SUpporting wellbeing through PEeR-Befriending (SUPERB) feasibility trial: fidelity of peer-befriending for people with aphasia

Nicholas Behn 1, Becky Moss 1, Sally McVicker 1, Abi Roper 1, Sarah Northcott 1, Jane Marshall 1, Shirley Thomas 2, Alan Simpson 3, Chris Flood 4, Kirsty James 5, Kimberley Goldsmith 5, Katerina Hilari 1

ABSTRACT

Objective To evaluate systematically the fidelity of a peer-befriending intervention for people with aphasia.

Design SUpporting wellbeing through Peer-befriending (SUPERB) was a feasibility randomised controlled trial comparing usual care to usual care + peer-befriending. This paper reports on the fidelity of all intervention aspects (training and supervision of providers/befrienders; intervention visits) which was evaluated across all areas of the Behaviour Change Consortium framework.

Setting Community.

Participants People with aphasia early poststroke and low levels of distress, randomised to the intervention arm of the trial (n=28); 10 peer-befrienders at least 1-year poststroke.

Intervention Peer-befrienders were trained (4–6 hours); and received regular supervision (monthly group while actively befriending, and one-to-one as and when needed) in order to provide six 1-hour peer-befriending visits over 3 months.

Main measures Metrics included number and length of training, supervision sessions and visits. All training and supervision sessions and one (of six) visits per pair were rated against fidelity checklists and evaluated for inter-rater and intrarater reliability (Gwets AC1 agreement coefficient). Per-cent adherence to protocol was evaluated.

Results All peer-befrienders received 4–6 hours training over 2–3 days as intended. There were 25 group supervision sessions with a median number attended of 14 (IQR=8–18). Twenty-six participants agreed (92.8%) to the intervention and 21 (80.8%) received all six visits (median visit length 60 min). Adherence was high for training (91.7%–100%) and supervision (83%–100%) and moderate-to-high for befriending visits (66.7%–100%). Where calculable, inter-rater and intrarater reliability was high for training and supervision (Gwets AC1 >0.90) and moderate-to-high for intervention visits (Gwets AC1 0.44–1.0).

Conclusion Planning of fidelity processes at the outset of the trial and monitoring throughout was feasible and ensured good-to-high fidelity for this peer-befriending intervention. The results permit confidence in other findings from the SUPERB trial.

Trial registration number NCT02947776.

INTRODUCTION

In stroke rehabilitation research, evaluation of fidelity is a core recommendation and an integral component of intervention trial design. Fidelity refers to the ‘methodological strategies used to monitor and enhance the reliability and validity of behavioural interventions’ (p.443) and is needed to ensure that an intervention is delivered as intended.

Assessing fidelity can assist researchers to identify the essential elements that help to make a treatment work. Fidelity can also help explain nonsignificant or ambiguous findings6 as the lack of an effect may be due to poor implementation of a treatment or problems with the treatment itself. Fidelity is essential in making decisions about an
intervention’s efficacy and replication. The treatment Fidelity Workgroup of the National Institutes of Health Behaviour Change Consortium reviewed existing definitions and practices of treatment fidelity and developed recommendations for consistent reporting across five key areas: study design, training providers, delivery of treatment, receipt of treatment and enactment of treatment skills. Over the years, this workgroup has further described and refined methods for the assessment, monitoring and enhancement of fidelity.9,10

Despite its importance, fidelity is rarely reported in stroke and aphasia studies. In a review of stroke rehabilitation trials published in 2015 (n=182 papers), fidelity was reported in less than 10% of the studies. In a review of 149 aphasia intervention studies (2002–2011), fidelity was reported in 14% of studies.11 In a more recent review of aphasia randomised controlled trials (RCTs) (2012–2017), 21% of studies explicitly reported fidelity.12 Similarly, fidelity is rarely reported in befriending studies. In 34 intervention studies across two systematic reviews, only six studies (18%) referred to fidelity. Peer-befriending is an intervention where social and emotional support is provided by people with experience of a condition to others sharing a similar condition to bring about change.15 Peer-befriending fits within the stepped care model for offering psychological care, which offers simpler interventions first (level 1) before progressing to more complex interventions. Peer-befriending may be beneficial for people with aphasia post-stroke with no or low mood problems. It may avert some long-term psychological consequences such as depression and reduce the need for more costly psychological therapies. The Supporting wellbeing through PEer-Befriending (SUPERB) study is a feasibility RCT of peer-befriending for people with aphasia poststroke with low levels of psychological distress. Peer-befriending is a complex intervention requiring active engagement of both the provider and recipient of treatment, with scope for low compliance. Therefore, a comprehensive assessment of fidelity was prespecified and built into the protocol, to monitor the intervention and help interpret the trial results.

