ABSTRACT

Objective To systematically learn lessons from the experiences of countries implementing find, test, trace, isolate, support (FTTIS) in the first wave of the COVID-19 pandemic.

Design, data sources and eligibility criteria We searched MEDLINE (PubMed), Cochrane Library, SCOPUS and JSTOR, initially between 31 May 2019 and 21 January 2021. Research articles and reviews on the use of contact tracing, testing, self-isolation and quarantine for COVID-19 management were included in the review.

Data extraction and synthesis We extracted information including study objective, design, methods, main findings and implications. These were tabulated and a narrative synthesis was undertaken given the diverse research designs, methods and implications.

Results We identified and included 118 eligible studies. We identified the core elements of an effective find, test, trace, isolate, support (FTTIS) system needed to interrupt the spread of a novel infectious disease, where treatment or vaccination was not yet available, as pertained in the initial stages of the COVID-19 pandemic. We report methods used to shorten case finding time, improve accuracy and efficiency of tests, coordinate stakeholders and actors involved in an FTTIS system, support individuals isolating and make appropriate use of digital tools.

Conclusions We identified in our systematic review the key components of an FTTIS system. These include border controls, restricted entry, inbound traveller quarantine and comprehensive case finding; repeated testing to minimise false diagnoses and pooled testing in resource-limited circumstances; extended quarantine period and the use of digital tools for contact tracing and self-isolation. Support for mental or physical health and livelihoods is needed for individuals undergoing self-isolation/quarantine. An integrated system with rolling-wave planning can best use effective FTTIS tools to respond to the fast-changing COVID-19 pandemic. Results of the review may inform countries considering implementing these measures.

Strengths and limitations of this study

- The study systematically reviews the core elements of an effective find, test, trace, isolate, support (FTTIS) system to interrupt the spread of COVID-19. Our findings can inform policy in future pandemics.
- We reported optimal strategies reported in the literature to shorten case finding time, improve both accuracy and efficiency of tests, coordinate stakeholders and actors involved in an FTTIS system, support individuals as they progress from case finding to isolation and make appropriate use of digital tools to facilitate the programme.
- The main limitation is the scarcity of quantitative studies.

INTRODUCTION

Interrupting transmission of COVID-19 has depended on rapid isolation of infected individuals. For this to happen, a complex set of co-ordinated elements must be implemented to find potential cases, either by identifying those who have symptoms or examination of individuals at risk, test to confirm the presence of infection, trace contacts, isolate those infected and their contacts¹ and support² those in isolation to reduce the risk that they will breach any restrictions.

While various elements of a find, test, trace, isolate, support (FTTIS) system have long been core elements of the public health role, COVID-19 infection has some specific characteristics, such as transmission by presymptomatic and asymptomatic individuals³ and a strong age gradient in disease severity as well as other features that remain poorly understood. Despite this uncertainty, some countries have implemented successful COVID-19 FTTIS programmes, which have achieved

coordination among relevant actors, including central and local government authorities, laboratories and the medical care system.¹ These actors are interconnected by integrated real-time information flow. However, the ways that they have created these systems have varied, largely determined by existing structures.

There are no simple solutions. Thus, digital tools were initially seen as making a major contribution to FTTIS programmes.^{1 3} Yet while the English National Health Service (NHS) contact tracing app showed positive results in a pilot study, decreasing rates of transmission,⁴ it struggled to achieve a sufficient level of uptake to be effective.⁵ Individuals, organisations or occupational groups with high COVID-19 risk need additional support to use such apps² while it can be challenging to reduce the burden of unnecessary or repeated episodes of quarantine.

The main challenges in implementing an FTTIS programme include developing a strategy that can reduce delays in finding cases and contacts,¹ ensuring the accuracy of tests,¹ establishing integrated systems,^{6 7} reducing barriers to adhering to regulations, especially isolating^{8 9} and mitigating adverse economic impacts on the livelihood of individuals affected.⁹ To inform and support the design, implementation and continuous improvement of an FTTIS system, we conducted a systematic review, structured to answer a series of key questions that arose during the initial response to the COVID-19 pandemic. These policy questions addressed the following issues: (1) infrastructure and processes needed to achieve a sampling-to-results process taking 24 hours or less, (2) adherence to isolation and local support needs, (3) real-time data management, linkage of datasets and dashboards and ownership of the data generated, (4) achieving a 'rapid response', (5) assimilation of an application (app) in light of the above, (6) overcoming the barriers to and enablers of being tested, reporting contacts and isolating as a result of being contacted.

METHODS

The systematic review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guideline. The review protocol is described as the following.

Eligible studies

Eligible studies are research articles and reviews evaluating the strategies of contact tracing, testing, self-isolation and quarantine on COVID-19 management published in English worldwide during the urgent response of the COVID-19 pandemic (May 2019 to May 2020 and June 2020 and January 2021).

