Abstract

Objectives: To quantify conflict events and access across countries that remain to be certified free of transmission of *Dracunculus medinensis* (Guinea worm disease) or require post-certification surveillance as part of the Guinea Worm Eradication Program (GWEP).

Setting and participants: Populations living in Guinea worm affected areas across seven pre-certification countries and 13 post-certification Sub-Saharan African countries.

Outcome measures: The number of conflict events and rates per 100,000 population, the main types of conflict and actors reported to be responsible for events were summarised and mapped across all countries. Chad and Mali were presented as case studies. Guinea worm information was based on GWEP reports. Conflict data were obtained from the Armed Conflict Location and Event Data Project. Maps were created using ArcGIS 10.7 and access was measured as regional distance and time to cities.

Results: More than 98,000 conflict events were reported between 2000-2010, with a significant increase since 2018. The highest number and rates were reported in pre-certification Mali (n=2556; 13.0 per 100,000), South Sudan (n=2143; 19.4), DRC (n=7016; 8.1), and post-certification Nigeria (n=6903; 3.4), Central Africa Republic (n=1251; 26.4), Burkina Faso (n=2004; 9.7). Violence against civilians, protests and battles were most frequently reported with several different actors involved including Unidentified Armed Groups and Boko Haram. Chad and Mali had contracting epidemiological and conflict situations with affected regions up to 700km from the capital or 10 hours to the nearest city.

Conclusions: Understanding the spatial-temporal patterns of conflict events, identifying hotspots, the actors responsible, and their sphere of influence is critical for the GWEP and other public health programmes to develop practical risk assessments, deliver essential health interventions, implement innovative surveillance, determine certification, and meet the goals of eradication.

Strengths and limitations of this study

- Conflict and insecurity is a major problem in many of the African countries that remain to be certified free of transmission of *Dracunculus medinensis* (Guinea worm disease) or require post-certification surveillance; we characterise the rate of increase in violent events and the main actors in these countries over the last two decades using various publicly available databases
- We present case studies for Mali and Chad to highlight the multifaceted epidemiological and conflict situations, the challenging access and safety issues, which will require bespoke risk assessments and innovative strategies to reach certification
- The extensive georeferenced conflict data used in the study is a valuable resource to use as a first step in assessing a situation, however, given the limitations of secondary data, it will be important to supplement this information with details from local, reliable sources and trusted partners on the ground
- We recommend that the methodology and databases are used by countries and the World Health Organization in preparation for certification missions for the Guinea Worm Eradication Programme, and used more widely as a management and risk assessment tool for other research and health programmes working in areas and countries of complex emergencies and insecurity

Introduction

Guinea Worm or Dracunculiasis is one of two infections that have been designated formally by the World Health Assembly as diseases targeted for eradication, the other being poliomyelitis.[1–3] Yaws eradication has also been included as a target in the recently approved World Health Organization(WHO) Neglected Tropical Disease (NTD) Road Map 2021-2030.[4] Eradication requires Certification of each member state of the United Nations as being free of transmission of the infectious agent *Dracunculus medinensis*. The Guinea Worm Eradication Program (GWEP) has more recently adopted specific definitions approved by the International Commission for the Certification of Dracunculiasis Eradication (ICCDE), which reflect the criteria required to confirm the elimination from a country and following that the need for all countries to be free of transmission prior to Global Certification of Eradication by the World Health Assembly.[2]

Elimination of dracunculiasis is the confirmed absence of the emergence of adult female worms (the interruption of transmission of D. medinensis) in humans and animals for three consecutive years or longer from a country with such a low risk of reintroduction of the parasite that preventive measures could be reduced to a strict minimum. Worldwide eradication of dracunculiasis is the confirmed absence of the emergence of adult female worms (defined as compatible with the interruption of transmission of D. medinensis) in humans and animals for three years or longer at the global level.[2]

Recently, the challenges of certifying elimination in countries and then eradication globally have been highlighted.[5,6] Whilst the numbers of human cases have declined by over 99% since the programme began in the late 1980s[7] from an estimated 3 million cases per year to some 27 cases reported to date in 2020,[3,8,9] the problems of animal infections, in particular in dogs, has arisen and in Chad new modes of transmission have been uncovered involving paratenic hosts in fish, predominantly small “fingerlings”. [10–13] Whilst Chad is the most serious challenge to global eradication given the high numbers of dogs reported infected annually (over 1900 in 2019 and 1500 in 2020),[14,15] dogs have been found infected consistently, albeit in small numbers in Mali, Ethiopia and Angola.[2,3]

Whilst the challenge of animal infections is a recent phenomenon, all countries previously certified have failed to report any animal infections despite surveillance in formerly endemic areas.[15] However, a significant further challenge is the problem of access to insecure areas due to conflict and violence.[5,6,15,16] Five endemic countries require to be certified together with the Democratic Republic of Congo (DRC) and Sudan (pre-certification countries), whilst not currently endemic,

1
2
3 having not reported a human case since 1958 and 2002 respectively, require to be verified as free of
4 transmission based on a visit from an International Certification Team (ICT). If access due to
5 insecurity and conflict is curtailed or limited given the onus on any ICT is to “prove a negative” as far
6 as is possible would be impaired and would limit the validity of any report which recommended that
7 the country was free of transmission.
8
9
10

11
12 At present there is no standardised approach to evaluate the level of conflict risk in Guinea worm
13 endemic countries which cover vast area of Africa. This is critical as conflict significantly disrupts the
14 implementation of health service delivery, impact assessments, research and surveillance.[17–20]
15 We present in this paper an approach to quantifying the risks in countries yet to be certified, as well
16 as those already certified and require continuing surveillance until global eradication has been
17 declared. Since elimination of transmission was confirmed by the ICCDE in some 13 countries in
18 Africa, the security situation has changed as civil unrest will have impacted on the ability of countries
19 to maintain a level of surveillance compatible with adequate post-certification scrutiny. This applies,
20 in particular to Sahelian countries, where jihadist movements control large swathes of some
21 countries and where national authorities have limited access or control -Niger, Burkina Faso, Nigeria,
22 Senegal, Mauritania and Cameroon whereas inter religious conflict in Central African Republic (CAR)
23 prevents access to the area bordering Chad.[21,22] In the DRC there is significant conflict in eastern
24 regions of the country and the border of South Sudan and Sudan has a high level of insecurity.

31
32
33
34

35 To address this challenge, we examined the number of conflict events from 2000 to 2020 to highlight
36 long-term temporal trends in countries previously certified as free of transmission, pre-certification
37 countries those currently endemic and those countries that require certification but which have not
38 recorded a case of the infection since the inception of the GWEP in the late 1980's. We quantified
39 the number of conflict events and rates per 100,000 population for the most recent years, highlight
40 the main types of conflict and the main actors responsible, as well as present specific data from
41 Chad and Mali as case studies. This approach can also be applied to the polio eradication programme
42 and has implications for other health interventions.

