ABSTRACT

Introduction Chronic pain is highly prevalent and associated with a large burden of illness; there is a pressing need for safe, home-based, non-pharmacological, interventions. Virtual reality (VR) is a digital therapeutic known to be effective for acute pain, but its role in chronic pain is not yet fully elucidated. Here we present a protocol for the National Institute of Health (NIH) Back Pain Consortium (BACPAC) VR trial that evaluates the effectiveness of three forms of VR for patients with chronic lower back pain (cLBP), a highly prevalent form of chronic pain.

Methods and analysis The NIH BACPAC VR trial will randomise 360 patients with cLBP into one of three arms, each administered through a head-mounted display: 1) *skills-based VR*, a program incorporating principles of cognitive behavioural therapy, mindful meditation and physiological biofeedback therapy using embedded biometric sensors; 2) *distraction-based VR*, a program using 360-degree immersive videos designed to distract users from pain; and 3) *sham VR*, a non-immersive program using two-dimensional videos within a VR headset. Research participants will be monitored for 12 weeks using a combination of patient-reported outcomes administered via REDCap (Research Electronic Data Capture), wearable sensor data collected via Fitbit Charge 4 and electronic health record data. The primary outcome will be the NIH Patient-Reported Outcomes Measurement Information System (PROMIS) Pain Interference scale. Secondary outcomes will include PROMIS Anxiety, PROMIS Sleep Disturbance, opioid prescription data and Pain Catastrophizing Scale Short Form. A subgroup analysis will explore patient level predictors for VR efficacy.

Ethics and dissemination Ethics approval was obtained from the Institutional Review Board of Cedars-Sinai Health System in April 2020. The results will be disseminated in a peer-reviewed journal.

Trial registration number NCT04409353.

INTRODUCTION

More than 50 million Americans suffer from chronic pain,¹ defined as pain that persists for 6 months or longer.² Patients with chronic pain endure a multidimensional illness that in

Strengths and limitations of this study

- Whereas most virtual reality (VR) analgesia research is focused on acute pain with short time horizons, this study is focused on a prevalent form of chronic pain with a longer time horizon to test for evidence of durable benefits.
- Study includes multiple outcomes based on a conceptual framework, including a range of relevant patient reported outcomes along with opioid dosing, thus providing a multidimensional assessment of the competing VR strategies.
- Use of a sham VR offers a rigorous control against active VR interventions.
- Although VR headsets are now widely available and will also be provided for participants in this study, there may not be systematic uptake of the study interventions along race, ethnicity, age or other demographic characteristics; this could undermine generalisability of the findings.
- Because the sham VR intervention features neutral content that may not be as emotionally evocative as the active VR comparators, there may be attrition bias in the control arm.

addition to physical symptoms of pain, affects biopsychosocial health, including low energy, impaired cognitive functioning, disrupted sleep, diminished physical and mental health and diminished social functioning.^{3–9} As a result, patients with chronic pain interact with the healthcare system frequently; 20% of primary care visits are related to pain.¹⁰

Evidence-based behavioural treatments for chronic pain are largely inaccessible to most Americans, particularly those in rural communities, due to limited availability of services coupled with recent COVID-19 restrictions on therapist-delivered treatments.¹¹ There is a need to remotely deploy self-administered, evidence-based treatments that leverage cognitive behavioural therapy (CBT), long

considered the gold-standard behavioural intervention for reducing chronic pain-specific distress, anxiety and depression.¹² Several meta-analyses demonstrate that fully-contained, self-administered CBT computer programs are feasible and effective for home-based management of chronic pain.^{13–16} Moreover, these self-contained programs can overcome geographical, staffing and timing barriers of traditional video and in-person visits.

Therapeutic virtual reality (VR) has emerged as a promising evidence-based treatment modality for reducing both acute and chronic pain.^{17–25} The ubiquity of high-performance computing has reduced both the size and cost of VR devices such that portable VR units are feasible for everyday in-home use. Most VR research has assessed pain only immediately after a VR experience.^{18 21–24} Further, most studies focus on mere distraction to impact the experience of pain ('distraction-based VR'); a small minority of studies assess more complex VR modalities that teach extensible skills using CBT principles, guided meditation and biofeedback-based breathing exercises ('skills-based VR').