Information sources and search

We searched MEDLINE (PubMed), Cochrane Library, SCOPUS and JSTOR. The search terms included 'contact tracing' or 'testing' or 'self-isolation' or 'quarantine' in the title in combination with 'COVID-19' or 'COVID-19' or 'coronavirus' in the title or text. The full-search

strategy is included in the online supplemental appendix 1 section 1, and we apply the same search criteria for all the literature databases. The initial search included material published up to 28 May 2020. Studies were limited to those in which the subjects were human. Relevant reports and literature cited in the papers identified as well as material from other sources such as the COVID-19 Response Monitor developed by the European Observatory on Health Systems and Policies were also considered.¹⁰ The initial search was subsequently updated to include material published between June 2020 and January 2021 (online supplemental appendix 1 section 2).

Study selection

In the MEDLINE search, clinical studies, clinical trials, evaluation studies, government documents, journal articles, multicentre studies, observational studies, practice guidelines, pragmatic clinical trials and technical reports were included, as were reviewed. Studies whose subject areas were in medicine or social sciences in SCOPUS, and research reports in JSTOR (excluding book chapters) were selected. We screened title, abstract and content to remove studies unrelated to elements of FTTIS or COVID-19.

Data collection process and data items

For each publication, we extracted (where appropriate) information on study design, method, results, main findings and limitations using the PICOS tool.¹¹

Summary measures and synthesis of results

Following discussion with researchers involved in the COVID-19 response in the UK (<https://www.independentsage.org/>), a list of key questions to answer was developed and answered using the literature collected. Sheng-Chia Chung, Sushila Marlow and Nicholas Tobias screened studies and extracted the data and disagreements were resolved through discussions.

Risk of bias in individual studies

As studies eligible for policy review were mostly qualitative, we managed by using the Critical Appraisal Skills Programme (CASP) tool to assess the methodological rigour of included studies¹² (CASP Qualitative Studies Checklist).¹³

Patient and public involvement

The study questions were inspired by weekly public discussions held by Independent SAGE, a scientific group for COVID-19 response in the UK (<https://www.independentsage.org/>).

RESULTS

In the initial search, we identified 50 studies from PUBMED (Medline), 43 studies from SCOPUS, 56 from JSTOR, 1 from the Cochrane library and four from additional sources. The flow diagram is set out in figure 1. From the 164 initial publications, we removed

Figure 1 Systematic review study flow diagram. FTTIS, find, test, trace, isolate, support.

30 duplicate studies, 84 items were not directly focused on COVID-19 or strategy of testing, contact tracing or isolation or not in the format of a research report (such as editorials or podcasts). We subsequently identified an additional 58 studies in the second supplementary systematic review discussing FTTIS strategies during the early phase of the COVID-19 pandemic published between June 2020 and January 2021. We, thus, included a total of 118 studies in the review (online supplemental table S1). Eligible studies had clearly stated aims and applied appropriate methods, and although none addressed all proposed study questions, they provided data relevant to an aspect in our review (online supplemental table S2). A full list of studies included in the review is listed in online supplemental appendix 1 section 3.

Overview of FTTIS

We initially review some key findings on the COVID-19 pandemic. A review by Nussbaumer-Streit B *et al* concluded that a combination of quarantine and other nonpharmaceutical interventions could significantly reduce COVID-19 incidence and mortality.¹⁴ Policy decisions should be informed by a detailed understanding of transmission dynamics. With growing evidence that so-called super-spreading events played an important role in many outbreaks,¹⁵ finding, testing and isolating those present at such events was recognised as a priority.¹⁶ This relates to work by Manchein *et al* who proposed that the growth of COVID-19 cases follows a power-law pattern

rather than an exponential one, suggesting that transmission is characterised by features of scale-free networks, fractal kinetics and small world features. The implication is that while social distancing has been important to slow the spread of COVID-19 so far, a robust testing and isolation would be necessary to facilitate economies to reopen.¹⁷ These conclusions were consistent with work from Italy stressing the importance of maintaining very strict quarantine of those affected.¹⁸ Policies must also be underpinned by high-quality population-level data, yet some countries have struggled to create well-functioning integrated systems. Inadequate testing will often underestimate the true number and growth rate of COVID-19 cases.^{19 20} This is a challenge because testing is at the heart of a comprehensive FTTIS system and the only way to make a diagnosis where symptoms are atypical or unclear or in cases that are asymptomatic or presymptomatic.²¹ For incidence, analysing surveillance data found that the high case fatality during the first 40-day COVID-19 epidemic in Italy was primarily due to insufficient testing to characterise the outbreak accurately, thus masking transmission in the community and healthcare facilities.²² In countries where FTTI interventions have been implemented subsequently, there has sometimes been a delay in their effect on disease control.²³ There are now a number of reports of how FTTIS systems have been designed and operated.²⁴