The aim of this study was to systematically evaluate fidelity within the SUPERB trial. We describe the development, assessment and monitoring of fidelity strategies and report on the fidelity of all aspects of the intervention, including training and supervision of providers.

**METHODS**

The SUPERB trial was a single-blind, parallel-group feasibility RCT comparing usual care to usual care + peer-befriending; full methods are reported elsewhere.18 SUPERB was funded by the Stroke Association and sponsored by City, University of London. Recruitment commenced in April 2017; data collection was completed in August 2019. This paper focuses on the methods related to checking and reporting of fidelity (table 1). Fidelity strategies were developed, assessed and monitored across all five areas proposed by Bellg et al: study design, training providers, delivery of treatment, treatment receipt and treatment enactment.2

**Patient and public involvement**

People with aphasia were engaged at every stage of the SUPERB trial, with full details reported in the protocol paper.18 At the proposal stage, a group with experience of befriending from the organisation Aphasia Re-Connect (n=6) influenced our plans, including, the nature and timing of intervention and the use of mixed methods (quantitative and qualitative). At the development phase of the trial, another group of six consultants with aphasia participated in a series of workshops and advised on aspects, such as trial materials including) intervention manuals, outcome measures and selection and matching of peer-befrienders. They also contributed to the development of fidelity checklists. During and after the trial, a user group comprising five people with aphasia and one significant other advised on management issues, helped us explore the implications of the findings, and informed our dissemination to the stroke community (regular trial newsletters, social media promotion, website, videos after the trial).

**Participants**

Fifty-six participants were recruited and randomised to either usual care (n=28) or usual care + peer-befriending (n=28), soon after discharge from hospital and when active care was withdrawn. Participant characteristics are reported in detail elsewhere. The sample in this report are those in the intervention arm: their mean age was 70.5 years; the majority were white (53.6%), retired (67.9%) with a fairly even split between male (53.6%) and female (46.4%). Most of the group had suffered an ischaemia stroke (82.1%), and left hemisphere stroke (96.4%). Participants were a median (IQR) 48 (21.5–86.5) days poststroke. Aphasia severity ranged from mild (64%), moderate (11%), to severe and very severe (25%), based on the Western Aphasia Battery-Revised. Cognition ranged from within normal limits (18%) to mild (32%), moderate (25%) and severe (25%) cognitive impairment (Cognitive Linguistic Quick Test).2 Peer-befrienders were people with mild-moderate aphasia, ≥1 year post-stroke, nominated by community services and screened by the trial manager. Ten befrienders were recruited, trained and delivered the befriending intervention. Their mean age was 54.2 years; the majority were female (80%), white (60%) and in volunteer work (50%). Most befrienders had suffered an ischaemic stroke (60%) in the left hemisphere (70%). All befrienders had mild-to-moderate aphasia based on the Frenchay Aphasia Screening Test.22

**Intervention**

Full details are provided in the SUPERB protocol paper.18 Befrienders attended training and participated in...
## Table 1  Fidelity strategies for the SUPERB trial