The primary objective of this study is to assess the efficacy immersive skills-based VR and distraction VR in decreasing pain interference compared with placebo VR among patients with chronic lower back pain (cLBP), a model chronic pain condition that is both common and costly.²⁶ The secondary objectives focus on the efficacy of VR to improve pain interference, perceptions of sleep quality and anxiety, self-reported pain catastrophising and reduce use of opioids. Tertiary objectives include studying the impact of VR on patient reported outcomes (PRO) of depression and physical function, as well as biometric variables measured with a wearable sensor. In addition to assessing PRO and biometric data, the study also aims to identify patient-level predictors for VR efficacy. Here we present the protocol as a model for conducting research on using VR to manage chronic pain.

METHODS/DESIGN

Design

This prospective, three-armed randomised controlled trial will be conducted with participants within Cedars-Sinai Health System (CSHS), an academic medical centre based in Southern California. Two different VR pain reduction programmes will be compared with a control placebo VR program among patients with cLBP. Randomisation of all 360 subjects will be performed via Research Electronic Data Capture (REDCap) (Nashville, Tennessee), 1:1:1 across the three study groups, with random block sizes ranging from 3 to 12 subjects, stratified by site, using tables generated from Stata V.16.1 (College Station, Texas). Block randomisation is implemented in order to ensure that patients are equally assigned to each treatment group and varying the block size reduces selection bias by preventing predictability of the allocation of patients. The randomisation table was created by

an independent biostatistician at CSHS. Each arm will include one-third of the total population randomised. Potential participants will be referred by physicians at the designated clinical sites or identified using the Deep 6 AI cohort building software (Pasadena, California), which uses natural language processing to search electronic health record (EHR) data for patients meeting study inclusion and exclusion criteria throughout the healthcare system. The sites of randomisation will include patient search engine recruitment (Deep 6), orthopaedic recruitment sites, rheumatology recruitment sites and pain clinic recruitment sites.

The study has been approved by the Cedars-Sinai Institutional Review Board (IRB) (STUDY00000631) and is funded by the National Institute of Health (NIH) Helping to End Addiction Long-term initiative as part of a group of studies within the NIH Back Pain Consortium (BACPAC) programme. The IRB-approved consent includes the data sharing plan provided by BACPAC. The study is registered at ClinicalTrials.gov. No post trial care is planned for this study.

Setting and sample

All aspects of this study will be conducted remotely, including the participants' use of VR therapy and Fitbit (Mountain View, California) wearable motion and sleep tracking device. Collection of all patient reported data is performed electronically via REDCap, a secure web application. While REDCap can be used to collect a wide variety of data (including 21 Code of Federal Regulations Part 11, Federal Information Security Management Act and Health Insurance Portability and Accountability Act (HIPAA)-compliant environments), it is specifically designed to support online or offline data capture for research studies and operations.

All of the following eligibility criteria must be met: age >13, lower back pain that has persisted at least 3 months and has resulted in pain on at least half the days in the past 6 months, able to provide consent, willing to comply with all study procedures, comprehend spoken and written English, has access to either a compatible android or iOS smartphone or personal laptop or desktop computer (excluding tablets) to complete surveys and has access to email. Women who are currently pregnant or planning to become pregnant are eligible.

Patients will be excluded if they: (1) have a condition that interferes with VR usage including: history of seizure, facial injury precluding safe placement of headset, significant visual impairment that impacts ability to see the VR images or hearing impairment that impacts ability to follow audio instructions; (2) participated in a previous VR clinical study; (3) have been recommended for long-term hospitalisation that would require more than a 3-week stay in the hospital; (4) underwent a surgical procedure within the previous 8 weeks; (5) have back surgery planned within the next 3 months; (6) are using a spinal cord stimulator; or (7) have lower back pain attributable to a recognisable, specific pathology, including

spinal infection, cancer, fracture or inflammatory spondylopathies, consistent with the NIH Task Force on research standards for cLBP.²⁷

Screening process

The screening process starts with either a referral from physicians at our recruitment sites or the Deep 6 AI patient cohort programme. Study brochures will be provided to all recruitment sites. The patient's EHR will be used to help screen for eligibility as follows:

- ▶ Preferred language and age will be extracted from patient summary page.
- ▶ Presence of cLBP will be extracted from physician notes and will be verified with the participant.
- ▶ Presence of exclusions will be extracted from the 'problem list' and will be verified with the participant.