Infrastructure and procedure of a sampling-to-results process that is 24 hours or less

Countries have differed in whether they have built on existing infrastructure or created new structures to deal with the pandemic. We have identified two complementary elements in the reviewed studies, one involves increasing sampling capacity and the other scaling up laboratory capacity. The UK addressed the first of these by implementing drive-through SARS-CoV-2 testing²⁵ with patients being informed of their results within 24–36 hours. It created a separate network of new stand-alone laboratories. Lagier *et al* reported on SARS-CoV-2 reverse transcription-PCR (RT-PCR) testing of repatriated French citizens during their initial response,²⁶ with time from sample to result reduced to 3 hours by prioritising extraction of RNA from samples. Replacing the RNA extraction step by performing RT-PCR directly on heat-inactivated or lysed samples could accelerate the process further.²⁷ Point of care testing could also reduce the time to results to less than 2 hours.²⁸

Binniker has set out the steps that should be taken when scaling up activity in existing laboratories,²⁹ which has the advantage of using networks already in place, including transport and communications. Similarly, Gupta *et al* have described how laboratories in universities and clinics in India were converted into testing centres.³⁰ In Ethiopia, Abera *et al* reported using Malaria and Neglected Tropical Diseases laboratories for COVID-19 testing.³¹ Tolia *et al* described the implementation of a testing programme within a hospital emergency department.³²

Strategies to improve the testing response

The case definition of potential COVID-19 changed frequently in the initial stage of the epidemic, as knowledge of the disease evolved. In the early stage of the epidemic, test kits and laboratory capacity were in short supply in many countries.³³ An example of an early investigation is when the Dutch National Outbreak Management Team investigated a potential SARS-CoV-2 local transmission, with rapid testing of healthcare workers in an area with a suspected COVID-19 outbreak. Testing followed a national protocol and was carried out either locally or in central laboratories. Nine hospitals were asked to sample healthcare workers on Saturday, 7 March and results were due on Monday, 9 March. When the SARS-CoV-2 positive rate came back as 4.1% among 1097 tested, the local outbreak was confirmed.

Other laboratory-based strategies to improve testing efficiency include Yan *et al* suggesting placing samples in reagents containing guanidine salts, for example, TRIzol, TRIzol LS or AVL buffer, to inactivate the virus and protect RNA.³⁴ Pooled testing approaches have been advocated to increase testing capacity^{35 36} and facilitate the detection of asymptomatic cases.³⁷ Only if the pooled batch tested positive would sample contributing to the batch be tested individually.³⁸ A three-stage pooling system was reported by Eberhardt *et al* who showed that it was possible to test three and seven times as many individuals with the same

number of test kits when prevalence rates were 5% and 1%, respectively.³⁹

Several studies examined strategies to test high-risk individuals,^{40 41} concluding that it had potential if well targeted,⁴² whereas the utility of asymptomatic testing in low-prevalence setting may be low.⁴³ Targeted testing, measured by tests per confirmed case, was reported to be correlated with a greater reduction in COVID-19 fatality than population testing number (tests per million people) in The Organisation for Economic Co-operation and Development (OECD) countries and Taiwan.⁴⁴ One measure of the performance of a contact tracing and testing system is a shorter interval between the diagnosis of the index and secondary cases.^{45 46}

Minimising false test results

Inaccurate results can impede both the treatment of the patient and public health interventions to contain COVID-19 infection.⁴⁷ Testing accuracy may be influenced by sampling and testing kit performance. The gold standard for COVID-19 diagnosis remains RT-PCR-based assays with respiratory specimens, although these can give positive results due to the persistence of fragments of genetic material after the individual has ceased to be infectious.⁴⁸ Among different respiratory sampling methods, RT-PCR assays based on nasopharyngeal swabs tend to have a lower cycle threshold than oropharyngeal swabs.³⁴ Infected individuals who are initially RT-PCR negative are likely to become positive with repeated tests as the infection progresses,^{49 50} reflecting differences in the amount of virus at the site samples and viral shedding at the time of sampling.^{49–51} Sampling error can occur due to low levels of virus at the beginning or end period of shedding or inadequate sampling techniques. Thus, recommendations are to take multiple samples,^{49 51 52} while some have proposed supporting RT-PCR results with Chest CT imaging.^{48 53}

The performance of tests has improved over time. Thus, low sensitivity (30%) was reported in the RT-PCR testing kits in the early stage of the pandemic.⁵⁴ In a review by Younes *et al*, RT-PCR testing kits developed in the USA, France and Germany had a high sensitivity, at 95%, but specificity was not reported.⁴⁸ Yan *et al* have suggested that human RNase P gene could be amplified as an internal control to reduce false-negative results and template volume could be increased to improve sensitivity.³⁴ One study from March 2020 in India found no false negatives but only five in seven positive tests were confirmed.³⁰ As a consequence, all apparent positive tests were retested by the National Institute of Virology. Point of care rapid testing has obvious benefits in terms of speed of results⁵⁵ but Döhla *et al* reported that tests available in the initial period of the pandemic had low sensitivity (36.4%) compared with RT-PCR, although this was in a small group of 39 patients with COVID-19.⁵¹

