## Abstract

### Purpose:

The substantial economic burden of work-related injury and illness, borne by workers, employers and social security programs, is primarily attributed to the durations of work disability among workers whose recovery requires a period of absence from work, with the majority of costs arising from the minority of workers with the longest duration absences. The objective of the Ontario Life after Workplace Injury Study (OLAWIS) is to describe the long-term health and labour market outcomes of workers disabled by work injury or illness after they are no longer receiving benefits or services from the work disability insurance authority.

### Participants:

Workers disabled by a work-related injury or illness were recruited from a sample frame of disability benefit claimants with over-sampling of claimants with longer benefit durations. Characteristics of workers, their employers and claimant benefits were obtained from baseline administrative data. Interviews completed at 18 months post-injury (T1) and to be completed at 36 months (T2) measure return-to-work and work status; income; physical and mental health; case manager and healthcare provider interactions; employer accommodations supporting return-to-work and socio-demographic characteristics. Of eligible claimants, 40% (1,132) participated in the T1 interview, with 96% consenting to participate in the T2 interview.

### Findings to date:

Preliminary descriptive analyses of T1 data have been completed. The median age was 50 and 56% were male. At 18 months following injury, 61% were employed by their at-injury employer, 16% had changed employment and 23% were not working. Past-year prescription opioid use was prevalent (34%), as was

1  
2  
3 past-year cannabis use (31%). Longer duration claimants had poorer function, recovery and health, and  
4  
5 more adverse labour market outcomes.  
6  
7

8 Future plans:  
9

10  
11 Multivariate analyses to identify modifiable predictors of adverse health and labour market outcomes  
12  
13 and a follow up survey of 96% of participants consenting to follow-up at 36 months are planned.

### Strengths and Limitations of this study

This longitudinal study collected information from workers disabled by a work-related injury or illness 18 and 36 months following the beginning of an episode of work disability.

This large, representative sample will inform understanding of the long-term consequences to health and labour force participation among an important sub-group of workers who experience long durations of work disability.

As eligibility criteria for participation in this cohort was restricted to disability due to a work-related injury or illness, the many other health conditions that can result in work disability are not represented in this cohort.

## Introduction

The burden of work-related injury and illness among workers in the developed economies is substantial.

Among working-aged adults, 1 of every six injuries requiring medical attention are caused by work exposures<sup>(1)</sup> with approximately 35% of these work-related injuries and illnesses resulting in periods of disability and work absence. An important minority of work injury or illness results in some degree of permanent impairment. For example, in a representative sample of Canadian adults, 25% of adults with disabilities attributed the underlying impairment to an exposure at work.<sup>(2)</sup>

The economic burden of work-related injury and illness borne by workers, employers and social security programs, is also substantial.<sup>(3)</sup> Much of this economic cost is attributed to the durations of work disability among workers whose recovery requires a period of absence from work. In addition to the economic costs attributed to compensation for lost income during the period of work absence, there is compelling evidence for long-lasting adverse impacts of work disability episodes on injured workers' subsequent labour force participation and labour market earnings.<sup>(4, 5)</sup>

While the durations of work disability are relatively short for the majority of work absence episodes, for an important minority of episodes, disability durations can be long, may result in loss of employment and are responsible for the majority of work disability insurance program expenditures. Understanding the factors that influence the duration of work disability episodes has been informed by research focused on four primary domains: characteristics of the injury and the worker, the nature of workplace accommodations to support workers returning to work, access to and the appropriateness of health care, and the influence of benefit policies established by work disability insurance providers.