Participants identified as eligible will be emailed an IRB-approved recruitment letter explaining the study and an informational study brochure; recipients may opt-out of further contact by replying to this email. Those who do not opt-out will be called by a study coordinator who will verify remaining eligibility criteria. On verification of eligibility during this initial call, the consent form will be sent via REDCap by the study coordinator.

On receipt of their signed consent form and prior to randomisation, participants will be enrolled into the *screener week* phase of the study. The screener week was designed to ascertain willingness and ability to respond to survey questionnaires delivered by email and includes a daily electronic, one-item pain intensity question that participants are required to respond to. Participant must also complete the baseline survey questionnaires during screening week. A *screen failure* is defined as a participant who completed fewer than 86 of 108 items (80%) of the survey set provided halfway through the screener week and fewer than five of the seven pain diary questions also sent that week. Those with a partial survey completion or missing two daily pain intensity items will be sent a reminder email with a link to complete the survey to remain eligible. Once the patient completes the screener week, an unblinded group of coordinators will randomise them and support them throughout the study. Two study coordinators will monitor survey completion across the three arms and provide technical support as needed throughout the active study period. Patients will also receive a telephone number and email address to contact support staff.

An unblinded research coordinator will contact participants on receiving delivery confirmation of the study devices to provide onboarding instructions. Subsequent phone calls can be made to participants from coordinators to help participants complete the study. The diagram in figure 1 provides an overview of the study. Throughout the trial, participants and care providers are blinded to the intervention and the VR programs are described as either A, B or C with general terminology that applies to all three groups such as 'nature content'. Participants will be unblinded on study completion.

Interventions and controls

On successful completion of the screener week, patients will be randomised and sent an all-in-one VR headset, the PICO G2 4k (Shenzhen, China) and a biometric wristband (Fitbit Charge 4). We will include instructions for operating both the Fitbit and the PICO G2 4k device. Any headsets that are handled by staff will be sanitised by cleaning the fabric surfaces with Virex, the plastic housing with Sani-Wipes and the glass lenses with alcohol-based lens cleaner followed by a 1-min ultraviolet light treatment using Cleanbox (Carlsbad, California). The VR device will then be mailed to the participant's preferred address, and an email will be sent to them with a FedEx tracking number and a link to YouTube videos designed to help familiarise participants with the equipment. All three interventions will include 56 modules with a defined sequence of daily sessions. Once they complete the schedule of content sequentially, participants can repeat the experiences as many times as desired. Adherence to the intervention will be monitored by self-reported use in weekly surveys. If the answer is '0 times' they are asked for a reason (for a full list of options, see online supplemental file 1 for the list of reasons).

Sleep and motion tracking data from the Fitbit Charge 4 device will be aggregated by Fitabase (San Diego, California), HIPAA compliant, IRB approved, cloud-based software that maintains secure databases and keeps data private. Participants are allowed to undergo any concomitant treatment prescribed by their provider outside of those listed in exclusion criteria. Participants are allowed to discontinue the intervention at any time.

Intervention 1: skills-based VR (EaseVRx)

All VR programs in the study were developed by AppliedVR (Los Angeles, California). The skills-based VR program, called EaseVRx, incorporates evidence-based principles of CBT, mindfulness meditation and physiologic biofeedback therapy using embedded biometric sensors. EaseVRx combines psychoeducation, pain education, breathing training, relaxation exercises and executive functioning games to provide a mind-body approach toward living better with chronic pain (see figure 2 for details). The standardised, prescriptive and reproducible 56-day programme delivers a combination of skills training and CBT-related treatments through scheduled daily virtual experiences. An earlier version of this programme was used in a recently published randomised trial comparing it to an audio control of the same programme.²⁸ Each VR experience lasts from 2 to 16 min, with an average duration of 6 min.