Besides RT-PCR testing, serologic antibody assays detect immunoglobulin G and immunoglobulin M to SARS-CoV-2 after infection.⁵⁶ This has been used to determine

whether an individual or the proportion of a population has previously been infected.⁵⁷ Given concerns about the duration of antibodies and limitations in sampling and testing, there is a need for caution about potential false-negative results, and repeated testing may be required if symptoms persist. Testing at the end of the quarantine may help identify and care for delayed or asymptomatic COVID-19 cases while preventing further transmission.⁵⁸

In addition to the aforementioned challenge relating to false-negative results, concern has been raised about the specificity of rapid antigen assays, with the risk of a high proportion of false positives, particularly as overall population prevalence reduces. For this reason, some countries are instigating PCR confirmation of positive rapid test results.⁵⁹

Linked data to facilitate active case finding

There are several examples of how linked health service data can be used to identify cases.^{24 60} For example, the digital COVID-19 border control system in Taiwan collects the health information of inbound passengers. The data are linked to the 'epidemic prevention tracking system' used by health authorities to ensure isolation and quarantine of cases and are linked to the National Health Insurance MediCloud System, a cloud-based platform for medical professionals to gain updated clinical data of the patient seeking care.⁶¹ The data linkage provides medical staff with real-time information on the patient's COVID-19 travel and contact history, home isolation and quarantine status, to provide necessary care with appropriate infectious control measures.⁶² Screening high-risk populations (such as healthcare workers) has been used for active case finding.⁶³

Adherence to isolation and local support needs

Inbound traveller quarantine

Border controls and restricted entry were imposed in East Asian countries early in the pandemic,⁵⁴ linked to comprehensive inbound traveller quarantine. For example, Singapore imposed a 14-day 'Stay Home Notice' (SHN) on visitors and returning residents from COVID-19 endemic areas since January 2020 and for all inbound traveller from 9 April 2020. On arrival, travellers underwent a 14-day mandatory stay in government-designated hotels. During this period, they were not allowed to leave their individual rooms, where specific infectious disease prevention procedures were implemented.⁶⁴

Timely identification of contacts

Ferretti *et al* reported an estimated reproduction number of the initial SARS-CoV-2 variants of 2.0, of which 0.9 was associated with infection occurring during the presymptomatic stage, suggesting about half of the cases were infected by patients with COVID-19 before symptom onset.⁶⁵ An individual infected by SARS-CoV-2 can actively shed the virus from their respiratory system 6 days before and 3 weeks after displaying symptoms, depending on disease severity.^{34 48} While the virus detected in respiratory

samples peaked within the first week of the illness, virus shedding continues in stool samples and peaks in week 2 or 3.³⁴ It, thus, is essential to stop the transmission by rapidly finding potential cases and their contacts and quarantining.⁶⁶ One modelling study reported how minimising testing delay effectively reduced onward transmission.⁶⁷ Countries may apply an additional week of self-health management beyond the 2-week quarantine period.²⁴

Modelling studies have indicated that strategies to reduce random community contacts are preferable to those based solely on reducing personal contacts,^{40 68} the duration of quarantine can vary depending on the reduction of contacts reached by individuals⁶⁸ and testing at the beginning and the end of quarantine.⁶⁹ The definition of contact may vary; Korea applied a focused testing strategy where, when a COVID-19 outbreak with an unknown source of infection occurred, there was the testing of individuals who were working, living or visiting in the outbreak area.⁷⁰ Individuals who tested positive were hospitalised, whereas individuals who tested negative were self-quarantined for 14 days. The strategy effectively reduced the proportion of COVID-19 cases with an unknown source of infection and the risk of transmission in the community.⁷⁰ The direction of contact tracing may be forward or both forward and backward; the latter identifies unascertained or asymptomatic carriers and enables the isolation of those involved in otherwise undiscovered transmission.²⁸

Digital tools to facilitate FTIS

Conventional epidemiological contact tracing, which relies on personal interviews, is labour intensive and time-consuming and may be challenging during a large-scale epidemic.^{24 71} Some countries have applied digital tools in COVID-19 responses. Measures that use automated monitoring of geolocation data generated automatically by smartphones have advantages over voluntary tools (such as apps), but there may be differing concerns about privacy among countries.⁷²⁻⁷⁴

Types of telecommunication provider-based measures may include:

1. Mapping anonymised cell phone movement in a particular area (eg, Germany, Austria, Italy).
2. Base station triangulation to approximate cell phone location (Taiwan and Hungary)⁷⁵ or
3. Access to Global Positioning System (GPS) data generated by the phone (Israel).