Longitudinal cohort studies of injured workers have documented the role of injury severity, persistent pain, mental health impairments, older age, and recovery expectations as determinants of long duration disability episodes.<sup>(6-9)</sup> Understanding the influence of employer accommodation practices on disability

1  
2  
3 episode has been informed both by observational cohort studies, and by experimental study designs  
4  
5 involving randomized controlled trials.(10-16) Quasi-experimental study designs have advanced  
6  
7 understanding of the influence of disability insurance provider policies on the durations of work  
8  
9 disability.(16-19)  
10

11  
12 The contributions of this literature has led to important reforms to workplace and disability insurer  
13  
14 practices in many jurisdictions. However, there has been less attention focused on describing the  
15  
16 experiences of workers disabled by a work-related injury or illness over longer follow-up periods, or  
17  
18 adequately powered comparisons between the experiences of workers' compensation claimants with  
19  
20 long wage replacement durations compared to claimants with shorter durations. The objective of the  
21  
22 Ontario Life after Workplace Injury Study (OLAWIS) is to describe the long-term outcomes of workers  
23  
24 disabled by work injury or illness. The study design oversampled disability benefit recipients with longer  
25  
26 duration disability episodes and incorporates measures obtained at baseline from administrative records  
27  
28 with measures obtained from interviews with study subjects 18 months and 36 months following the  
29  
30 incidence of disabling injury or illness.  
31  
32  
33  
34  
35

36 In designing this study, we expected that poor health recovery outcomes at 18 and 36 months will be  
37  
38 more common among women, workers aged 50 or older, workers experiencing more severe traumatic  
39  
40 injury or non-traumatic musculoskeletal disorders and those using opioid medications. In parallel, we  
41  
42 hypothesized that shorter durations of wage replacement benefits will be more common among  
43  
44 workers who report early employer contact and who report an employer offer of accommodation. In  
45  
46 terms of labour market outcomes, we expected that a return to work with the at-injury employer will be  
47  
48 more common among workers with longer pre-injury employment tenure, workers who are union  
49  
50 members and workers with a positive perception of employment security. Poor labour market outcomes  
51  
52 at 18 and 36 months will be more common among workers with low educational attainment, workers  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 who have recently immigrated to Canada and workers with high symptom scores for pain and poor  
4  
5 mental health.

## 11 **Cohort description**

### 14 **Setting**

16  
17 In 2018, there were approximately 6.5 million labour force participants in Ontario, Canada. The majority  
18  
19 of employers in Ontario (approximately 70%) have a mandatory obligation to obtain work disability  
20  
21 insurance coverage from the publicly administered, single-payer workers' compensation insurance  
22  
23 authority, the Workplace Safety & Insurance Board (WSIB). Employers also have a legislated obligation  
24  
25 to accommodate employees with health impairments, including the duty to accommodate employees  
26  
27 who have experienced a work-related injury or illness. The WSIB administers benefits to entitled  
28  
29 workers, covering medical care services and provides wage replacement benefits for workers whose  
30  
31 recovery from a work-related injury or illness requires absence from work. In 2018, the WSIB  
32  
33 administered benefits for 160,000 compensation claims, of which 48,000 were claims resulting in lost-  
34  
35 time from work. The WSIB also schedules employer insurance premiums that incorporate financial  
36  
37 incentives to encourage early return-to-work practices by employers.  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

### 48 **Baseline recruitment**

49  
50  
51 Study sample recruitment was conducted between June 2019 and March 2020. WSIB administrative  
52  
53 records were used to identify with workers who had registered a compensation claim for wage  
54  
55 replacement benefits due to a physical injury or illness approximately 18 months prior.  
56  
57

1  
2  
3 To ensure adequate representation of participants with more serious and complex claims in the cohort,  
4 the OLAWIS sampling plan specified that approximately 400 participants were to be recruited in each of  
5 three compensation duration sample groups: short duration, i.e., 5 days to 3 months; medium duration,  
6 i.e., 3 to 12 months; and longer duration, i.e., 12+ months. We excluded lost-time claimants with benefit  
7 durations of less than 5 days. These claimants represented approximately 30% of all lost-time claimants.  
8  
9 The short duration sample represented 54% of all lost-time claimants, the medium duration sample  
10 represented 9% of all lost-time claimants and the longer duration sample represented 6% of all lost-time  
11 claimants. The rationale for recruiting three equal-sized samples of claimants, stratified by claim  
12 duration and complexity, was to obtain sufficient statistical power to identify claimant characteristics  
13 that meaningfully differ between the more frequent short-duration claimant profile and the less  
14 frequent long-duration claimant profile. A sample of 400 respondents in each group has the power to  
15 estimate statistically significant relative risks of 2.0 or greater for measures with prevalence of 10-20% (a  
16 prevalence difference of 5% in one group and 10% in a second group) and can detect relative risks of  
17 1.5% for measures with an average prevalence of 20% or greater (a difference of 13% in one group and  
18 20% in a second group).