Intervention 2: distraction-based VR (EaseVRx-Distraction)

EaseVRx-Distraction has the same number of experiences, the same approximate duration of experiences and a user interface identical to that of EaseVRx, with a linear, prescribed sequence of experiences. The key difference is that instead of offering a variety of VR experiences including education, games and breath biofeedback,

Figure 1 Flowchart of study procedures, from patient uptake to study completion. Rectangle boxes indicate where a straightforward step occurs. Diamonds indicate where a decision step occurs. Red circles indicate whether a patient being deemed ineligible or withdrawn from the study. Blue rectangles indicate where surveys are sent. REDCap, Research Electronic Data Capture, VR, virtual reality.

EaseVRx-Distraction includes only 360-degree videos (also present in EaseVRx). Portions of this programme were used in our previous studies to reduce pain among hospitalised patients.²⁹ This removes the effect of education and skills-based training while preserving the immersive experience of 360-degree VR.

Placebo control: sham VR (EaseVRx-Sham)

EaseVRx-Sham software includes two-dimensional nature footage accompanied by emotionally neutral music, rather than the 360-degree, three-dimensional, interactive content specifically selected for effectiveness. The experience of using EaseVRx-Sham is similar to watching a large-screen television in a dark room, but it is neither interactive nor immersive. EaseVRx-Sham has the same number and duration of experiences as EaseVRx, and the functionality of the user interface used to access the experiences is the same. The user interface was modified to remove aspects that were added for therapeutic benefit. Modifications include: a solid grey background instead of a colourful one as in other two arms of the study, the same

solid grey background for the loading scene and removal of the background music.

Study outcome measures

The primary, secondary and tertiary outcomes are provided in table 1. All PROs in table 2 have cited high reliability and validity.^{30–34} All PROs will be collected biweekly throughout the study as well as at baseline; Patient-Reported Outcomes Measurement Information System Pain Interference (PROMIS-PI) will be collected weekly for the first 30 days. All measures required by NIH Task Force on research standards for cLBP minimum-required data set will be assessed at baseline and at end of study.²⁷

Four VR specific questionnaires will also be sent throughout the study. The Immersive Tendency Questionnaire³⁵ and a customised motion sickness propensity assessment³⁶ will be delivered during the screener week. The Simulator Sickness Questionnaire³⁷ will be administered at day 1 to quantify the severity of initial side effects from VR headset use along with the presence scale to

Description of Category	Screenshot
<p>Interoceptive: These modules are designed to help the user understand and perceive what is happening inside the body. Within this biofeedback platform, changes in the observed environment reflect a progressively enhanced state of relaxation.</p> <p>Education: These modules help the user understand why the VR exercises are relevant to their pain, as well as teaching specific topics often used in pain psychology, including the neurobiology of pain, the role of mood and stress in pain, pain catastrophizing, activity pacing and setting goals. The goal of these education modules is for users to develop self-management skills and strategies manage their response to pain.</p> <p>360-degree videos: These videos provide high-quality 360 videos with voiceovers, music, and sound effects that are designed to maximize user relaxation and engagement.</p> <p>Game modules: Games are designed to maximize distraction and engagement, thereby increasing the cognitive load on patients and decreasing their perception of pain.</p> <p>Dynamic breathing: These evidence-based modules provide biofeedback training designed to enhance awareness of a user's physiological response to pain and to self-regulate that response. In multiple sessions, the user receives increasingly challenging tasks to practice diaphragmatic breathing while interacting with the virtual environment. The user is also asked to slow the breath to induce physiological changes that lead to relaxation.</p>

Figure 2 Descriptions and illustrations for each of the categories of modules in the skills based VR program. The categories of modules include: interoceptive, education, 360 degree videos, games and dynamic breathing. VR, virtual reality.

