a mechanical ventilator (either the Dräger VN500, Dräger Medical, Lübeck, Germany, or the SLE 5000, SLE, Croydon, UK) operating in CPAP mode. After 24 hours the infant may be transitioned to ‘bubble’ nasal CPAP (Fisher & Paykel bubble CPAP circuit, Fisher & Paykel Healthcare, Auckland, New Zealand) but only if receiving a CPAP ≤10 cm H₂O given the pressure limitations of the ‘bubble’ CPAP device. Nasal CPAP may be delivered via any binasal CPAP prongs or mask, according to the participating unit’s protocol. Nasal prongs should be sized as per the manufactures guidelines to the largest size to occlude the infant’s nares.

OUTCOMES

Extubation failure

The primary outcome is extubation failure within 7 days, defined as receiving the maximum CPAP level (11 cm H₂O in the intervention group; 8 cm H₂O in the control group) and having at least one of:

- ▶ FiO₂ requirement >0.20 above the pre-extubation FiO₂.
- ▶ Two or more apnoeic episodes within any 24-hour period requiring intermittent positive pressure ventilation, or six or more apnoeic events requiring stimulation in any 6-hour period.
- ▶ Respiratory acidosis with pH <7.2 and pCO₂ >60 mm Hg.
- ▶ Require urgent intubation for an acute deterioration (at clinical discretion) with the reason for reintubation documented.

Treatment failure

Should infants not be immediately reintubated and instead managed with non-invasive positive pressure ventilation or escalated to a higher CPAP pressure than their assigned range they will be documented as an extubation failure and reported as a protocol violation.

SECONDARY OUTCOMES

- ▶ Incidence of reintubation within 72 hours, and within 96 hours.
- ▶ Failure in hours after extubation.
- ▶ Reason(s) for extubation failure.
- ▶ Kaplan-Meier Survival curve between both groups.
- ▶ Death before hospital discharge.
- ▶ Duration of mechanical ventilation in days after randomisation in survivors.
- ▶ Total duration of hospitalisation in days in survivors.
- ▶ Postmenstrual age at last supplemental oxygen, and at last positive pressure ventilation (mechanical ventilation, CPAP (or variants) or nasal high-flow >2 Litres per minute) in survivors.
- ▶ Incidence of treatment with systemic postnatal corticosteroids for lung disease after randomisation.
- ▶ Incidence of new pneumothorax requiring drainage with thoracocentesis or intercostal catheter insertion after randomisation.
- ▶ Incidence of new, radiologically diagnosed pulmonary interstitial emphysema after randomisation.
- ▶ Incidence of BPD, defined as a requirement for supplemental oxygen and/or respiratory support (mechanical ventilation, CPAP (or variants) or nasal high-flow >2 Litres per minute) at 36 weeks' postmenstrual age.
- ▶ Incidence of necrotising enterocolitis Bell's stage 2 or above after randomisation.¹⁷
- ▶ Incidence of spontaneous intestinal perforation after randomisation.
- ▶ Incidence of retinopathy of prematurity requiring treatment with laser therapy or intraocular medication in one or both eyes after randomisation.
- ▶ Incidence of new diagnosis of grade 3 or 4 intraventricular haemorrhage after randomisation.

OTHER DATA

Data collected will include

- ▶ Maternal and infant demographics: maternal parity, infant sex, gestational age at birth, birth weight in grams, mode of delivery, exposure to any antenatal corticosteroids, duration of ruptured membranes prior to delivery in days, presence of histologically diagnosed chorioamnionitis.
- ▶ Postnatal age at extubation in days, last weight prior to extubation in grams, age at first intubation in hours.
- ▶ Previous dose of exogenous surfactant received in milligrams/kilogram, prior treatment for a patent ductus arteriosus (pharmacological or surgical), prior systemic postnatal corticosteroids for lung disease.

- ▶ Mechanical ventilator settings immediately prior to extubation (mode, mean airway pressure in mm Hg, FiO₂, tidal volumes (set and achieved), peak pressures (set and achieved) and end expiratory pressure.
- ▶ Blood gas analysis results within 24 hours prior to extubation (if applicable): lowest pH, highest pCO₂, lowest base excess.

DATA ANALYSIS PLAN

Statistical analysis will follow standard methods for randomised trials. For the primary outcome, the analysis will be by intention to treat and be adjusted for the prerandomisation strata (gestational age (GA) and centre). For dichotomous outcomes, including the primary outcome, the two treatment groups will be compared using risk difference with 95% CI, both overall, and within the prespecified subgroups (gestational age at birth <26 weeks, ≥26 weeks). For dichotomous secondary outcomes, analysis will be limited to the two treatment groups, using risk difference with 95% CI. For continuous outcomes, the two treatment groups will be compared using difference of means, together with 95% CI, for outcome variables which are normally distributed; for outcome variables, which are not normally distributed, the comparison will be difference of medians, with 95% CI. All comparisons (risk difference, difference of means, difference of medians) will be estimated using regression models with the randomisation strata as covariates, and with SEs adjusted to take into account the clustering due to multiple births. Reporting of findings will be done in accordance with Consolidated Standards of Reporting Trials guidelines.

Adverse events

Adverse events (AEs) are recorded within 7 days after the randomised extubation. They are recorded as part of the study design and secondary outcomes of ÉCLAT. The site investigators are responsible for recording all AEs regardless of their relationship to the intervention. The following outcome are designated as AEs:

Necrotising enterocolitis (Bell's stage III or IV).¹⁷

Intraventricular haemorrhage (grade III or IV).

Serious AEs

Serious AEs (SAEs) are recorded within 7 days after the randomised extubation. All are prespecified secondary outcomes of ÉCLAT. The investigators are responsible for recording all events regardless of their relationship to the intervention. All SAE's are reported to an independent data safety monitoring committee (DSMC) and the local ethics committee within 72 hours of the principle investigator being notified. The following outcomes are designated as SAEs:

Death.

Spontaneous intestinal perforation.

Pneumothorax.

Pulmonary interstitial emphysema.

Study oversight

The independent DMSC established for the ÉCLAT trial have their roles and responsibilities detailed in a separate DSMC Charter. The DSMC includes two independent, experienced neonatologists and a senior statistician. The terms of reference for the DSMC include performance of interim safety analyses, periodic examination of relevant emerging external evidence, monitoring of AEs, compliance with the trial protocol, and progress of recruitment. Safety analyses by the DMSC are planned after the primary outcome is known for the first 50 and 100 infants and will occur blinded to group allocation. If required, an additional safety analysis will be performed at 150 infants. No interim analyses of the primary outcome are planned.

Clinical significance

Extubation failure is common in extremely preterm infants and associated with important neonatal morbidities.¹⁸ CPAP is the most commonly used form of non-invasive ventilation used postextubation but the optimal pressure to use for this indication remains uncertain. The ÉCLAT study will reveal novel information regarding CPAP pressures in extremely preterm infants. The ÉCLAT study is the largest trial comparing and researching CPAP pressures >8cm H₂O. Results from ÉCLAT will inform clinical practice and support clinicians in understanding and optimising CPAP pressures for extremely preterm infants. Results from this study will be disseminated via peer-reviewed journals and presented at national and international scientific conferences.