<th>Study design</th>
<th>Metrics and criteria (primary metrics in bold)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ensure same treatment dose within conditions</td>
<td>► Feasibility RCT. Theoretical model for intervention identified and active ingredients operationalised in a treatment manual and befriender handbook to ensure consistency of training. ► Befrienders trained in 4–6 hours over 2–3 days covering a range of topics related to peer-befriending, health and safety, and dealing with adverse events. ► Treatment dose set a priori. Six 1-hour visits over 3 months (two further optional visits over 6 months). ► Supervision of befriending. Study design (monthly group while they are befriending and additional individual contact as needed) to monitor deviations from the protocol (eg, in no and length of visits). ► Befrienders completed an aphasia friendly record form after each participant contact indicating length and content of visit and submitted to supervisor. ◄ No (and length) of training and supervision sessions recorded ◄ No of group supervision sessions attended by each befriender ◄ Count of visits ◄ Median length of visits</td>
</tr>
<tr>
<td>Ensure equivalent dose across conditions</td>
<td>► The control condition in SUPERB received usual care only as opposed to the intervention condition who received usual care + peer-befriending. Uptake of services was monitored by documenting the no and frequency of contacts with therapy services, GP appointments and total social and healthcare costs using the Adapted Client Service Receipt Inventory (CSRI) (for both conditions). Information was gathered: at 4 months (following the intervention) and at 10 months. ◄ Group comparisons on contacts and NHS services (reported in health economic paper), stroke and befriending services</td>
</tr>
<tr>
<td>Plan for implementation setbacks</td>
<td>► Training to befrienders was staggered to accommodate a range of geographical areas. ► Monthly group supervision for befrienders to monitor implementation and give additional information and resources as and when needed. ► Individual supervision (face to face or remote) as and when needed. ► All training and supervision of befrienders videotaped to monitor consistency of training and supervision. ◄ No of group supervision sessions attended by each befriender ◄ Amount of individual supervision provided to each befriender ◄ Topics discussed for each group supervision session recorded</td>
</tr>
<tr>
<td>Training providers (ie, befrienders)</td>
<td>► All befrienders working on the project were people with mild-moderate aphasia, at least 1 year poststroke and had to meet further predetermined inclusion and exclusion criteria as described in protocol. ► Befrienders trained by the same two trainers (a qualified speech and language therapist and a clinical linguist) using set training materials which included a study-adapted version of the treatment manual which covered a range of topics (eg, the role of a befriender, hopes and fears, dealing with challenging situations) and a befriender handbook that had key information in an aphasia-accessible format. ► Befrienders trained in groups of up to five. ► All training sessions videotaped. ◄ No (and length) of training sessions recorded ◄ Training adherence rated against fidelity checklists and inter-rater and intrarater reliability calculated. Acceptable adherence: &gt;80% of checklist behaviours rated as present. Reliability: &gt;0.60 is considered good.</td>
</tr>
</tbody>
</table>

### Standardise training

► All befrienders working on the project were people with mild-moderate aphasia, at least 1 year poststroke and had to meet further predetermined inclusion and exclusion criteria as described in protocol. ► Befrienders trained by the same two trainers (a qualified speech and language therapist and a clinical linguist) using set training materials which included a study-adapted version of the treatment manual which covered a range of topics (eg, the role of a befriender, hopes and fears, dealing with challenging situations) and a befriender handbook that had key information in an aphasia-accessible format. ► Befrienders trained in groups of up to five. ► All training sessions videotaped.

### Ensure provider skill acquisition

► Trainers checked understanding and used variety of training techniques to ensure befriender engagement and skills acquisition (eg, group discussion, pair work, raised questions and issues, and invited befrienders to express their own opinions about befriending). ◄ 12 (of 24 items) of training fidelity checklist considered befriender involvement in discussing content or raising questions or issues. ◄ Training adherence rated and inter-rater and intra-rater reliability calculated (see criteria above).