19  
20 Records for 9,745 lost-time claimants were randomly selected by representatives of the WSIB to meet  
21 quota targets specified by the OLAWIS research team. WSIB representatives contacted claimants by  
22 telephone to obtain monthly quotas of claimants consenting to share their contact information with the  
23 OLAWIS research team. Lost-time claimants with a primary psychological injury, who were in the  
24 survivors program or serious injury program, who had a traumatic head injury resulting in  
25 communication impairment, younger than age 18, or who could not conduct an interview in English or  
26 French were excluded.

27  
28 Of the 2,816 claimants contacted, a total of 1,674 (59.4%) agreed to share their contact information. Of  
29 the claimants consenting, the survey services contractor was unable to establish contact with 385  
30  
31  
32  
33  
34  
35

1  
2  
3 claimants, received 125 interview refusals, 32 claimants were deemed ineligible and interviews were  
4 completed with 1,132 claimants (40.1% of eligible claimants and 87.7% of eligible claimants successfully  
5 contacted). Figure 1 shows the flow of participants.  
6  
7  
8

9  
10 Among participants, 358 (31.6%) were in the short duration claim sample, 374 (33.0%) were in the  
11 medium duration claim sample, and 400 (35.3%) were in the long duration claim sample. In this cohort  
12 of 1,132 claimants, 96% consented to be re-contacted for the 36-month follow-up survey and 94% gave  
13 permission to the research team to access information recorded in their WSIB administrative record.  
14  
15  
16  
17

18 Analyses were conducted comparing the 1,132 interview participants to consenting claimants who did  
19 not complete an interview and to the randomly selected recruitment sample. No substantive differences  
20 were observed between samples based on age, gender, geographic location, industry, and employer  
21 size. However, duration of benefits were slightly longer among participants vs non-participants (details  
22 available upon request).  
23

### 31 **Patient and public involvement**

32 Patients and the public were not involved in the design, conduct, reporting or dissemination plans of this  
33 research.  
34  
35  
36  
37  
38  
39

### 40 **Data collection**

41 Primary outcome measures and potential predictors of the primary outcomes were drawn from two  
42 sources; WSIB administrative records and an interviewer-administered questionnaire. Information  
43 available from administrative records of work disability insurance benefits was integrated with the  
44 information obtained from an interviewer-administered questionnaire. With participant's consent,  
45 information obtained from administrative records included measures of the nature of injury and injury  
46

5 economic sector.  
6  
7

### 8 **Interview-administered questionnaire: 18 months**

9

10  
11 Questionnaire measures were grouped in the following topic domains: (1) Return-to-work and labour  
12 market status; (2) function, recovery and measures of physical and mental health; (3) interactions  
13 between the claimant and the work disability insurance case managers; (4) interactions between the  
14 claimant and their healthcare providers; and (5) basic socio-demographic characteristics and pre-injury  
15 information on occupation, industry and workplace size. Relevant measures administered in previous  
16 cohort studies of disabled workers(12, 20) and measures administered in the Canadian Community  
17 Health Survey(21) were incorporated in the OLAWIS questionnaire when available. The interviews  
18 conducted by the survey services contractor lasted approximately 40 minutes and participants were  
19 remunerated \$40 CAD.