Table 1 Primary, secondary and tertiary (exploratory) outcomes

Name	Time frame	Type	Source
PROMIS Pain Interference (8 item) ^{30 42}	30 days	Primary outcome	REDCap
PROMIS Pain Interference (8 item)	60 days and 90 days	Secondary outcome	REDCap
Pain Catastrophizing Scale Short Form (6 item) ³⁴	90 days	Secondary outcome	REDCap

assess how immersive and 'real' the virtual experience was perceived to be by the participant. A custom survey to assess for adverse events and the discontinuation of treatment will be sent weekly. At the end of the study, participants will also be asked if they had experienced VR prior to the screener week and if they would want to continue to use the device at the end of the study. The case report form for every measure is provided in the online supplemental material 1. A copy of the consent form is provided in online supplemental material 2.

Data collection

Demographic data (date of birth, age, sex, height, weight) will be extracted from the EHR. To assess comorbidities through the Charlson Comorbidity Index (CCI) calculation, International Classification of Diseases, Tenth Revision (ICD-10) codes will be collected from the EHR at day 1 and day 90. All prescription data will be extracted from the EHR and supplemented by data from the California database for scheduled prescriptions called the Controlled Substance Utilization Review and Evaluation System and will include opioid prescriptions from 90 days before enrolments until 90 days after completion of the study. Variables collected continuously by the wearable devices on the patients are provided below in table 2.

If subjects do not complete the surveys, they will be sent up to three reminder prompts. The complete schedule

of measurements is provided in table 3. Participants will be eligible for up to US\$225 in Amazon electronic gift cards throughout the study. After completing 80% of the first month of surveys they will be sent a US\$25 Amazon card and another US\$25 after 75% of the second month of surveys is completed. Once 80% of surveys in the third month are completed and the equipment returned, participants will be sent a US\$175 Amazon card along with recommendations for VR programs they can use after the study.

Monitoring plan

The National Institute of Arthritis and Musculoskeletal and Skin Diseases created a data safety monitoring board (DSMB) composed of seven researchers from outside institutions. No DSMB members are otherwise involved with the study. Protocol modifications will be communicated to the DSMB and the IRB. Adverse events will be assessed on day 1 and weekly throughout the study. Monthly enrolment data will be sent to an executive secretary (Navitas Life Sciences). Virtual meetings with the DSMB are held on a biannual basis. Data Safety Monitoring (DSM) reports are submitted 2 weeks before each meeting.

Statistical analysis

Analysis of primary, secondary and tertiary (exploratory) endpoints

All statistical analyses will be performed using SAS V.9.3 or higher (SAS Institute), R pack3.5.0 (R Foundation for Statistical Computing, Vienna, Austria) or Stata V.14 or higher (StataCorp LLC). Study statisticians will be blinded to study arm; data sets will be labelled 0, 1 and 2 by the unblinded research coordinators. For the primary endpoint and all secondary endpoints, both distraction VR therapy and skills-based VR therapy will be compared with sham VR therapy using a linear mixed model repeated measures (MMRM) analysis.³⁸ Repeated measures will include changes from baseline PROMIS-PI

AE, adverse event; CURES, Controlled Substance Utilization Review and Evaluation System; EMR, Electronic Medical Record; GAD-2, Generalised Anxiety Disorder 2-item; HEAL, Helping to End Addiction Long-term; ITQ, Immersive Tendency Questionnaire; NIH, National Institute of Health ; PCS-SF, Pain Catastrophizing Scale-Short Form 6; PEG, pain, enjoyment, general activity; PGIC, patient global impression of change; PHQ-2, Patient Health Questionnaire-2; PROMISE, Patient-Reported Outcomes Measurement Information System ; SAE, serious adverse event; TAPS, tobacco, alcohol, prescription medication, and other substance use; UP, unanticipated problem; VR, virtual reality .

t-score and those obtained at days 7, 15 and 21. Models will include fixed categorical effects for treatment, week, their interaction; baseline PROMIS-PI t-score will be included as a covariant. If skills-based VR and sham VR are found to differ, a third comparison will be made between skills-based VR therapy and distraction VR therapy.

For these models, we will estimate least squares means, SEs, treatment differences (in least squares means) and 95% CIs for each time period. Primary inference will rely on treatment comparison of least squares means for day 30, and a p value will be presented for this time period only. The null hypothesis there is no mean difference in the primary endpoint between the treatment groups and the sham control group. Similar analyses will be conducted for all secondary endpoints.