<th>Goal</th>
<th>Strategies used in SUPERB</th>
<th>Metrics and criteria (primary metrics in bold)</th>
</tr>
</thead>
</table>
| Minimise therapist (ie, befriender) drift | ► Monthly group supervision of befrienders while actively befriending (and attendance recorded), providing opportunity to share experiences and discuss difficulties that had arisen from intervention visits. Supervision provided by supervisor who was the qualified speech and language therapist involved in the training.  
  ► Individual supervision (face to face or remote) as and when needed.  
  ► All group supervision sessions (except first and last) videotaped and independently rated for adherence against fidelity checklist with timely feedback given to supervisor.  
  ► A single intervention visit (of 6) was videotaped and independently rated for adherence against fidelity checklist with timely feedback given to the befriender by the supervisor. | ► No (and length) of group supervision sessions.  
  ► No of group supervision sessions attended by each befriender.  
  ► No of befrienders in each group supervision session.  
  ► Amount of individual supervision provided to each befriender.  
  ► Topics discussed for each group supervision session recorded.  
  ► Supervision adherence rated against fidelity checklist and inter-rater and intrarater reliability calculated (see criteria above).  
  ► Intervention visit adherence rated and inter-rater and intrarater reliability calculated (see criteria above). |
| Accommodate provider (ie, befriender) differences | ► Two trainers delivered each training session despite the small no of befrienders trained (≤5) to ensure individual needs were accommodated (eg, by communication support, checking, understanding).  
  ► Befrienders were trained in communication skills for different people with aphasia (mild, moderate, severe).  
  ► Befrienders were trained to deal with different types of participants (eg, quiet, talkative).  
  ► Trainers accommodated differences between befrienders in monthly group and individual supervision sessions. | ► 12 (of 24 items) of training fidelity checklist considered befriender involvement in discussing content or raising questions or issues.  
  ► Training adherence rated and inter-rater and intrarater reliability calculated (see criteria above). |
| Delivery of treatment | ► Matching information about befrienderes was made available to befrienders.  
  ► Befrienders recorded content of visits in aphasia-friendly record forms which were checked by supervisor for deviations from protocol regularly and feedback given.  
  ► Group and individual supervision sessions to discuss befriender differences and deviations minimised through supervisor feedback.  
  ► Participant complaints monitored and matching breakdowns recorded.  
  ► All befrienders interviewed about their experiences of delivering the intervention.  
  ► A purposive sample of participants (n=10) interviewed to explore their perceptions of the intervention and befriender ability to provide the intervention. | ► Matching criteria for each befriender-befriendee recorded.  
  ► No adverse events in relation to matches recorded.  
  ► No of visits rescheduled and reasons recorded.  
  ► Qualitative data (reported elsewhere). |
| Control for provider differences | ► One of (six) intervention visits and all (but first and last) supervision sessions were videotaped and independently rated for adherence against a checklist.  
  ► Adherence ratings fed back to supervisor to give information to befrienderes either individually, or through group supervision sessions.  
  ► Monthly group supervision sessions conducted to monitor delivery of intervention. | ► Intervention visit and supervision adherence rate and reliability calculated (see criteria above).  
  ► Topics discussed for each group supervision session recorded.  
  ► No of supervision sessions attended |
| Reduce differences within treatment | ► No of hours of supervision (individual and group) to befrienderes recorded.  
  ► Supervisor monitored befrienderes to ensure the correct no of sessions were given to participants.  
  ► Adherence to the protocol for all (but first and last) supervision sessions and one (of six) intervention visits videotaped and independently rated for adherence against a fidelity checklist.  
  ► All befrienderes completed aphasia friendly record forms for each intervention visit, which were monitored by supervisor. | ► Intervention visit and supervision adherence rate and reliability calculated (see criteria above).  
  ► No of intervention visits was recorded with any protocol deviations or problems recorded.  
  ► Completion rates for aphasia friendly record form recorded (>80—good)  
  ► Befriendee participation in supervision recorded (details above). |

<th>Goal</th>
<th>Strategies used in SUPERB</th>
<th>Metrics and criteria (primary metrics in bold)</th>
</tr>
</thead>
</table>
| Minimise contamination between conditions | - Participants in control arm were not aware of what intervention was tested. Two-stage consent process where all participants first consented to a study about adjustment poststroke and aphasia and only participants randomised to the intervention arm were given information about befriending intervention and asked to consent to this arm.  
- Recruitment sites selected on the basis that no befriender intervention was available in that setting.  
- Befrienders were trained to only give a single intervention.  
- CSRI information were collected to check control group did not receive a different befriending intervention. | - Group comparisons on contacts and NHS services (reported in full in health economic paper), stroke and befriending services, based on CSRI. |

**Receipt of treatment**

| Ensure participant comprehension | - Befrienders were trained on giving information in an accessible way to participants (see handbook) and this was discussed on an ongoing basis within group supervision sessions.  
- One (of six) intervention visits from each match were videotaped and independently rated for adherence against a fidelity checklist.  
- Purposive sample of participants interviewed postintervention about their experiences. | - Intervention visit adherence checklist includes six items on acknowledging the competence of the person with aphasia (four essential; two optional).  
- Intervention visit adherence rate and reliability calculated (see criteria above)  
- No of times accessible communication was discussed in group supervision.  
- Qualitative data (reported elsewhere). |

| Ensure participant ability to use cognitive skills | - One (of six) intervention visits from each match was videotaped and independently rated for adherence against a fidelity checklist. | - Visit adherence checklist includes nine (out of 16) items on acknowledging and revealing the competence of the person with aphasia.  
- Intervention visit adherence rate and reliability calculated (see criteria above). |

| Ensure participants ability to perform behavioural skills | - Not directly assessed. |