Methods

Study area

The cross-sectional study included sub-Saharan African countries that were categorised as those in the pre-certification stage and those in the post-certification stage.

Pre-certification countries included those currently endemic for dracunculiasis, namely Angola, Chad, Ethiopia, Mali and South Sudan (from 2011 Independence onwards), and countries with historical evidence of Guinea worm but are yet to be certified as free from dracunculiasis, including the DRC and Sudan.

Post-certification countries included Benin, Burkina Faso, Cameroon, CAR, Cote d'Ivoire, Ghana, Kenya, Mauritania, Niger, Nigeria, Senegal, Togo and Uganda. The dates when these countries were certified free of transmission are provided in Molyneux et al..[5] See Figure 1 for the map of pre-certification and post-certification countries which cover vast geographical regions of sub-Saharan Africa covering more than 15 million square kilometres (km²)[23] with poor accessibility to urban centres or cities.[24] The land area of each country is shown in Table 1 with Angola, Chad, DRC, Mali, Niger and Sudan more than 1.2 million km² in size.

Figure 1. Map of pre-certification and post-certification countries in sub-Saharan Africa

Data sources

To examine Guinea worm status in relation to spatial and temporal distribution of conflict events and regional access within each country, several data sources were obtained;

- Guinea worm information was based on World Health Organisation (WHO) annual reports and Dracunculiasis Eradication Portal,[2,15,25] and GWEP reports by The Carter Centre and the Centres for Disease Control and Prevention.[3,8]
- Conflict data were downloaded from the Armed Conflict Location and Event Data Project (ACLED),[26,27] including geo-referenced location data on conflict event types categorised as battles, riots, protests, strategic developments, explosions/remote violence and violence against civilians and actors i.e. groups of people or organisations reported to be responsible for the events (definitions available on ACLED website)[27] for the period from January 2000 to October 2020.
- Population were obtained from the World Bank databank and based on 2019 estimates.[23]

- Administrative boundaries were obtained from the United Nations Office for the Coordination of Humanitarian Affairs (OCHA).[28]
- Accessibility information was based on regional distance (kilometres (kms)) to the capital city and from modelled maps of 'Accessibility to cities', quantified as travel time in minutes (converted to hours) to the nearest high-density urban centre or city at a resolution of 1 x 1 km for 2015.[24]

These data sources represent the best available in the public domain, and it is acknowledged that there may be some missing cases and conflict event data, and differences in population estimates, country size and accessibility compared with other sources.

Conflict and population data were downloaded and collated in Microsoft Excel (Microsoft Corporation, Redmond, WA) and the administrative boundary and accessibility to cities data were downloaded and imported into geographical information software ArcGIS 10.7 (ESRI, Redlands, Ca) for mapping and analysis.

Patient and public involvement

No patient was included in this study.

Data analysis and mapping

First, the number of conflict events for the pre-certification and post-certification countries were summarised for years from 2000 to 2020 to highlight long-term temporal trends and high-conflict Guinea worm countries.

Second, the overall number of conflict events and rates per 100,000 population for the most recent years, 2018 to 2020, were quantified for each country. The different types of conflict events were tabulated and mapped, and the countries with the most events and highest rates per population were identified as high-conflict countries. The main actors reported to be responsible for the highest number of events in the high-conflict countries were summarised.

Finally, the situation in Chad and Mali since 2018 was presented as contrasting case studies, and included a summary and maps of the number of Guinea worm human and/or animal cases and regions affected; the number of conflict events types and main actors in each region; and accessibility of each region measured as the distance (kms) between the centre of each region and each capital city, and the average time (hours) of each region to high-density urban centre or city.

Results

Overall summary 2010-2020

The total number conflict events reported for pre-certification and post-certification countries between 2000-2020 is shown in Figure 2A and 2B (data available in Supplementary file 1). Overall, the temporal trends in conflict events across all countries were similar with a marked increase from 2010 onwards.

In the five endemic countries, a total of 18,895 conflict events were reported between 2000-2020 with the highest numbers in South Sudan (n=6986 from 2011 onwards) representing 37.0% of the total. In the first decade between 2000-2010, a total of 2437 events were reported, which increased 6.8-fold to 16,458 events between 2011-2020, with 41.5% reported in the last three years since 2018. In the two countries yet to be certified, a total of 30,805 events were reported with the highest numbers in DRC (n=17,385; 56.4%). Between 2000-2010, a total of 6387 events were reported, which increased 3.8-fold to 24,418 events between 2011-2020, with 41.5% reported in the last three years.

In the post-certification countries, a total of 48,615 events were reported with the highest numbers in Nigeria (n= 17,763) representing 36.5% of the total. In the first decade between 2000-2010, the 10,244 events were reported, which increased 3.7-fold to 38,371 events between 2011-2020, with around one third (37.3%) reported in the last three years.

Figure 2. Number of conflict events reported in pre-certification and post-certification countries between 2000 – 2020

Summary of conflict events in recent years 2018 – 2020

Pre-certification countries

In the five endemic countries, an overall total of 6,832 conflict events were reported between 2018-2020 (Table 1A; Figure 3). The highest numbers and rates per 100,000 population were reported in Mali (n=2556; 13.0 per 100,000) and South Sudan (n=2143; 19.4 per 100,000). Overall, the most frequently reported events included violence against civilians (n=2373), protests (n=993), and battles (n=2055) with South Sudan reporting the highest number violence incidents against civilians (39.1% of total) and battles (46.4%) and Ethiopia reporting the highest number of protests (49.8%). South

1
2
3 Sudan also reported the highest rates of violence against civilians (8.4 per 100,000), and battles (8.6
4 per 100,000), and Mali the highest rates of protests (1.3 per 100,000). A summary of the actors
5 reported to be responsible for the highest number and type of conflict events in the high-risk
6 countries is shown in Table 2A. For Mali, the actors reported for the most events included JNIM:
7 Group for Support of Islam and Muslims (n=661); Unidentified Armed Group (Mali) (n=434) and
8 Protesters (n=261). For South Sudan, the actors included the Military Forces of South Sudan (2011-)
9 (n=543), Unidentified Armed Group (South Sudan) (n=399) and the Sudan People's Liberation
10 Movement-In Opposition (n=157).
11
12
13
14
15
16
17

18 In DRC and Sudan, a total of 10,139 events were reported between 2018-2020 (Table 1B; Figure 3).
19 The highest number and rate per 100,000 population were reported in DRC (n=7016; 8.1 per
20 100,000). The most frequently reported events included violence against civilians (n=3242) protests
21 (n=2656), and battles (n=2628) with DRC reporting the highest number of these events representing
22 76.6%, 38.6% and 86.2% of the total respectively. The DRC also reported the highest rates of
23 violence against civilians (2.9 per 100,000) and battles (2.6 per 100,000), and Sudan the highest rates
24 of protests (3.8 per 100,000). A summary of the actors reported to be responsible is shown in Table
25 2A. The actors associated with the two most reported events in both countries included an
26 Unidentified Armed Group (DRC=1236; Sudan =233), and Protesters (DRC=975; Sudan=1590).