25  
26  
27  
28  
29  
30

#### 31 *1. Return-to-work and labour market status*

32  
33

34  
35 Respondents were asked whether they were currently working with their pre-injury employer and were  
36 asked a series of questions about interactions with the workplace where the injury occurred during the  
37 period of recovery and return-to-work. The questionnaire included items related to the frequency and  
38 quality of communication with the workplace, the nature of modified duties or accommodations  
39 proposed by the workplace, and perceptions of the outcome of the return-to-work experience. For  
40 employed respondents not currently working with their pre-injury employer, information was collected  
41 on the main reason they were not working with their pre-injury employer. For respondents not currently  
42 working, information was collected on whether they had made a return-to-work attempt and their  
43 perception of the main reason they were not currently working.  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54

#### 55 *2. Function, recovery and measures of physical and mental health*

56  
57

1  
2  
3 The questionnaire included a range of measures of function, recovery and health outcomes. Current  
4  
5 intensity of pain was measured by the Chronic Pain Grade Scale and pain-related interference with  
6  
7 normal activities was assessed.(22) Measures of self-rated health status and self-rated mental health  
8  
9 status(23-27) were administered along with the SF-12 scale(28) and the Kessler-6 screening tool for  
10  
11 mental disorder symptoms.(29) The questionnaire included a series of items used in the Canadian  
12  
13 Community Health Survey(21) to assess perceptions of work stress, life stress and life satisfaction, sleep  
14  
15 quality, alcohol consumption, and medication use. Questions were also included on current cannabis  
16  
17 use and if use was for therapeutic purposes.  
18  
19

### 20 21 22 *3. Interactions between the claimant and the work disability insurance case managers*

23  
24 Respondents were asked to assess the quality of interactions with work disability insurance case  
25  
26 managers, both in terms of interpersonal treatment and the quality of the information provided by case  
27  
28 managers.(11, 30)  
29  
30

### 31 32 *4. Interactions between the claimant and their healthcare providers*

33  
34 The questionnaire included items documenting the respondent's main health care provider, whether  
35  
36 difficulty was experienced accessing health care services, whether the use of health care services was  
37  
38 stressful and the respondent's assessment of the clarity of advice provided by health care providers  
39  
40 concerning returning to work.  
41  
42  
43

### 44 45 *5. Socio-demographic characteristics and pre-injury information on occupation, industry and workplace* 46 47 *size*

48  
49 The interview collected information on claimant age, sex, immigrant status, educational attainment,  
50  
51 family structure, union membership, pre-injury occupational tasks and work hours, workplace size and  
52  
53  
54  
55  
56  
57

1  
2  
3 industry of employment. Respondents also provided information about the amount of personal and  
4  
5 household income in the previous 12 months, and their current main income sources.  
6  
7  
8  
9

### 11 **Interview-administered questionnaire: 36 months**

12  
13  
14 Participants who agreed to be re-contacted will be administered an abbreviated version of the 18 month  
15  
16 questionnaire, retaining topic domains concerning; 1) current labour market status, 2) function,  
17  
18 recovery and measures of physical and mental health and 3) basic socio-demographic characteristics. An  
19  
20 extended questionnaire domain pertaining to cannabis use will be administered to participants  
21  
22 reporting current cannabis use at the 18 month interview. The 36 month interview will be administered  
23  
24 over the period January to December 2021.  
25  
26  
27  
28  
29  
30

### 31 **Findings to date**

32  
33  
34 Unweighted descriptive analyses completed to date are summarized in Table 1 and Table 2. The median  
35  
36 age at the time of the baseline interview (approximately 18 months after injury) was 50; participants in  
37  
38 the short duration sample had a median age of 47, whereas those in the long duration sample had a  
39  
40 median age of 51. Over half of the participants (56%) were male. The most common industries were  
41  
42 health care and social assistance (15%), construction, utilities and mining (14%), and transportation and  
43  
44 warehousing (13%), and manufacturing (13%), with significant differences in industry composition  
45  
46 across claim duration groups ( $p=0.003$ ). Approximately 40% of the sample had a household income  
47  
48 greater than \$100,000 without a significant difference in income across claim duration groups.  
49  
50  
51 Participants with the longest claim durations had lower education and were less likely to be presently  
52  
53 working. They were also more likely to have suffered a head injury, to currently be receiving services  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 from the WSIB, to be receiving health care for the treatment of conditions related to the work injury, to  
4  
5 have pain symptoms, and to demonstrate greater health impairment on a range of measures.  
6  
7