**Enactment of treatment skills**

| Ensure participant use of cognitive skills | - Purposive sample of participants interviewed post-intervention and 6 months later to explore their experiences and impact of intervention. | Qualitative data (reported elsewhere) |
| Ensure participant use of behavioural skills | - Purposive sample of participants interviewed postintervention and 6 months later to explore their experiences and impact of intervention. | Qualitative data (reported elsewhere) |

GP, general practitioner; NHS, National Health Service; RCT, randomised controlled trial; SUPERB, SUpporting wellbeing through Peer-befriending.
regular supervision (monthly group, one-to-one as and when needed) to deliver the intervention as intended. Befrienders were matched with and introduced to their participant with aphasia soon after and within 1 month of randomisation. Matching criteria included geographical location and preferences around sex, cultural factors (eg, ethnicity, religion, languages spoken), age, and personal interests. After they met, both parties had the option to request a rematch, but this did not happen. Befrienders worked with 2–4 participants during the project and no more than two at any one time.

Befrienders visited participants in their own homes six times over a period of 3 months (each visit ~1 hour). Another two optional visits within the next 6 months could also be offered for a gradual transition to the end of peer-befriending. The schedule and nature of visits was agreed between the pair at their first meeting, as well as possible goals for the intervention (eg, participants might highlight concerns that they would like to discuss or activities that they would like to pursue). Subsequent visits included: conversation, problem solving, trips out and joint activities.

After each visit, to control for differences between befriender and subject adherence to protocol, befriender completed an aphasia friendly, 12-question record form (including whether a visit was cancelled and reason why, topics discussed, activities undertaken and date and time of next visit). The supervisor helped if necessary and collated the forms during monthly supervision sessions.

Adherence rating: development of fidelity checklists for training, supervision and delivery of treatment

All training sessions, all but first and last supervision sessions, and one of six visits per pair were recorded to be rated for adherence. The visit chosen was not selected randomly but rather for practical reasons: as befrienders experienced difficulties with recording, a mutually convenient visit was chosen for a research assistant to set up equipment, leave for visit to take place and return to collect equipment. Three checklists were developed for the training, supervision and intervention visits (see online supplemental files 1–3). In line with recent recommendations, the development process involved identifying intervention components, reviewing related measures and obtaining user feedback on the checklists’ content. Training checklist items were based on training manual content. Supervision and intervention visit items were based on the Health Behaviour Change Competency Framework which describes the competencies required to develop and deliver interventions; and the Measure of Participation in Conversation and Measure of Support in Conversation which described behaviours integral to communicating with people with aphasia.

The content of each checklist was reviewed through an iterative process involving four authors (KH, SM, NB and BM) with experience of both the befriending intervention and fidelity. Items were either essential or optional. Essential items (rated ‘present’ or ‘absent’) were behaviours considered critical to the delivery of the intervention. Optional items (‘present’, ‘absent’ or ‘not applicable’) were behaviours which would enhance aspects of the intervention but were not critical in every session (eg, discussion of risk and safeguarding in supervision, presence of humour). The training checklist comprised 24 essential items. The supervision checklist comprised 14 items (13 essential). The intervention visit checklist contained 16 items (13 essential, three optional).

The checklists were piloted by an MSc student who rated two training sessions, four supervision sessions and one visit. The ratings were discussed with the two lead authors (NB, KH) and minor changes were made to make item descriptions clearer.

Fidelity rating process

Raters comprised eight MSc Speech and Language Therapy students and one research assistant with a degree in Speech and Language Therapy. No raters were involved in the intervention. Depending on their skill and experience, raters attended a training session of 2–4 hours which involved familiarising them with the checklists, watching and rating session videos using the fidelity checklists and discussing rating discrepancies.

Each session was rated for adherence by two raters, which allowed testing of inter-rater reliability. For intrarater reliability, sessions were rerated by the same rater after a period of at least 2 weeks. Interim fidelity results were fed back to the supervisor to use during befriender supervision to ensure protocol adherence.

Analysis of adherence

The adherence score for each session was calculated by dividing the number of checklist items present by the number of items expected (excluding items recorded as not applicable). These scores were then converted to a percentage score. A score of 80% and above reflected a high level of treatment adherence. To calculate inter- and intrarater reliability, Gwets AC1 was used. This statistic is less susceptible to skew due to prevalence compared with Cohen’s kappa. A reliability coefficient of 0.81–1.00 is considered very good, 0.61–0.80 good, 0.41–0.60 moderate, 0.21–0.40 fair and below 0.20 poor. Reliability was calculated for essential items only. Statistical analyses were carried out using STATA V.13.