Efficacy and safety data-summaries and analyses will be performed by study arm using intent-to-treat (ITT). The number and percentage of patients randomised, patient population (ITT) and treatment status (completed, discontinued/withdrew) will be summarised. Reasons for discontinuation/withdrawal will be reported. An exploratory, per protocol (PP) analysis will focus on patients who use the assigned intervention on at least 50% of days during the first 30-day period. Usage meta-data on the headsets will provide the data needed for the PP definition. No formal interim analysis or interim statistical testing for treatment comparisons is planned.

If the primary or key secondary endpoint is missing in >15% of patients in either treatment group, then the pattern of baseline covariates with missing values will be examined using the method of Little³⁹ and if data are not missing completely at random, missing values will be imputed using fully conditional specification with the multivariate imputation by chained equations algorithm under the missing at random assumption.^{40 41}

Subgroup analysis

Subgroup analyses are planned for changes from baseline PROMIS-PI using linear MMRM analysis to test for treatment and subgroup interactions. Interactions significant at $p < 0.10$ will be flagged for further assessment. Generally, models will include fixed categorical effects for treatment and week and their interaction, subgroup and treatment by subgroup interaction. Descriptive statistics of observed and changes from baseline PROMIS-PI t-score will be presented by treatment and week within each subgroup.

Subgroups to be analysed:

- ▶ Dosage of VR (min/week).
- ▶ Previous experience with VR.
- ▶ Immersive tendency questionnaire score.³⁵
- ▶ Presence score.
- ▶ Patient comorbidities (CCI).
- ▶ History of spinal surgery.
- ▶ Pain severity and duration.
- ▶ Sociodemographics (ie, age, sex, race, ethnicity, marital status, education).

Other treatments

- ▶ Tobacco, alcohol, prescription medication, and other substance use (TAPS)-1, TAPS-2.
- ▶ Mood disturbances (eg, current depressive disorder or not, severely depressed mood vs non-depressed)
- ▶ Radicular versus non-radicular back pain.
- ▶ Simulator Sickness Questionnaire cut-off (score of >15).
- ▶ Treatment expectation question.
- ▶ Perception of arm of study question.
- ▶ Motion sickness propensity survey.³⁶

Sample size

The PROMIS-PI scale has a SD of 10 and a mean of 50. Using an inflated SD of 11.83 (to accommodate correlation of repeated measures within individual) we estimated power by simulating 10 000 trial replicates and testing the null hypothesis versus the alternative hypothesis. To maintain familywise error rate at 0.05, a two-sample t-test is used to compare the control arm to each treatment arm and the test is declared statistically significant if the p value of the two-sided test is less than 0.025. Under the alternative hypothesis, data from 120 patients in each of the three arms achieved 843% power to detect a clinically meaningful effect of a change in five units of the PROMIS score. Type I error rate is 0.0469 and the SD of the PROMIS scores difference is 11.83 assuming a correlation coefficient of 0.3 between baseline and 30 days PROMIS scores. With correlation of 0.2, power is 80% to detect the same difference. Any participants who withdraw or are withdrawn or discontinued on or prior to day 30 will be replaced.

Patient and public involvement

This protocol was developed in partnership with a chronic pain patient advocate. This coauthor (TN) provided input on a weekly basis during the development of protocol and will be involved in overseeing conduct of the study together with the research team. Our patient partner helped develop custom surveys and provided input on the burden surveys and interventions might have on participants. The results will be emailed to all participants at the end of the study.

Ethics and dissemination

This trial has been approved by the IRB of CSHS. All participants enrolled in the study will provide written informed consent. The results will be disseminated through peer-reviewed scientific journals. The recruiting providers and participants will be emailed the results at the end of the study. Authorship eligibility is based on significant contribution to the study and review of the manuscript. BACPAC investigators will have access to final data set.

Trial status

Participant recruitment started in September 2020 and is expected to end in September 2023. At the time of this writing in May 2021, 96 participants have been randomised.