8 Results regarding return-to-work with the at-injury employer are displayed in Table 3. Initially, 90% of  
9  
10 participants returned to their at-injury employer. Males, those in the longer claim duration sample,  
11  
12 those in smaller workplaces and those in rural areas were less likely to return to work with their at-  
13  
14 injury-employer. Union members and participants reporting a permanent employment arrangement at  
15  
16 the time of injury were more likely to return to work with their at-injury employer.  
17  
18

19  
20 Eighteen months following the work injury incident, 35% of participants reported that they were no  
21  
22 longer working for the at-injury employer (Table 4). Approximately 50% of these workers chose to  
23  
24 terminate employment and 20% reported the employer did not have work available. Approximately 14%  
25  
26 of participants reported that the employer had fired them or terminated the employment relationship  
27  
28 and approximately 10% of participants chose to retire.  
29  
30

### 31 32 **Strengths and limitations**

33  
34  
35 The Ontario Life After Work Injury Study cohort was designed to address two important limitations in  
36  
37 previous research examining the determinants of adverse health and labour market outcomes following  
38  
39 an episode of work disability—length of follow up, and sample size. In terms of the first, this study  
40  
41 follows a large, representative sample of workers who experienced a disabling work-related injury or  
42  
43 illness for a longer time period than has typically been reported in the current literature. Information  
44  
45 provided by claimants 18 months and 36 months following a disabling work injury will inform  
46  
47 understanding of the long-term consequences to health, function and labour force participation. In  
48  
49 terms of the second, the recruitment of adequate numbers of study participants with the longest  
50  
51 durations of work disability will provide sufficient statistical power to identify the modifiable and non-  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 modifiable characteristics of claimants associated with long disability durations, not typically possible in  
4  
5 an inception cohort.  
6  
7

8 This study is not without limitations. Although differences between participants and non-participants on  
9  
10 observed characteristics were minor, there may be important differences in unmeasured characteristics  
11  
12 which may have influenced participation. We also note that the eligibility criteria for participation in this  
13  
14 cohort was restricted to disability due to a work-related injury or illness. The many other health  
15  
16 conditions that can result in work disability are not represented in this cohort.  
17  
18

19  
20 Although not anticipated by the OLAWIS research team, the experiences of the longitudinal cohort  
21  
22 between the first and the second follow-up interviews will intersect with the COVID-19 public health  
23  
24 emergency. Nationally representative surveys conducted during the emergency found that 28% of  
25  
26 employed Canadians were concerned that they might lose their job or self-employment income as a  
27  
28 consequence of the emergency and 33% of respondents reported that the emergency would have a  
29  
30 major or moderate impact on their ability to meet financial obligations.(31) To respond to the acute  
31  
32 economic effects of the COVID-19 emergency on households and on employers, the Government of  
33  
34 Canada has rapidly implemented a range of financial relief programs that have the potential to provide  
35  
36 more than \$140 billion in direct support.(32) We anticipate that the economic, social and health impacts  
37  
38 of the unprecedented contraction in the Canadian labour market will have more substantive negative  
39  
40 impacts on workers with health impairments.  
41  
42  
43

44  
45 Over the past two decades, many jurisdictions in the developed economies have achieved important  
46  
47 reductions in the incidence of work-related injury and illness.(1, 33) Paralleling these achievements,  
48  
49 progress has also been made in reducing the burden of disability among workers experiencing a work-  
50  
51 related injury or illness. Research contributions can inform future innovations in workplace practices  
52  
53 and disability insurance provider policies to improve the prevention and management of work disability.  
54

2  
3 **Authors' contributions:** VN conducted data analysis, drafted the initial manuscript and approved the  
4 final manuscript as submitted. ET, NC, PS and CM contributed to the development of the study protocol  
5 and the acquisition of research funding. They each revised the manuscript critically for important  
6 intellectual content and approved the final manuscript as submitted. CM is the principal investigator for  
7 the study. He led the conceptualisation, development and design of the study.