Voluntary provision of data includes:

1. An app that captures proximity to other enabled mobile devices within a specified range via Bluetooth (Singapore, Austria).
2. An App recording daily symptoms (South Korea, Taiwan, Poland, UK) or
3. A Quick Response (QR) code for entry or exit to key locations (China).

Aslam *et al* reviewed the digital tools used in East Asian countries for COVID-19 response by their level of

intrusiveness.⁵⁴ Low intrusive digital tools provide services to individuals and act as the interface between authorities and service users.⁶⁰ Such tools are generally widely accepted. Other tools are used to enforce quarantine and may involve individual movement restrictions and privacy concerns.⁷⁶ These are subjected to debate and have lower acceptability, yet large-scale uptake (60%–75% of the population) may be necessary for them to be effective.⁷³ For example, in Singapore, the initial voluntary use of the contact tracing app was only 12%.⁷³ The use of such apps requires a clear legal basis for the information that can be used exclusively for infectious disease control and comes with strong legal limits on data access.^{54 74}

Support for individuals complying with self-isolation

Webster *et al* identified factors associated with adherence, which included the knowledge people had about the disease and quarantine procedures, social norms, perceived benefits of quarantine and perceived risk of the disease as well as practical issues such as access to essential supplies or the financial consequences of being out of work.⁷⁷ Self-isolation or quarantine may not be affordable for low wage and informal workers.⁷⁸ To address financial needs, the Singaporean government provides self-employed persons and businesses with employees undergoing self-isolation or quarantine (SHN) a US\$100 per day support. Deliveries of food and other supplies can be arranged for individuals in SHN, through a designated hotline. By law, landlords and dormitory operators cannot evict tenants in SHN. For individuals in residences may not be suitable for SHN, the government offers hotels as an alternative.⁶⁴

Psychological stress,^{77 79 80} cognitive dissonance⁷⁴ or lack of physical activities⁸¹ during self-isolation may adversely affect mental or physical health. While anxiety was reported to be positively associated with an interest in security-related actions, perceived restriction to personal freedom had a negative impact on taking these actions and loneliness related to nonaction.⁸² In a rapid review, Brooks *et al* reported individuals in quarantine experiencing confusion, anger and post-traumatic stress symptoms, for reasons such as fear of infection, frustration, boredom and inadequate supplies.⁷⁷ Austria and Germany reported an increase in domestic violence associated with COVID-19 restrictions.⁸³ Strategies to mitigate these adverse effects include timely and sufficient information to reduce uncertainty, minimising the quarantine period to no longer than is necessary and providing adequate supplies for individuals serving self-isolation.

Razai *et al* suggested using validated psychological screening tools, such as the UCLA Loneliness Scale and Patient Health Questionnaire-4 for anxiety and depression to identify individuals who need support. This can help identify those who may benefit from counselling, coaching via telephone or online video consultations.⁸⁰ Nonmedical social prescribing, such as visual choirs, online theatre or performances, exercise or art classes can reduce boredom. Communication using social media

may ease loneliness. Banskota *et al* reviewed smartphone apps to assist older adults in coping with self-isolation, designed for social networking, food and drinks delivery, medical consultation, health and fitness.⁸⁴ Meinert *et al* described an agile process to develop an app for older people and their families to improve well-being while observing social distancing rules.⁸⁵

How would real-time data management, linkage of data sets and dashboards be developed, and who would 'own this'?

In Austria, the nationwide online COVID-19 dashboard has facilitated effective early response to COVID-19 pandemic.⁸³ In South Korea, the government links digital databases to facilitate contact tracing, including electronic health records, phone-based GPS, card transaction records and closed circuit television.⁷² Yasaka *et al* have proposed the use of an app with three guides, requiring users to register with checkpoints (eg, public spaces or shops with a QR code that can be scanned to the app), check risk level and report COVID-19 status.⁸⁶ Likewise, in China, a QR code-based app is used to limit the movement of suspected patients with COVID-19 and displays a green, amber or red code that is required to be in or enter locations, but the digital surveillance architecture and data protection mechanisms remain unclear.^{54 73 74} Consequently, public concerns about data protection and privacy have been raised in respect to both the Chinese and South Korean apps.

The efficacy of mobile positioning data (although not possible for 2G phones) was studied in Nigeria by Ekong *et al* based on systems used in South Korea, Singapore and China.⁸⁷ A legal framework for data protection was suggested when implementing these systems and a third-party agreement was put in place for data use.