RESULTS

Study design

Treatment dose within condition and implementation setbacks: training and supervision

Three training programmes were completed, attended by five, three and two befrienders, respectively. Each befriender attended one training programme. All training sessions were videotaped and completed as intended in 4–6 hours (not including rest periods) over 2–3 days.
and managing relatives. In later sessions, how to communicate with people with aphasia (and of different severities) and endings were commonly discussed. To minimise implementation setbacks (and befriender drift) supervision sessions consistently covered administration issues (63.6%). The seventy-seven individual supervision sessions also helped minimise drift and accommodate befriender differences. Befrienders attended a median of 6 (IQR=6–8) individual sessions, lasting a median of 60 min (IQR=60–70 min).

### Treatment dose within condition: intervention visits

The number (table 3) and length of intervention visits was recorded. Of the 28 people randomised to the intervention arm, 26 gave consent to participate in the befriending intervention. The remaining two were either not interested or were moving overseas for the duration of the intervention. As per protocol, the median number of visits attended was 6 (IQR=6–6.5) with a median length of 60 min (IQR=60–70 min).

### Treatment dose across conditions

Usual care was received in both arms of the trial and equivalence of dose assessed. There were no significant differences between the usual care and peer-befriending groups based on the Client Service Receipt Inventory for residential and nursing home care; hospital overnight stays; day patient treatment; accident and emergency visits; general practitioner appointments; physiotherapy, occupational therapy, speech and language therapy sessions; community-based healthcare professionals; dentists; social services; individual travel and out of pocket expenses. Importantly, there were no significant differences between the two arms on total social and healthcare costs and overall total costs. There was a higher number of outpatient appointments for the control group at 10 months (p=0.04) to explore contamination between conditions, we looked in more detail at support services such as befriending, stroke groups and other support services (eg, church support, gym groups, charity stroke co-ordinator visits). One participant from the intervention condition at the 4-month assessment point reported receiving four visits by a Red Cross volunteer providing instrumental support with community mobility. No participant reported receiving peer-befriending (outside that delivered in the intervention arm). An equal number of participants from both conditions were going to stroke groups at 4 (n=16) and 10 months (n=10). A small number of

7.5 (IQR=7–8) individual sessions, lasting a median of 10 min (IQR=10–15).
participants received other support services across arms (n=4 in intervention vs n=3 in usual care at 4 months; n=2 in intervention at 10 months).

Training providers
Standardisation of training and provider skill acquisition
Adherence for training sessions ranged from 91.7% to 100%. For the 12 items in the checklists that more closely tapped into befriender skill acquisition and accommodating befriender differences, 10/12 (83%) were rated as present by both raters, at all trainings. Only 1–2/24 items were rated as absent in 4/9 training ratings. Training inter-rater reliability was very good (Gwets AC1 0.91–0.96, p<0.001). Intra-rater reliability was very good for one training session (Gwets AC1=0.95 (0.85–1.0), p<0.001), with no variability between ratings for the remaining sessions (rated 100%).

Minimising befriender drift and accommodating differences
Adherence for supervision sessions ranged from 83% to 100%, based on 22/25 sessions (first and last excluded as planned; fifth session not recorded due to human error). Only two items were rated as absent. Inter-rater reliability could not be calculated (no variability in scores, that is, all essential items rated present by both raters). Intra-rater reliability was calculable and very good for one supervision session (Gwets AC1=0.90 (95% CI 0.66 to 1.00), p<0.001), with perfect agreement for remaining sessions.

Delivery of treatment
Aspects of the fidelity of the treatment delivery that relate to supervision (in terms of controlling for befriender differences, reducing differences in treatment, ensuring adherence to protocol) and group comparisons of services received (to minimise contamination effects) go across categories and have been covered under study design and training of providers above. In this section, the focus is primarily on the intervention visits.

Controlling for befriender differences and adherence to protocol: intervention visits
Participants were matched with befrienders according to set criteria (table 4). Given that befrienders had to travel to the participant’s home, geography was the major deciding factor. To control for differences between befrienders, researchers consistently considered practicabilities (eg, smokers, pets), interests and hobbies, and commonalities in terms of ethnic/cultural background, religion and sex. Most participants did not mind what the ethnic or religious background, age or sex of the befriender was (16/26; 61.5%). Where participants did indicate a preference, it was related to a befriender’s sex (6/26; 23.1%), ethnic background (3/26, 11.5%), age (2/26, 8%) and religious background (1/26, 3.8%).