## Abstract

### Purpose:

The substantial economic burden of work-related injury and illness, borne by workers, employers and social security programs, is primarily attributed to the durations of work disability among workers whose recovery requires a period of absence from work, with the majority of costs arising from the minority of workers with the longest duration absences. The objective of the Ontario Life after Workplace Injury Study (OLAWIS) is to describe the long-term health and labour market outcomes of workers disabled by work injury or illness after they are no longer receiving benefits or services from the work disability insurance authority.

### Participants:

Workers disabled by a work-related injury or illness were recruited from a sample frame of disability benefit claimants with over-sampling of claimants with longer benefit durations. Characteristics of workers, their employers and claimant benefits were obtained from baseline administrative data. Interviews completed at 18 months post-injury (T1) and to be completed at 36 months (T2) measure return-to-work and work status; income; physical and mental health; case manager and healthcare provider interactions; employer accommodations supporting return-to-work and socio-demographic characteristics. Of eligible claimants, 40% (1,132) participated in the T1 interview, with 96% consenting to participate in the T2 interview.

### Findings to date:

Preliminary descriptive analyses of T1 data have been completed. The median age was 50 and 56% were male. At 18 months following injury, 61% were employed by their at-injury employer, 16% had changed employment and 23% were not working. Past-year prescription opioid use was prevalent (34%), as was

1  
2  
3 past-year cannabis use (31%). Longer duration claimants had poorer function, recovery and health, and  
4  
5 more adverse labour market outcomes.  
6  
7

### Strengths and Limitations of this study

This longitudinal study collected information from workers disabled by a work-related injury or illness 18 and 36 months following the beginning of an episode of work disability.

This large, representative sample will inform understanding of the long-term consequences to health and labour force participation among an important sub-group of workers who experience long durations of work disability.

As eligibility criteria for participation in this cohort was restricted to disability due to a work-related injury or illness, the many other health conditions that can result in work disability are not represented in this cohort.

## Introduction

The burden of work-related injury and illness among workers in the developed economies is substantial.

Among working-aged adults, 1 of every six injuries requiring medical attention are caused by work exposures<sup>(1)</sup> with approximately 35% of these work-related injuries and illnesses resulting in periods of disability and work absence. An important minority of work injury or illness results in some degree of permanent impairment. For example, in a representative sample of Canadian adults, 25% of adults with disabilities attributed the underlying impairment to an exposure at work.<sup>(2)</sup>

The economic burden of work-related injury and illness borne by workers, employers and social security programs, is also substantial.<sup>(3)</sup> Much of this economic cost is attributed to the durations of work disability among workers whose recovery requires a period of absence from work. In addition to the economic costs attributed to compensation for lost income during the period of work absence, there is compelling evidence for long-lasting adverse impacts of work disability episodes on injured workers' subsequent labour force participation and labour market earnings.<sup>(4, 5)</sup>

While the durations of work disability are relatively short for the majority of work absence episodes, for an important minority of episodes, disability durations can be long, may result in loss of employment and are responsible for the majority of work disability insurance program expenditures. Understanding the factors that influence the duration of work disability episodes has been informed by research focused on four primary domains: characteristics of the injury and the worker, the nature of workplace accommodations to support workers returning to work, access to and the appropriateness of health care, and the influence of benefit policies established by work disability insurance providers.