Post-certification countries

In the post-certification countries, a total of 18,146 events (3.9 per 100,000) were reported between 2018-2020 (Table 1B; Figure 3). The highest numbers reported were in Nigeria (n=6903), Cameroon (n=2517), Burkina Faso (n=2004), and the highest rates in CAR (26.4 per 100,000), Burkina Faso (9.9 per 100,000) and Cameroon (9.7 per 100,000). The most frequently reported events included violence against civilians (n=5803) protests (n=4023), and battles (n=3891) with Nigeria reporting the highest number of these events representing 38.3%, 43.4% and 42.5% of the total respectively. The CAR reported the highest rates of battles (7.4 per 100,000), and violence against civilians (9.7 per 100,000), and Mauritania the highest number of protests (8.5 per 100,000).

A summary of the actors reported to be responsible for the highest number and type of conflict events in the high-risk countries is shown in Table 2B. For Nigeria, the actors associated with the two most reported events included Protesters (Nigeria) (n=1735) and an Unidentified Armed Group (n=1033). For Cameroon, the actors included the Islamic State (West Africa) and/or Boko Haram - Jamatu Ahli is-Sunnah lid-Dawatai wal-Jihad (n= 817) and Military Forces of Cameroon (1982-) (n=642). For CAR, the actors included an Unidentified Armed Group (CAR) (n=271) and the UPC: Union for Peace in the Central African Republic (n=155). For Burkina Faso, the actors included JNIM: Group for Support of Islam and Muslims and/or Islamic State (Greater Sahara) (n=455) and JNIM: Group for Support of Islam and Muslims (n= 340).

Chad case study

The capital N'Djamena and six regions reporting Guinea worm human cases and/or animal infections between 2018 and 2020 are shown in Figure 4A and 4 B, together with the conflict event types reported in Chad, and the neighbouring pre-certification country of Sudan and post-certification countries of Cameroon, CAR and Niger.

Guinea worm situation. Human disease cases were reported in 2018 (n=17), 2019 (n=48) and 2020 (n=13). The areas affected included the Chari Baguirmi region, in Bailli (2018; 2019), Bousso (2018; 2019; 2020), Dourbali (2019), Kouno (2019) and Mandelia (2018; 2020) districts; the Moyen Chai region, in Danamadji (2019), Korbal (2018; 2019) Kyabe and Sahr (2018; 2019; 2020) districts; the Salamat region, in Aboudeia (2018; 2019; 2020), Amtiman (2018; 2019) and Haraze (2019); the Tanjile region in Bere district (2018) and the Wadi-Fira region in Matadjana district (2020).

1
2
3 Animal infections, predominately domesticated dog infections were high and reported in 2018
4 (n=1040), 2019 (n=1935) and 2020 (n=1464). The areas affected included the capital N'Djamena
5 (2018) and the Chari Baguirmi (2018; 2019), Mandoul (2018), Moyen Chai (2018; 2019), Mayo-Kebbi
6 Est (2018; 2019) and Salamat (2018; 2019) regions (Figure 4B).
7
8
9

10
11 Conflict events. The highest number of conflict events was reported in N'Djamena (n=104) (Table
12 3A), were predominately protests (44 events) with protestors reported as the main actors. In the
13 other Guinea worm affected regions, the number of conflict events was lower and ranged from 0 -
14 13 events in 2018-2020. The main conflict event type in the Chari-Baguirmi region was of violence
15 against civilians (3 events) with Military Forces, Police Forces and Moile Communal Militia the main
16 actors; in Moyen-Chari was battles (2 events; Unidentified Communal Militia Chad); in Salamat was
17 battles (2 events; Nomad and National Guard and Unidentified Communal Militia); in Tanjili was
18 battles (10 events; Fulani Militia, Koutoune Communal Militia; Tandjile Communal militia and
19 Unidentified Armed Group); and in Mayo-Kebbi Est was violence against civilians (4 events; Nomad
20 and National Guard, Military Forces, Unidentified Armed Group (Cameroon and Chad)).
21
22
23
24
25
26
27
28

29 Regional access. The level of access in terms of distance (kms) to the capital N'Djamena and
30 accessibility to a city in hours within Chad and in relation to Guinea worm status and conflict events
31 is shown in Table 3A. Of the Guinea worm affected regions, Salamat (600-700kms) was the furthest
32 from the capital and had the longest estimated time of 10 hours to the nearest city. Of the northerly
33 non-endemic regions, the Lac (n=88), Quadd (n=57) and Tibesti (n=55) had the highest number of
34 conflict events, with Tibesti (900-1000km) the furthest distance and had the longest estimated time
35 of 42.1 hours to the nearest city.

45 *Mali case study*

46
47 The capital Bamako and two regions reporting Guinea worm animal infections in 2018-2020 are
48 shown in Figure 4C and 4D, together with the conflict event types reported in Mali, and the
49 neighbouring pre-certification countries of Burkina Faso, Niger and Mauritania.
50
51
52
53

54 Guinea worm situation. One human case was reported in early 2020 – the first human case reported
55 since 2015. Animal infection, predominately domesticated dog infections were reported in 2018
56 (n=18), 2019 (n=8) and 2020 (n=9). The areas affected included the Mopti region, in Djenne (2018;
57
58
59
60

1
2
3 2019; 2020) district, and the Segou region in Markal (2018), Tominian, Macina (2018; 2019; 2020)
4 and Baroueli (2020) districts (Figure 4D).
5
6

7
8 Conflict events. The highest number of conflict events was reported in Mopti region (n=1206) (Table
9 3B), predominately violence against civilians (561 events) and battles (347 events) with Fulani Ethnic
10 Militia, Groups for Support of Islam and Muslims, Unidentified Armed Group and/ or Military Forces
11 reported as the main actors associated with these events. The main conflict events in the Segou
12 region were battles (55 events) and violence against civilians (44 events) with Group for Support of
13 Islam and Muslims reported as the main actors associated with battles and Military Forces of Mali
14 and Dozo Communal Militia main actors for violence against civilians.
15
16
17
18
19

20
21 Regional access. The level of access in terms of distance to the capital Bamako and accessibility to a
22 city in hours within Mali and in relation to case status and conflict events is shown in Table 3B. Of
23 the Guinea worm affected regions, Mopti was the furthest from the capital Bamako, approximately
24 500-600 km, and had the longest accessibility time of 4.1 hours to the nearest city. Of the
25 unaffected regions, Gao (n=503), and Tombouctou (n=264) had the highest number of conflict
26 events, with Gao (1000-1100kms) the furthest away from the capital, and Tombouctou the longest
27 estimated time of 62.9 hours to the nearest city.