</table>

No adverse events were recorded for any of the 26 matches. Two participants who initially gave consent to participate in peer-befriending withdrew before the first visit as they did not feel they had the time to participate or felt uncomfortable with having visitors in their home. For the remaining 24 participants, four befrenders were matched with three participants, three with two participants; two with one participant; and one befriender was matched with four participants. Six visits were completed by 21 (87.5%) of befrenders. Of the three participants who did not complete the required number of visits, one could not be contacted after the third visit, one stopped as they felt they did not need more visits, and for the last one, their significant other did not feel the visits were beneficial.

Further evidence of controlling for befriender differences and ensuring adherence to protocol come from visit statistics and the befriender record forms. Of the 143 visits completed, 116 (79.5%) happened as planned, 27 (18.5%) were rescheduled and only three (2.1%) were cancelled. Of those rescheduled, 22 (81.5%) were rescheduled only once. Reasons for first rescheduled or cancelled visits were related to person with aphasia (50%), peer-befriender (40%) or other reasons. Across the 143 visits, befrenders completed the aphasia-friendly record form for 139 visits (97.2%) with a median of 11 (of 12) responses recorded on each form (IQR=10–11). These forms were checked by the supervisor to ensure intervention was delivered as intended.

Reducing differences within treatment
In terms of adherence of intervention visits, of the 24 participants that had befriending visits, 20 videotaped visits were obtained; four participants completed fewer than the required six visits and were unable to be videotaped during the intervention period for practical reasons. Adherence for intervention visits is reported in table 5 and ranged from 66.7% to 100%, with only one visit rated below 80% by one rater. Across the 20 visits, nine different checklist items were rated as absent on at least one occasion. The three items most often reported as absent were: ability to manage the physical and social
environment, give relevant support to the befriendee and have a natural and non-patronising conversation.

For inter-rater reliability, there was a moderate (Gwets AC1=0.44 (95% CI −0.15 to 1.00), p=0.13) to very good level of agreement (Gwets AC1=0.82–1.00, p<0.001) between the two raters for eight intervention visits, with perfect agreement for the remaining sessions (n=12). Intrarater reliability was good to very good for four visits (Gwets AC1=0.76–1.00, p<0.01), with perfect agreement for other sessions (n=16).

Treatment receipt
Some fidelity strategies span across categories. Aspects of fidelity of treatment receipt that related to training (eg, communication skills training) and supervision (eg, number of times communication was discussed) have been covered above.

Ensuring participant comprehension of the intervention
Checklist items that rated acknowledging the competence of the person with aphasia were reviewed. The essential items (n=4) related to how the befriender created a natural, non-patronising and sensitive conversation, that demonstrated active listening of the thoughts and concerns of the participant and responded in a way that was sensitive and respectful. These four items were rated as present for 18/20 visits. The optional items (n=2) related to how a befriender used humour to help participants (eg, to reduce tension) and how they responded to a participant’s humour. These two items were frequently rated as not applicable in 10/20 and 9/20 visits.

Ensuring participant use of cognitive skills
Checklist items that rated the ability of the befriender to acknowledge and reveal the competence of the person with aphasia were reviewed (three additional essential items). All items were rated as present with the exception of one item that was rated as absent in 2/20 visits by a single rater.

Treatment enactment
Treatment enactment of befriending is complex and relates not only to participant activities but also their feelings, identity and coping. Qualitative data from the SUPERB trial are rich and extensive and capture treatment enactment; they are reported elsewhere. Here, we provide some illustrative comments, using pseudonyms, that demonstrate a degree of treatment enactment. There were instances where participants with aphasia undertook activities that they would not have done if it were not for their befriender. One participant, Betsy did not like to go

*Time 1 and 2 refer to rating time points by the second rater to calculate intrarater reliability.
out but said that seeing her befriender, who she felt was like her, going out helped her start going out.

Other participants reflected on taking on the advice of the befrienders. They valued that befrienders gave advice from personal experience. Tips, such as recommending local stroke support groups and a taxi-card service, were perceived as helpful and had been acted on. James said a key realisation for him was that his befriender was still able to drive, and that he could aspire to that too. Ivy continued to meet her befriender at a local stroke group, which he had first invited her to.