Longitudinal cohort studies of injured workers have documented the role of injury severity, persistent pain, mental health impairments, older age, and recovery expectations as determinants of long duration disability episodes.<sup>(6-9)</sup> Understanding the influence of employer accommodation practices on disability

1  
2  
3 episode has been informed both by observational cohort studies, and by experimental study designs  
4  
5 involving randomized controlled trials.(10-16) Quasi-experimental study designs have advanced  
6  
7 understanding of the influence of disability insurance provider policies on the durations of work  
8  
9 disability.(16-19)  
10

11  
12 The contributions of this literature has led to important reforms to workplace and disability insurer  
13  
14 practices in many jurisdictions. However, there has been less attention focused on describing the  
15  
16 experiences of workers disabled by a work-related injury or illness over longer follow-up periods, or  
17  
18 adequately powered comparisons between the experiences of workers' compensation claimants with  
19  
20 long wage replacement durations compared to claimants with shorter durations. The objective of the  
21  
22 Ontario Life after Workplace Injury Study (OLAWIS) is to describe the long-term outcomes of workers  
23  
24 disabled by work injury or illness. The study design oversampled disability benefit recipients with longer  
25  
26 duration disability episodes and incorporates measures obtained at baseline from administrative records  
27  
28 with measures obtained from interviews with study subjects 18 months and 36 months following the  
29  
30 incidence of disabling injury or illness.  
31  
32  
33  
34  
35

36 In designing this study, we expected that poor health recovery outcomes at 18 and 36 months will be  
37  
38 more common among women, workers aged 50 or older, workers experiencing more severe traumatic  
39  
40 injury or non-traumatic musculoskeletal disorders and those using opioid medications. In parallel, we  
41  
42 hypothesized that shorter durations of wage replacement benefits will be more common among  
43  
44 workers who report early employer contact and who report an employer offer of accommodation. In  
45  
46 terms of labour market outcomes, we expected that a return to work with the at-injury employer will be  
47  
48 more common among workers with longer pre-injury employment tenure, workers who are union  
49  
50 members and workers with a positive perception of employment security. Poor labour market outcomes  
51  
52 at 18 and 36 months will be more common among workers with low educational attainment, workers  
53  
54 who have recently immigrated to Canada and workers with high symptom scores for pain and poor  
55  
56  
57  
58  
59  
60

1  
2  
3 mental health. Examination of these hypotheses will contribute to the international literature on the  
4  
5 impact of health impairments secondary to traumatic injury on labour force participation, and the role  
6  
7 of workplace accommodation in enabling employment participation among workers with health  
8  
9 impairments.  
10  
11  
12  
13  
14  
15

## 16 **Cohort description**

### 17 **Setting**

18  
19  
20  
21 In 2018, there were approximately 6.5 million labour force participants in Ontario, Canada. The majority  
22  
23 of employers in Ontario (approximately 70%) have a mandatory obligation to obtain work disability  
24  
25 insurance coverage from the publicly administered, single-payer workers' compensation insurance  
26  
27 authority, the Workplace Safety & Insurance Board (WSIB). Employers also have a legislated obligation  
28  
29 to accommodate employees with health impairments, including the duty to accommodate employees  
30  
31 who have experienced a work-related injury or illness. The WSIB administers benefits to entitled  
32  
33 workers, covering medical care services and provides wage replacement benefits for workers whose  
34  
35 recovery from a work-related injury or illness requires absence from work. In 2018, the WSIB  
36  
37 administered benefits for 160,000 compensation claims, of which 48,000 were claims resulting in lost-  
38  
39 time from work. The WSIB also schedules employer insurance premiums that incorporate financial  
40  
41 incentives to encourage early return-to-work practices by employers.  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

### 52 **Baseline recruitment**

1  
2  
3 Study sample recruitment was conducted between June 2019 and March 2020. WSIB administrative  
4 records were used to identify with workers who had registered a compensation claim for wage  
5 replacement benefits due to a physical injury or illness approximately 18 months prior.  
6  
7