Sikasso	No reports	58	200-300	1.9
Tombouctou	No reports	264	900-1000	62.9

Discussion

The GWEP has made remarkable progress since activities began in the late 1980's with the WHO reporting only tens of human cases in recent years. [15,25] This success has been driven by country commitment, the support from the WHO[2] and The Carter Center[3] and articulating the fundamental public health interventions to eliminate the transmission - case containment, control of copepods, access to safe drinking water (including filtration), regular reporting and surveillance, and instituting a reward system and the follow up of rumours.[5,7]

This paper, however, documents that over the past two decades, the numbers of incidents of conflict and violence have increased dramatically, especially in the last 3 years since 2018. This is not only of concern for endemic countries, but for the two countries yet to be certified, and the 13 countries that were previously endemic for the infection requiring ongoing surveillance.[2] The Guinea worm community have increasingly recognised that certification will face the challenges of acquiring comprehensive and reliable information in conflict zones and in accessing areas where national governments have limited control.[5,8,15] In addition, the porosity of international borders, extensive migration generated by insecurity, inter-country range of many of the actors responsible for violence, and the need for these geographically vast countries to ensure that any Guinea worm case is recognised and reported, highlights the immense challenges programmes face to satisfy the criteria for certifying the absence of transmission and the effectiveness of surveillance.[6]

The characteristics of the situation in areas of West and Central Africa are that there are many groups who are responsible for violence at both national and local levels and their motivations are different, even within the same region.[26,27] Understanding how these challenges for the GWEP can be overcome is essential if the country elimination objective and global eradication certification is to be achieved. Providing detailed data, as described in this paper, is necessary so risk assessments can be made to safely operationalise field work, especially in remote locations where access is limited.[18,29] This underscores the value of understanding the spatial and temporal patterns of conflict, identifying hotspots, the actors responsible and their sphere of influence. This information will allow the potential impact of violence on GWEP activities to be assessed consonant with the need to satisfy the robust criteria established by WHO a country to be certified by the ICCDE based on the information in the detailed national report submitted to WHO, and on which the ICT to base their assessments on the likelihood of the country being free of *D. medinensis* transmission.

We have summarised in detail the magnitude, geographical extent and increasing incidence of conflict and violence in those countries where Guinea worm remains a problem for those responsible for ensuring a successful endgame for eradication, which now has a target of 2030 for

1
2
3 global certification.[4] The scale of the challenge can probably best be illustrated by the fact that
4 the total area of pre-certification countries is similar to continental USA.[23] This WHO NTD
5 Roadmap target implies that all countries that remain to be certified must have zero cases in
6 humans and animals by 2026/7 as a minimum of three years is required of zero global cases must be
7 reported over the period 2027- 2030. This will require intense integrated human and animal
8 surveillance, in countries at present suffering conflict events, with a trend that is regrettably
9 accelerating rather than diminishing. The Chad and Mali case studies highlight the multifaceted
10 epidemiological and conflict situations, the challenging access and safety issues, which will require
11 bespoke risk assessments and innovative strategies to reach certification. A One Health approach
12 including human, animal and environmental components should be considered given the evolving
13 modes transmission,[30,31] taking the cost-effectiveness[32] and conflict context into account.

14
15
16
17
18
19
20
21
22 The case and conflict event data used in this study are valuable resources to use as a first step in
23 assessing a situation. However, as there are some limitations with using secondary data, it will be
24 important to supplement this information with details from local, reliable sources and trusted
25 partners on the ground. The methodology and tools we have used in this paper provide a better
26 understanding of the challenges the GWEP faces and is based on the recent studies undertaken to
27 understand and address the risks for NTD programmes,[33] and should be more widely promoted
28 not only for Guinea worm, but as a management and risk assessment tool for other research and
29 health programmes working in areas and countries of complex emergencies and insecurity.

Contributors

LAKH and DHM conceptualised the paper. LAKH accessed data sources, applied analytical methods and produce maps. Both contributed to the data interpretation, writing the first and final version of the manuscript.

Funding

No specific grant was obtained for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests

LAKH declares no competing interests. DHM is a member of the International Commission for the Certification of Dracunculiasis Eradication

Patient and public involvement Patients and/or the public were not involved in the design, or conduct, or reporting, or dissemination plans of this research.

Data availability statement

All data are available in the paper, supplementary file and accessible from the public data sources.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	6-7
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6-7
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6-7
Bias	9	Describe any efforts to address potential sources of bias	6-7
Study size	10	Explain how the study size was arrived at	6-7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	7
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	N/A
		(b) Describe any methods used to examine subgroups and interactions	6-7
		(c) Explain how missing data were addressed	N/A
		(d) If applicable, describe analytical methods taking account of sampling strategy	N/A
		(e) Describe any sensitivity analyses	N/A
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	8-10
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	N/A
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	8-12
		(b) Indicate number of participants with missing data for each variable of interest	N/A
Outcome data	15*	Report numbers of outcome events or summary measures	8-12
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	N/A

		(b) Report category boundaries when continuous variables were categorized	8-12
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	11-12
Discussion			
Key results	18	Summarise key results with reference to study objectives	13
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	13-
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	13-14
Generalisability	21	Discuss the generalisability (external validity) of the study results	13-14
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	N/A

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Abstract

Objectives: To quantify conflict events and access across countries that remain to be certified free of transmission of *Dracunculus medinensis* (Guinea worm disease) or require post-certification surveillance as part of the Guinea Worm Eradication Program (GWEP).

Setting and participants: Populations living in Guinea worm affected areas across seven pre-certification countries and 13 post-certification Sub-Saharan African countries.

Outcome measures: The number of conflict events and rates per 100,000 population, the main types of conflict and actors reported to be responsible for events were summarised and mapped across all countries. Chad and Mali were presented as case studies. Guinea worm information was based on GWEP reports. Conflict data were obtained from the Armed Conflict Location and Event Data Project. Maps were created using ArcGIS 10.7 and access was measured as regional distance and time to cities.