Mobile geopositioning data

Mobile geopositioning has been used to study the mobility, connectivity and health risks in travellers.⁸⁸ These have an accuracy of 150 metres, so they reduce the risk of undermining individual privacy.²⁴ Taiwan has applied a geopositioning method to facilitate adherence to home isolation or quarantine, rapidly identifying contacts in a suspected large-scale outbreak. An example is the identification of 627 386 contacts of the 3000 Diamond Princess passengers touring in Taiwan during a COVID-19 outbreak.²⁴ The process took a day and text messages advising self-health management were sent to all contacts. Contact data were linked to electronic health records for follow-up and testing of symptomatic contacts. Geopositioning data have lessened the pressure on health authorities who would otherwise have relied on resource-intensive manual contact tracing, facilitating timely large-scale outbreak containment. The resources saved by leveraging technology can then be used for taking care of vulnerable populations and those without access to a mobile phone.

How would a 'rapid response' occur and what would precipitate such a response?

On 22 January, an individual from Wuhan who had travelled to Hong Kong reported respiratory symptoms, and a second suspected case was reported the next day. Both received medical care, being placed in isolation and later testing positive for COVID-19. Contact tracing started immediately and the travel histories of patients were retrieved and published online. All their close contacts, including passengers seated close by and taxi drivers, were subjected to quarantine at a holiday village converted to a quarantine centre to host contacts of confirmed cases. A hotline was set up to answer public enquiries, especially for passengers on the same train/flight.⁸⁵

In Singapore, proactive contact tracing and cluster identification are key features of the country's COVID-19 response. Health professionals are trained to identify potential outbreak clusters, asking a series of questions to patients with COVID-19. The Ministry of Health works with hotels to develop quarantine sites and liaises with those possessing the closed-circuit television footage to track cases.⁸⁵

Infection control

Inadequate infection control during isolation or quarantine may increase the transmission of SARS-CoV-2. Close quarter isolation was found to be ineffective⁸⁹ in the case of the Diamond Princess. The virus spread to 634 passengers despite contact tracing⁹⁰ and safety measures,⁹¹ leading the authors to conclude that aerosol transmission played an important role in confined settings. However, this was questioned by Wang *et al* in a hospital study of transmission via air, sewage, surfaces and personal protective equipment in which swabs tested positive only from sewage.⁹²

Nosocomial infection

Nosocomial infection and cross infection of health workers were reported at the Sheffield Teaching Hospitals NHS Foundation Trust; of 1533 symptomatic healthcare workers, 18% were positive for SARS-CoV-2.⁹³ It was estimated that a third of staff had completed a shift while symptomatic, emphasising the need for regular and efficient testing for healthcare workers who have a high risk of infection, for the protection of vulnerable patients and civilians. A study in Taiwan on the risks of contact infection before and after symptom onset showed that the spread of COVID-19 was highest within the first 4 days of infection. In comparison with transmission to medical staff, most transmissions took place in the family or social settings, partially due to the absence of the personal protective equipment (PPE) and partially due to contact in the early stages of infection (presymptomatic).⁹⁴

To control nosocomial infection, Taiwan implemented nationwide enhanced Traffic Control Bundling (eTCB) in hospitals, whereby infection was controlled with a combination of triage prior to hospitalisation, separation between risk zones, strict PPE use and hand disinfection checkpoints.^{60 95} Risk zones were divided into the contamination, intermediate and, finally, clean. This drew on earlier research by Yen

et al in which SARS infection among healthcare workers in the eTCB hospital was 2(0.03 cases per bed) compared with 50 probable cases (0.13 cases per bed) in the control group.⁹⁶ This strategy was implemented across Taiwan on 21 May 2003 and within 2 weeks the epidemic was under control.

How would an app be assimilated in light of the above?

The Singaporean government has developed the App 'TraceTogether' to support manual contact tracing,⁹⁷ recording other users who have been in proximity to a smartphone user via Bluetooth. After a user is found to be positive, individuals at risk are contacted directly.^{54 74} The Pan-European Privacy-Preserving Proximity Tracing coalition proposed a privacy-friendly contact tracing apps with the use of matching Bluetooth signals, based on the Singaporean 'TraceTogether' app.⁷³ The Korean Ministry of the Interior and Safety has developed a mobile phone application named 'self-quarantine safety protection' app that monitors the location of the quarantined user, informs health authorities, allows the user to report on their symptoms, and health officials can evaluate if a test is needed.⁷² TRACE, the national contact tracing programme in Taiwan, developed in 2017 has an integrated system to monitor health, trace contacts and link to other databases for a range of infectious diseases. The location of individuals could be tracked and communication between the user, Taiwan Centers for Disease Control and Prevention (CDC), police and authorities as well as local health departments could be centralised through this platform for reporting symptoms and contact tracing.⁹⁸

What are the barriers to and enablers of being tested, reporting contacts and isolating as a result of being contacted?