**DISCUSSION**

We planned and employed a range of strategies to ensure the fidelity of the peer-befriending intervention for people with aphasia in the SUPERB trial. Fidelity across a range of categories was high. All befrienders attended the training and a high number of group supervision sessions. Over 80% of participants received the required six 1-hour intervention visits. Adherence was high for training and supervision sessions and moderate-to-high for intervention visits. Fidelity ratings were reliable: very good for the training and supervision sessions; and moderate to very good for the intervention visits.

High adherence to fidelity checklists is consistent with the few other studies in aphasia. High adherence to training and supervision is likely due to using the same set of materials, structured agenda and the same experienced facilitators across all sessions. Strategies to support the befrienders included monthly group sessions and individual supervision as required, which were key to preventing drift in their skills and ensured they completed visits. Monthly group meetings have previously been offered for other befriending studies. Befrienders were highly supported to attend group supervision particularly during the time they were completing intervention visits. Supervision provided an opportunity to minimise implementation setbacks (eg, managing communication, boundaries) and to refamiliarise befrienders with relevant topics from the training (eg, risk and safeguarding, ending visits).

There was excellent adherence for a large proportion of intervention visits. To maximise protocol adherence, monitoring fidelity prospectively ensured that differences within the intervention arm (and between befrienders) were minimised. Deviations could be fed forward to the facilitator of the supervision sessions to review and discuss visit related topics. Befrienders were able to promote supported conversation for participants where they listened to the opinions and concerns of people with aphasia and gave them the opportunity to speak. Even those befrienders (n=4) who were matched with participants with severe aphasia could accommodate their skills to communicate effectively with participants. Nevertheless, some variability was noted in adherence for the intervention visits. The nature of the sessions may help to explain this. More highly structured sessions (eg, training and supervision) tend to show greater fidelity. Befriending visits are less structured and inherently require a more subjective judgement, for example, whether a befriender has spoken in a natural and non-patronising manner or used and responded appropriately to humour. Greater rater training to clearly explain vague or ambiguous terms and establish a predetermined level of agreement before rating study samples may help. However, more variability may also reflect lack of/developing skills for some befrienders, during their initial pairings before fidelity checks had occurred. Subsequent feedback ensured befrienders displayed the necessary skills for future matches.

Behaviours related to managing the environment, giving support to the participant and having a natural conversation were the ones most commonly rated as absent. However, they were mostly rated as absent by a single rather than both raters. This finding may suggest they were missed, too subtle to have been observed or difficult to assess, with training inadequate for helping raters accurately recognise them. Therefore, clearer specification of behaviours may be needed. In half the evaluated sessions both raters judged the use and response to humour as ‘non-applicable’, suggesting these items should remain optional. Humour is considered integral to interactions with friends but there may be fewer opportunities for humour with less familiar people, and not all interactions require humour.

This study advances our understanding of fidelity beyond simply adherence to an intervention protocol, as in previous studies. While a focus on implementation and factors that may moderate fidelity could be appropriate for pragmatic trials, the results of this study demonstrate the importance of planning a comprehensive set of fidelity practices at the outset of an early explanatory trial, like SUPERB. Through consideration of strategies proposed by Bellg et al, our understanding of fidelity moves beyond treatment delivery alone. Insight is gleaned of the planned strategies that led to the fidelity results, such as, same skilled facilitators, standardised training with set materials, regular and flexible supervision, feeding fidelity findings into supervision. This latter strategy did not happen with one befriender early in the trial who had low adherence; in contrast, overall, discussing fidelity of visits in supervision before giving a befriender a second match ensured differences were considered, engagement encouraged and understanding of important components of intervention maximised.

Another strength of this study was the broad range of information gathered about the dosage of training, supervision and intervention; adherence and reliability. In SUPERB, 100% of training, 88% of supervision and 14% of intervention sessions were checked by two independent raters for adherence and all of these were rated for reliability. In most studies, a proportion of sessions (usually 10%–33%) is rated for adherence with a proportion of those second rated for reliability. Furthermore, reliability was calculated in multiple ways which is...
CONCLUSION

Peer-befriending for people with aphasia post-stroke was delivered with good-high fidelity in the SUPERB RCT. The study was novel as one of still only a handful of aphasia trials reporting fidelity in a systematic way, based on a theoretical framework. The study demonstrated the importance of comprehensive planning for fidelity at the outset of a trial and the need for ongoing rigorous monitoring throughout the trial to ensure an intervention is implemented as intended.