Results: More than 98,0000 conflict events were reported between 2000-2020, with a significant increase since 2018. The highest number and rates were reported in pre-certification Mali (n=2556; 13.0 per 100,000), South Sudan (n=2143; 19.4), Democratic Republic of Congo (n=7016; 8.1), and post-certification Nigeria (n=6903; 3.4), Central Africa Republic (n=1251; 26.4), Burkina Faso (n=2004; 9.7). Violence against civilians, protests and battles were most frequently reported with several different actors involved including Unidentified Armed Groups and Boko Haram. Chad and Mali had contracting epidemiological and conflict situations with affected regions up to 700km from the capital or 10 hours to the nearest city.

Conclusions: Understanding the spatial-temporal patterns of conflict events, identifying hotspots, the actors responsible, and their sphere of influence is critical for the GWEP and other public health programmes to develop practical risk assessments, deliver essential health interventions, implement innovative surveillance, determine certification, and meet the goals of eradication.

Strengths and limitations of this study

- This study is the first to analyse the impact, extent and challenges facing the Guinea Worm Eradication programme as a result of increased conflict in sub-Saharan Africa.
- The methodology employed is based on conflict data downloaded from the Armed Conflict Location and Event Data Project (ACLED) using geo-referenced location data on conflict event types.
- This real-time data can be used by both endemic countries and international organizations for planning programmatic activities for risk assessment purposes for surveillance and certification planning.
- Such data will inform the time scale for Guinea Worm Certification missions given that access to and information from areas where risk of conflict exists will require innovative approaches to acquire robust epidemiological data as a prerequisite for certification of absence of transmission in a country.

Introduction

Guinea Worm or Dracunculiasis is one of two infections that have been designated formally by the World Health Assembly as diseases targeted for eradication, the other being poliomyelitis.[1–3] Yaws eradication has also been included as a target in the recently approved World Health Organization(WHO) Neglected Tropical Disease (NTD) Road Map 2021-2030.[4] Eradication requires Certification of each member state of the United Nations as being free of transmission of the infectious agent *Dracunculus medinensis*. The Guinea Worm Eradication Program (GWEP) has more recently adopted specific definitions approved by the International Commission for the Certification of Dracunculiasis Eradication (ICCDE), which reflect the criteria required to confirm the elimination from a country and following that the need for all countries to be free of transmission prior to Global Certification of Eradication by the World Health Assembly.[2]

Elimination of dracunculiasis is the confirmed absence of the emergence of adult female worms (the interruption of transmission of D. medinensis) in humans and animals for three consecutive years or longer from a country with such a low risk of reintroduction of the parasite that preventive measures could be reduced to a strict minimum. Worldwide eradication of dracunculiasis is the confirmed absence of the emergence of adult female worms (defined as compatible with the interruption of transmission of D. medinensis) in humans and animals for three years or longer at the global level.[2]

Recently, the challenges of certifying elimination in countries and then eradication globally have been highlighted.[5,6] Whilst the numbers of human cases have declined by over 99% since the programme began in the late 1980s[7] from an estimated 3 million cases per year to some 27 cases reported to date in 2020,[3,8,9] the problems of animal infections, in particular in dogs, has arisen and in Chad new modes of transmission have been uncovered involving paratenic hosts in fish, predominantly small “fingerlings”. [10–13] Whilst Chad is the most serious challenge to global eradication given the high numbers of dogs reported infected annually (over 1900 in 2019 and 1500 in 2020),[14,15] dogs have been found infected consistently, albeit in small numbers in Mali, Ethiopia and Angola.[2,3] The problems of insecurity have been a continuing part of the GWEP for as long ago as 1995 when President Jimmy Carter personally negotiated a “Guinea Worm ceasefire” in South Sudan to enable all programme activities to recommence,[16] whilst Mali has experienced heightened insecurity over recent years making access to some endemic areas difficult.[17] In early 2021 the death of the President of Chad has destabilised the regime and some GWEP Chad programme staff have been evacuated from the country).[3]

1
2
3 Whilst the challenge of animal infections is a recent phenomenon, all countries previously certified
4 have not reported any animal infections despite surveillance in formerly endemic areas.[15]
5
6 However, a significant further challenge is the problem of access to insecure areas due to conflict
7 and violence.[5,6,15,18] Five endemic countries require to be certified together with the Democratic
8 Republic of Congo (DRC) and Sudan , whilst not currently endemic, having not reported a human
9 case since 1958 and 2002 respectively, require to be verified as free of transmission based on a visit
10 from an International Certification Team (ICT). If access due to insecurity and conflict is curtailed or
11 limited given the onus on any ICT is to “prove a negative” as far as is possible would be impaired and
12 would limit the validity of any report which recommended that the country was free of transmission.
13 “Proving a negative” is not possible in any public health or scientific endeavour hence the ICT
14 missions have to balance judgements made on the basis of available information and data supplied
15 by the country.
16
17
18
19
20
21
22
23

24 At present there is no standardised approach to evaluate the level of conflict risk in Guinea worm
25 endemic countries which cover vast areas of Africa. This is critical, as conflict significantly disrupts
26 the implementation of health service delivery, impact assessments, research and surveillance.[19–
27 22] In this paper we present an approach to quantifying the risks in countries yet to be certified, as
28 well as those already certified but require continuing surveillance until global eradication has been
29 declared. Since elimination of transmission was confirmed by the ICCDE in some 13 countries in
30 Africa, the security situation has changed. Civil unrest and insecurity will have impacted on the
31 ability of countries to maintain a level of surveillance compatible with adequate post-certification
32 scrutiny. This applies, in particular to Sahelian countries, where jihadist movements control large
33 swathes of some countries and where national authorities have limited access or control. This is
34 exemplified in Niger, Burkina Faso, Nigeria, Senegal, Mauritania and Cameroon whereas in Central
35 African Republic (CAR) inter religious conflict prevents access to the area bordering Chad.[23,24] In
36 the DRC there is significant conflict in eastern regions of the country and the border of South Sudan
37 and Sudan has a high level of insecurity.

47
48

49 To address this challenge, we examined the number of conflict events from 2000 to 2020 to highlight
50 long-term temporal trends in countries i) previously certified as free of transmission, ii) currently
51 endemic (pre-certification countries) and iii) requiring certification but which have not recorded a
52 case of the infection since the inception of the GWEP in the late 1980’s. We quantified the number
53 of conflict events and rates per 100,000 population for the most recent years, highlight the main
54 types of conflict and the main actors responsible, as well as present specific data from Chad and Mali
55 as case studies.

Methods

Study area

The cross-sectional study included sub-Saharan African countries that were categorised as those in the pre-certification stage and those in the post-certification stage.