Logistics

A lack of public health funding may weaken outbreak preparedness.⁹⁹ Regionalisation of the healthcare system might result in fragmentation of the epidemic response and timely data availability.²² Scarcity of healthcare resources creates major barriers to COVID-19 control.¹⁰⁰

Testing

With the USA in mind, Parmet *et al* encouraged the promotion of 'free testing' in order to reach poorer communities and eradicate the infection.⁷⁸ Although the UK implemented free testing for adults, there have been challenges in communicating information on how to obtain a test and in what circumstances, particularly among certain ethnic minority groups. Understanding the factors associated with testing uptake in the population may inform better testing strategies.¹⁰¹ Mark *et al* reviewed the feasibility of a mobile community testing team in Scotland and reported a lack of guidance on infection control for testing in the community, thereby risking cross-transmission. Other barriers included the shortage of staff,¹⁰² shortage of testing kits and strict testing eligibility, which excludes asymptomatic patients from receiving testing on time.⁸³

Contact tracing

Validity and reliability of information recorded by an app may not be accurate or precise due to technological limitations.⁸⁴ Klonowska *et al* summarised the high coverage needed for an app to be effective. This may be difficult to reach on a voluntary basis, for issues such as mobile storage data, operating systems and battery power to support constant Bluetooth activation, the fact that young children and senior citizens may not carry or own a personal smart device and the issue of individual willingness.⁷³ In the UK, only 47% of individuals who are 75 years or older use the internet.¹⁰³ Senior citizens in the Netherlands were also less likely to adopt a contact tracing app than their younger peers.¹⁰⁴ It is essential that outbreak control teams cater to their needs and those of community volunteers, such as the NHS volunteer responders in the UK.⁸⁰

Isolation

Logistic challenges arise in providing food, sanitation, transport¹⁰⁵ and care for individuals living in a restricted zone, especially if this covers a large area.⁷⁸

Public awareness and communication

The number of tests carried out during an emergency will depend on public perception of the reliability of testing services and the effectiveness of communication of actions that can be taken. It is also necessary to ensure that kits and the location of testing stations are accessible to disadvantaged groups who may not have access to a smartphone or basic supplies. Where ethnic minorities are at greater risk, special efforts must be made to encourage them to access tests. Regular press conferences by authorities, briefing on the progress of the pandemic, changes in policies and correcting misinformation⁶⁰ can increase public awareness of the need for FTTIS and tackle rumours that arise where there are knowledge gaps and uncertainties.⁹⁵ However, under-reporting of COVID-19 deaths by the government may occur in countries with incomplete vital registration or under political influence.^{20 106}

The internet and social media have an important influence on behaviour in isolation,¹⁰⁷ which has grown with increased internet use since the COVID-19 lockdown. Farooq *et al* tracked the effects of social media, news websites and emails as well as the living situation on the individual level, and the intention of self-isolation during the pandemic in a panel of 225 participants¹⁰⁸ and found that while frequent social media use contributed to information overload and cyberchondria, it increased propensity for self-isolation. McNeill *et al* similarly studied the effects of tweets and found that social media played a role in the motivation to conform to health measures.¹⁰⁹ Based on populational surveys, Kowalski *et al* reported that conspiracy beliefs of COVID-19 were negatively associated with adherence to self-isolation guidelines in Poland.¹¹⁰ To motivate members of the public to self-isolate in a healthy way, a combination of lowering perceived response costs and clear information about the severity of risks should be implemented.^{108 111} It is

also suggested that messages of the severity of disease be disseminated via reliable official networks such as government outreach, news and journalism, while social media focuses on hopeful messages and recommended health measures.¹¹²

Legal issues

In Singapore, the Infectious Diseases Act provides a legal basis to prosecute those who are noncompliant, with resulting fines and/or imprisonment.⁶⁴ Similarly, the Communicable Disease Control Act in Taiwan mandates the government to implement effective measures in COVID-19 controls including FTTIS.⁶⁰

In the USA, the Public Health Service Act empowers the Surgeon General (delegated to the CDC) to enforce quarantine and isolation and provide medical care for detained individuals. Court rulings establish that quarantine cannot be imposed in a way that is racially discriminatory, and governments are required to have a strong legal basis for imposed restrictions.⁷⁸

Public cooperation

The effective control of the highly contagious COVID-19 epidemic relies on collaboration by individuals to voluntarily provide their information and comply with preventive measures. In low or middle-income countries, low public trust due to government corruption impedes public cooperation to observe FTTI regulations.¹¹³ The potential undesirable outcome of telling the truth, such as adverse immigration consequences for noncitizens, deportation of undocumented migrants or refusal of entry for passengers with a fever, can be a barrier for these individuals, who may be at high risk of infection, to seek care or provide accurate information.⁷⁸ Results from a multinational survey in France, Germany, Italy, the UK and USA showed high public acceptability of a contact-tracing app.¹¹⁴ Perceived benefits, self-efficacy¹¹⁵ and trust¹¹⁶ were positively associated with contact tracing apps uptake. Special protection of personal information is needed, with the goal of facilitating trust, prioritising care and encouraging individuals to cooperate and to prevent further transmission of the disease.