Pre-certification countries included those currently endemic for dracunculiasis, namely Angola, Chad, Ethiopia, Mali and South Sudan (from 2011 Independence onwards), and countries with historical evidence of Guinea worm but are yet to be certified as free from dracunculiasis, including the DRC and Sudan.

Post-certification countries included Benin, Burkina Faso, Cameroon, CAR, Cote d'Ivoire, Ghana, Kenya, Mauritania, Niger, Nigeria, Senegal, Togo and Uganda. The dates when these countries were certified free of transmission are provided in Molyneux et al..[5] See Figure 1 for the map of pre-certification and post-certification countries which cover vast geographical regions of sub-Saharan Africa covering more than 15 million square kilometres (km²)[25] with poor accessibility to urban centres or cities.[26] The land area of each country is shown in Table 1 with Angola, Chad, DRC, Mali, Niger and Sudan more than 1.2 million km² in size.

Figure 1. Map of pre-certification and post-certification countries in sub-Saharan Africa

Data sources

To examine Guinea worm status in relation to spatial and temporal distribution of conflict events and regional access within each country, several data sources were obtained;

- Guinea worm information was based on World Health Organisation (WHO) annual reports and Dracunculiasis Eradication Portal,[2,15,27] and GWEP reports by The Carter Centre and the Centres for Disease Control and Prevention.[3,8]
- Conflict data were downloaded from the Armed Conflict Location and Event Data Project (ACLED),[28,29] including geo-referenced location data on conflict event types categorised as battles, riots, protests, strategic developments, explosions/remote violence and violence against civilians and actors i.e. groups of people or organisations reported to be responsible for the events (definitions available on ACLED website)[29] for the period from January 2000 to October 2020.
- Population data were obtained from the World Bank databank and based on 2019 estimates.[25]

- Administrative boundary information was obtained from the United Nations Office for the Coordination of Humanitarian Affairs (OCHA).[30]
- Accessibility information was based on regional distance (kilometres (kms)) to the capital city and from modelled maps of 'Accessibility to cities', quantified as travel time in minutes (converted to hours) to the nearest high-density urban centre or city at a resolution of 1 x 1 km for 2015.[26]

These data sources represent the best available in the public domain, and it is acknowledged that there may be some missing cases and conflict event data, and differences in population estimates, country size and accessibility compared with other sources.

Patient and public involvement

No patient was included in this study.

Data analysis and mapping

Conflict and population data were downloaded, and collated, tabulated and graphed in Microsoft Excel (Microsoft Corporation, Redmond, WA) and the administrative boundary and accessibility to cities data were downloaded and imported into geographical information software (GIS) ArcGIS 10.7 (ESRI, Redlands, Ca) for mapping using the available GPS coordinates and descriptive analysis.

First, the number of conflict events for the pre-certification and post-certification countries were summarised for years from 2000 to 2020 to highlight long-term temporal trends and high-conflict Guinea worm countries.

Second, the overall number of conflict events and rates per 100,000 population for the most recent years, 2018 to 2020, were quantified for each country. The different types of conflict events were tabulated and mapped, and the countries with the most events and highest rates per population were identified as high-conflict countries. The main actors reported to be responsible for the highest number of events in the high-conflict countries were summarised.

Finally, the situation in Chad and Mali since 2018 was presented as contrasting case studies, and included a summary and maps of the number of Guinea worm human and/or animal cases and regions affected; the number of conflict events types and main actors in each region; and accessibility of each region measured as the distance (kms) between the centre of each region and

each capital city using the Measure tool in ArcGIS, and the average time (hours) of each region to high-density urban centre or city based on data extracted using the Zonal Statistics tool in ArcGIS.

Results

Overall summary 2010-2020

The total number conflict events reported for pre-certification and post-certification countries between 2000-2020 is shown in Figure 2A and 2B (data available in Supplementary file 1). Overall, the temporal trends in conflict events across all countries were similar with a marked increase from 2010 onwards.

In the five endemic countries, a total of 18,895 conflict events were reported between 2000-2020 with the highest numbers in South Sudan (n=6986 from 2011 onwards) representing 37.0% of the total. In the first decade between 2000-2010, a total of 2437 events were reported, which increased 6.8-fold to 16,458 events between 2011-2020, with 41.5% reported in the last three years since 2018. In the two countries yet to be certified, a total of 30,805 events were reported with the highest numbers in DRC (n=17,385; 56.4%). Between 2000-2010, a total of 6387 events were reported, which increased 3.8-fold to 24,418 events between 2011-2020, with 41.5% reported in the last three years.

In the post-certification countries, a total of 48,615 events were reported with the highest numbers in Nigeria (n= 17,763) representing 36.5% of the total. In the first decade between 2000-2010, the 10,244 events were reported, which increased 3.7-fold to 38,371 events between 2011-2020, with around one third (37.3%) reported in the last three years.

Figure 2. Number of conflict events reported in pre-certification and post-certification countries between 2000 – 2020

Summary of conflict events in recent years 2018 – 2020

Pre-certification countries

In the five endemic countries where transmission of *D. medinensis* is ongoing, an overall total of 6,832 conflict events were reported between 2018-2020 (Table 1A; Figure 3). The highest numbers and rates per 100,000 population were reported in Mali (n=2556; 13.0 per 100,000) and South

1
2
3 Sudan (n=2143; 19.4 per 100,000). Overall, the most frequently reported events included violence
4 against civilians (n=2373), protests (n=993), and battles (n=2055) with South Sudan reporting the
5 highest number violence incidents against civilians (39.1% of total) and battles (46.4%) and Ethiopia
6 reporting the highest number of protests (49.8%). South Sudan also reported the highest rates of
7 violence against civilians (8.4 per 100,000), and battles (8.6 per 100,000), and Mali the highest rates
8 of protests (1.3 per 100,000). A summary of the actors reported to be responsible for the highest
9 number and type of conflict events in the high-risk countries is shown in Table 2A. For Mali, the
10 actors reported for the most events included JNIM: Group for Support of Islam and Muslims (n=661);
11 Unidentified Armed Group (Mali) (n=434) and Protesters (n=261). For South Sudan, the actors
12 included the Military Forces of South Sudan (2011-) (n=543), Unidentified Armed Group (South
13 Sudan) (n=399) and the Sudan People's Liberation Movement-In Opposition (n=157).