Economic support

To ease the economic pressure and uncertainty during large-scale quarantine, governments have established different schemes to support individuals and families. Income compensation during quarantine has shown to double the compliance with self-isolation.¹¹⁷ East Asian countries have provided support schemes for employers, employees and households.⁵⁴ In the USA, the federal government passed the Families First Coronavirus Response Act, including paid sick leave and unemployment insurance.⁹⁶ Countries implemented funding, financial stimulus, loans, aid packages to support the economy⁸³ or individual livelihood.¹¹⁸ In the UK, national job retention schemes and financial support schemes

have been rolled out to support individuals and businesses during the COVID-19 epidemic.⁹⁶

DISCUSSION

We identified in our systematic review the core elements for an effective FTTIS system necessary to interrupt the spread of a novel infectious disease, as in the COVID-19 pandemic. The optimal strategies for a successful FTTIS during COVID-19 rapid response include:

Finding

Border controls, restricted entry and inbound traveller quarantine applied early in the pandemic have both reduced the spread of COVID-19 and facilitated case finding. Testing high-risk populations (such as health-care workers or residents of long-term care facilities) is important for active case finding, especially during the early stages.

Testing

During the initial response to a pandemic, repurposing of an existing laboratory network for testing should be implemented where possible while establishing new testing sites to meet increasing needs as the pandemic progresses. Pooled testing can be used to improve testing efficiency. Repeated testing may be necessary to minimise false-negative results.

Trace and isolate

Digital tools such as apps, GPS and mobile geopositioning data have been deployed effectively by some countries for contact tracing and to monitor compliance with self-isolation. As an individual infected by SARS-CoV-2 can actively shed the virus 3 weeks or longer after symptoms onset, the duration of quarantine may vary. A 2-week quarantine period with extension when required has been adopted by various countries.

Support

Support can be in the form of mental health or physical health promotion or monetary aid, such as timely and adequate information to reduce uncertainty and anxiety, providing adequate supplies or allowance for individuals. These support measures also facilitate public trust that is fundamental in the joint COVID-19 response in the population, as it relies on individuals to voluntarily provide their information and adhere to disease control regulations.

Integrated system

Although these measures, often combined, are implemented in different countries, the level of preparedness, timely implementation and scale-up of effective measures made the difference between¹¹⁹ or within¹²⁰ countries. For incidence, insufficient testing and quarantine led to the undetected wide transmission of SARS-CoV-2, resulting in high case fatality during the first month of COVID-19

epidemic in Italy²² and similarly in the Middle East²⁰ or during the first wave in the UK.¹²¹

A successful FTTIS requires seamless integration of all the components and the ability to integrate vulnerable populations or ethnic minorities. Linked health service data can contribute to the cooperation and communications among responsible authorities (central and local government, borders, laboratories and the medical care system) through real-time data sharing and dashboards.

Public collaboration

In addition to support for individuals, regular press conferences by the central outbreak control team to provide a briefing on the progress of the pandemic, changes in policies and correcting misinformation can increase public awareness of the need for FTTIS. Open and balanced discussions on public concerns, such as personal data privacy and protection and limitations on individuals' freedom for the public good, are essential.

Agile process

The uncertainty and rapid progression of the pandemic make it important to have the flexibility to adapt rapidly to emerging challenges. A rolling-wave approach to planning can help authorities learn, apply and refine tools for prevention and control, with an agile process allowing better responses to emergencies.

Strengths

We found no published systematic review addressing simultaneously the finding, test, tracing, isolation and support in the early response of COVID-19. Results of our review thus may inform countries facing future pandemics.

Limitations

We reviewed studies published in English, thus enable the review team to cross-validate the results. Although information documented in other languages might be missed, our search included studies from all regions of the world. Our review focused on FTTIS in the early phase of the pandemic. However, going forward, it will be important to draw on lessons learnt later in the pandemic.

Conclusion

This comprehensive systematic review identified effective strategies for a successful FTTIS system to interrupt the spread of a novel infectious disease. These include border controls, restricted entry, inbound traveller quarantine and screening for case finding; repeated testing to minimise false diagnoses and pooled testing in resource-limited circumstances; extended quarantine period and the use of digital tools for contact tracing and self-isolation. Support for mental or physical health and livelihood is needed for individuals undergoing self-isolation/quarantine. An integrated system with rolling-wave planning can best use effective FTTIS tools to respond to the fast-changing COVID-19 pandemic. Results of the review

may inform countries considering implementing these measures.