21
22
23 In DRC and Sudan (two countries where transmission has not been reported recently but required to
24 be certified), a total of 10,139 events were reported between 2018-2020 (Table 1B; Figure 3). The
25 highest number and rate per 100,000 population were reported in DRC (n=7016; 8.1 per 100,000).
26 The most frequently reported events included violence against civilians (n=3242) protests (n=2656),
27 and battles (n=2628) with DRC reporting the highest number of these events representing 76.6%,
28 38.6% and 86.2% of the total respectively. The DRC also reported the highest rates of violence
29 against civilians (2.9 per 100,000) and battles (2.6 per 100,000), and Sudan the highest rates of
30 protests (3.8 per 100,000). A summary of the actors reported to be responsible is shown in Table
31 2A. The main actors associated with the two most reported events in both countries included an
32 Unidentified Armed Group (DRC=1236; Sudan =233), and Protesters (DRC=975; Sudan=1590).

Post-certification countries

In the post-certification countries, a total of 18,146 events (3.9 per 100,000) were reported between 2018-2020 (Table 1B; Figure 3). The highest numbers reported were in Nigeria (n=6903), Cameroon (n=2517), Burkina Faso (n=2004), and the highest rates in CAR (26.4 per 100,000), Burkina Faso (9.9 per 100,000) and Cameroon (9.7 per 100,000). The most frequently reported events included violence against civilians (n=5803) protests (n=4023), and battles (n=3891) with Nigeria reporting the highest number of these events representing 38.3%, 43.4% and 42.5% of the total respectively. The CAR reported the highest rates of battles (7.4 per 100,000), and violence against civilians (9.7 per 100,000), and Mauritania the highest number of protests (8.5 per 100,000).

A summary of the actors reported to be responsible for the highest number and type of conflict events in the high-risk countries is shown in Table 2B. For Nigeria, the actors associated with the two most reported events included Protesters (Nigeria) (n=1735) and an Unidentified Armed Group (n=1033). For Cameroon, the actors included the Islamic State (West Africa) and/or Boko Haram - Jamatu Ahli is-Sunnah lid-Dawatai wal-Jihad (n= 817) and Military Forces of Cameroon (1982-) (n=642). For CAR, the actors included an Unidentified Armed Group (CAR) (n=271) and the UPC: Union for Peace in the Central African Republic (n=155). For Burkina Faso, the actors included JNIM: Group for Support of Islam and Muslims and/or Islamic State (Greater Sahara) (n=455) and JNIM: Group for Support of Islam and Muslims (n= 340).

Chad case study

The capital N'Djamena and six regions reporting Guinea worm human cases and/or animal infections between 2018 and 2020 are shown in Figure 4A and 4 B, together with the conflict event types reported in Chad, and the neighbouring pre-certification country of Sudan and post-certification countries of Cameroon, CAR and Niger.

Guinea worm situation. Human disease cases were reported in 2018 (n=17), 2019 (n=48) and 2020 (n=13). The areas affected included the Chari Baguirmi region, in Bailli (2018; 2019), Bousso (2018; 2019; 2020), Dourbali (2019), Kouno (2019) and Mandelia (2018; 2020) districts; the Moyen Chai region, in Danamadji (2019), Korbal (2018; 2019) Kyabe and Sahr (2018; 2019; 2020) districts; the Salamat region, in Aboudeia (2018; 2019; 2020), Amtiman (2018; 2019) and Haraze (2019); the Tanjile region in Bere district (2018) and the Wadi-Fira region in Matadjana district (2020).

1
2
3 Animal infections, predominately domesticated dog infections were high and reported in 2018
4 (n=1040), 2019 (n=1935) and 2020 (n=1464). The areas affected included the capital N'Djamena
5 (2018) and the Chari Baguirmi (2018; 2019), Mandoul (2018), Moyen Chai (2018; 2019), Mayo-Kebbi
6 Est (2018; 2019) and Salamat (2018; 2019) regions (Figure 4B).
7
8
9

10
11 Conflict events. The highest number of conflict events was reported in N'Djamena (n=104) (Table
12 3A), were predominately protests (44 events) with protestors reported as the main actors. In the
13 other Guinea worm affected regions, the number of conflict events was lower and ranged from 0 -
14 13 events in 2018-2020. The main conflict event type in the Chari-Baguirmi region was of violence
15 against civilians (3 events) with Military Forces, Police Forces and Moile Communal Militia the main
16 actors; in Moyen-Chari was battles (2 events; Unidentified Communal Militia Chad); in Salamat was
17 battles (2 events; Nomad and National Guard and Unidentified Communal Militia); in Tanjili was
18 battles (10 events; Fulani Militia, Koutoune Communal Militia; Tandjile Communal militia and
19 Unidentified Armed Group); and in Mayo-Kebbi Est was violence against civilians (4 events; Nomad
20 and National Guard, Military Forces, Unidentified Armed Group (Cameroon and Chad)).
21

27
28

29 Regional access. The level of access in terms of distance (kms) to the capital N'Djamena and
30 accessibility to a city in hours within Chad and in relation to Guinea worm status and conflict events
31 is shown in Table 3A. Of the Guinea worm affected regions, Salamat (600-700kms) was the furthest
32 from the capital and had the longest estimated time of 10 hours to the nearest city. Of the northerly
33 non-endemic regions, the Lac (n=88), Quadd (n=57) and Tibesti (n=55) had the highest number of
34 conflict events, with Tibesti (900-1000km) the furthest distance and had the longest estimated time
35 of 42.1 hours to the nearest city.

45 *Mali case study*

46
47 The capital Bamako and two regions reporting Guinea worm animal infections in 2018-2020 are
48 shown in Figure 4C and 4D, together with the conflict event types reported in Mali, and the
49 neighbouring pre-certification countries of Burkina Faso, Niger and Mauritania.
50
51
52
53

54 Guinea worm situation. One human case was reported in early 2020 – the first human case reported
55 since 2015. Animal infection, predominately domesticated dog infections were reported in 2018
56 (n=18), 2019 (n=8) and 2020 (n=9). The areas affected included the Mopti region, in Djenne (2018;
57
58
59
60

1
2
3 2019; 2020) district, and the Segou region in Markal (2018), Tominian, Macina (2018; 2019; 2020)
4 and Baroueli (2020) districts (Figure 4D).
5
6

7
8 Conflict events. The highest number of conflict events was reported in Mopti region (n=1206) (Table
9 3B), predominately violence against civilians (561 events) and battles (347 events) with Fulani Ethnic
10 Militia, Groups for Support of Islam and Muslims, Unidentified Armed Group and/ or Military Forces
11 reported as the main actors associated with these events. The main conflict events in the Segou
12 region were battles (55 events) and violence against civilians (44 events) with Group for Support of
13 Islam and Muslims reported as the main actors associated with battles and Military Forces of Mali
14 and Dozo Communal Militia main actors for violence against civilians.
15
16
17
18
19

20
21 Regional access. The level of access in terms of distance to the capital Bamako and accessibility to a
22 city in hours within Mali and in relation to case status and conflict events is shown in Table 3B. Of
23 the Guinea worm affected regions, Mopti was the furthest from the capital Bamako, approximately
24 500-600 km, and had the longest accessibility time of 4.1 hours to the nearest city. Of the
25 unaffected regions, Gao (n=503), and Tombouctou (n=264) had the highest number of conflict
26 events, with Gao (1000-1100kms) the furthest away from the capital, and Tombouctou the longest
27 estimated time of 62.9 hours to the nearest city.

Discussion

The GWEP has made remarkable progress since activities began in the late 1980's with the WHO reporting only tens of human cases in recent years. [15,27] This success has been driven by country commitment, the support from the WHO[2] and The Carter Center[3] and articulating the fundamental public health interventions to eliminate the transmission - case containment, control of copepods, access to safe drinking water (including filtration), regular reporting and surveillance, and instituting a reward system and the follow up of rumours.[5,7]

This paper, however, documents that over the past two decades, the numbers of incidents of conflict and violence have increased dramatically, especially in the last 3 years since 2018. This is not only of concern for endemic countries, but for the two countries yet to be certified, and the 13 countries that were previously endemic for the infection requiring ongoing surveillance.[2] The Guinea worm community have increasingly recognised that certification will face the challenges of acquiring comprehensive and reliable information in conflict zones and in accessing areas where national governments have limited control.[5,8,15] In addition, the porosity of international borders, extensive migration generated by insecurity, inter-country range of many of the actors responsible for violence, and the need for these geographically vast countries to ensure that any Guinea worm case is recognised and reported, highlights the immense challenges programmes face to satisfy the criteria for certifying the absence of transmission and the effectiveness of surveillance.[6]

The characteristics of the situation in areas of West and Central Africa are that there are many groups who are responsible for violence at both national and local levels and their motivations are different, even within the same region.[28,29] Understanding how these challenges for the GWEP can be overcome is essential if the country elimination objective and global eradication certification is to be achieved. Providing detailed data, as described in this paper, is necessary so risk assessments can be made to safely operationalise field work, especially in remote locations where access is limited.[20,31] This underscores the value of understanding the spatial and temporal patterns of conflict, identifying hotspots, the actors responsible and their sphere of influence. This information will allow the potential impact of violence on GWEP activities to be assessed consonant with the need to satisfy the robust criteria established by WHO a country to be certified by the ICCDE based on the information in the detailed national report submitted to WHO, and on which the ICT to base their assessments on the likelihood of the country being free of *D. medinensis* transmission. WHO and the Carter Center should avail itself of the real-time data available from ACLED to evaluate the challenges and risks to programme staff and in planning certification missions, WHO, should seek to acquire Guinea worm relevant information from areas designated to be of high security risk by

1
2
3 country UN Security Advisors as innovative means of acquiring the necessary information for
4 certification will be required.
5
6

7 We have summarised in detail the magnitude, geographical extent and increasing incidence of
8 conflict and violence in those countries where Guinea worm remains a problem for those
9 responsible for ensuring a successful endgame for eradication, which now has a target of 2030 for
10 global certification.[4] The scale of the challenge can probably best be illustrated by the fact that
11 the total area of pre-certification countries is similar to continental USA.[25] This WHO NTD Road
12 Map target implies that all countries that remain to be certified must have zero cases in humans and
13 animals by 2026/7 as a minimum of three years of zero global cases must be reported
14 over the period 2027- 2030. This will require intense integrated human and animal surveillance, in
15 countries at present suffering conflict events, with a trend that is regrettably accelerating rather
16 than diminishing. The Chad and Mali case studies highlight the multifaceted epidemiological and
17 conflict situations, the challenging access and safety issues, which will require bespoke risk
18 assessments and innovative strategies to reach certification. A One Health approach including
19 human, animal and environmental components should be considered given the evolving modes
20 transmission,[32,33] taking the cost-effectiveness[34] and conflict context into account.

31 The case and conflict event data used in this study are valuable resources to use as a first step in
32 assessing a situation. However, as there are some limitations with using secondary data, it will be
33 important to supplement this information with details from local, reliable sources and trusted
34 partners on the ground, this may help to determine the actors motivations and identify areas that
35 are considered "secure". Further, it will be important that local GWEP staff have data management
36 and analytical skills to access, download, examine, summarise and map the data in a meaningful way
37 to inform the programmes. Mapping skills may be developed using user-friendly open sources GIS
38 software such as QGIS (www.qgis.org), which is free to download, has many available online training
39 tutorials available and a range of analytical tool that can produce the same results as presented in
40 this paper.

47
48

49 The methodology and tools we have used in this paper provide a better understanding of the
50 challenges the GWEP faces and are based on the recent studies undertaken to understand and
51 address the risks for other NTD programmes.[35] These should be more widely promoted not only
52 for Guinea worm, but as a management and risk assessment tool for other research and health
53 programmes working in areas and countries of complex emergencies and insecurity.

Contributors

LAKH and DHM conceptualised the paper. LAKH accessed data sources, applied analytical methods and produced the maps. Both authors contributed to the data interpretation, writing the first and final version of the manuscript.

Funding

No specific grant was obtained for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests

LAKH declares no competing interests. DHM is a member of the International Commission for the Certification of Dracunculiasis Eradication

Patient and public involvement Patients and/or the public were not involved in the design, or conduct, or reporting, or dissemination plans of this research.

Data availability statement

All data are available in the paper, supplementary file and accessible from the public data sources.

Ethical Approval

No ethical approval was necessary for the paper as it does not involve work on human or animal subjects or experimental work and is based on using analysis of data available in the public domain.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	6-7
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6-7
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6-7
Bias	9	Describe any efforts to address potential sources of bias	6-7
Study size	10	Explain how the study size was arrived at	6-7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	7
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	N/A
		(b) Describe any methods used to examine subgroups and interactions	6-7
		(c) Explain how missing data were addressed	N/A
		(d) If applicable, describe analytical methods taking account of sampling strategy	N/A
		(e) Describe any sensitivity analyses	N/A
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	8-10
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	N/A
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	8-12
		(b) Indicate number of participants with missing data for each variable of interest	N/A
Outcome data	15*	Report numbers of outcome events or summary measures	8-12
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	N/A

		(b) Report category boundaries when continuous variables were categorized	8-12
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	11-12
Discussion			
Key results	18	Summarise key results with reference to study objectives	13
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	13-
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	13-14
Generalisability	21	Discuss the generalisability (external validity) of the study results	13-14
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	N/A

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