8  
9  
10 To ensure adequate representation of participants with more serious and complex claims in the cohort,  
11 the OLAWIS sampling plan specified that approximately 400 participants were to be recruited in each of  
12 three compensation duration sample groups: short duration, i.e., 5 days to 3 months; medium duration,  
13 i.e., 3 to 12 months; and longer duration, i.e., 12+ months. We excluded lost-time claimants with benefit  
14 durations of less than 5 days. These claimants represented approximately 30% of all lost-time claimants.  
15  
16 The short duration sample represented 54% of all lost-time claimants, the medium duration sample  
17 represented 9% of all lost-time claimants and the longer duration sample represented 6% of all lost-time  
18 claimants. The rationale for recruiting three equal-sized samples of claimants, stratified by claim  
19 duration and complexity, was to obtain sufficient statistical power to identify claimant characteristics  
20 that meaningfully differ between the more frequent short-duration claimant profile and the less  
21 frequent long-duration claimant profile. Survey weights are applied for analyses that focus on  
22 representing the target population of claimants with durations of 5 days or longer. A sample of 400  
23 respondents in each group has the power to estimate statistically significant relative risks of 2.0 or  
24 greater for measures with prevalence of 10-20% (a prevalence difference of 5% in one group and 10% in  
25 a second group) and can detect relative risks of 1.5% for measures with an average prevalence of 20% or  
26 greater (a difference of 13% in one group and 20% in a second group).  
27  
28

29  
30  
31 Records for 9,745 lost-time claimants were randomly selected by representatives of the WSIB to meet  
32 quota targets specified by the OLAWIS research team. WSIB representatives contacted claimants by  
33 telephone to obtain monthly quotas of claimants consenting to share their contact information with the  
34 OLAWIS research team. Lost-time claimants with a primary psychological injury, who were in the  
35 survivors program or serious injury program, who had a traumatic head injury resulting in  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57

1  
2  
3 communication impairment, younger than age 18, or who could not conduct an interview in English or  
4  
5 French were excluded.  
6  
7

8 Of the 2,816 claimants contacted, a total of 1,674 (59.4%) agreed to share their contact information. Of  
9  
10 the claimants consenting, the survey services contractor was unable to establish contact with 385  
11  
12 claimants, received 125 interview refusals, 32 claimants were deemed ineligible and interviews were  
13  
14 completed with 1,132 claimants (40.1% of eligible claimants and 87.7% of eligible claimants successfully  
15  
16 contacted). Figure 1 shows the flow of participants.  
17  
18

19  
20 Among participants, 358 (31.6%) were in the short duration claim sample, 374 (33.0%) were in the  
21  
22 medium duration claim sample, and 400 (35.3%) were in the long duration claim sample. In this cohort  
23  
24 of 1,132 claimants, 96% consented to be re-contacted for the 36-month follow-up survey and 94% gave  
25  
26 permission to the research team to access information recorded in their WSIB administrative record.  
27  
28

29  
30 Analyses were conducted comparing the 1,132 interview participants to consenting claimants who did  
31  
32 not complete an interview and to the randomly selected recruitment sample. No substantive differences  
33  
34 were observed between samples based on age, gender, geographic location, industry, and employer  
35  
36 size. However, duration of benefits were slightly longer among participants vs non-participants (details  
37  
38 available upon request).  
39  
40

#### 41 **Patient and public involvement**

42  
43 Patients and the public were not involved in the design, conduct, reporting or dissemination plans of this  
44  
45 research.  
46  
47

#### 48 **Data collection**

49  
50 Primary outcome measures and potential predictors of the primary outcomes were drawn from two  
51  
52 sources; WSIB administrative records and an interviewer-administered questionnaire. Information  
53  
54  
55  
56  
57

1  
2  
3 available from administrative records of work disability insurance benefits was integrated with the  
4  
5 information obtained from an interviewer-administered questionnaire. With participant's consent,  
6  
7 information obtained from administrative records included measures of the nature of injury and injury  
8  
9 event, benefit duration, workers' occupation and geographic location and the employer size and  
10  
11 economic sector.  
12  
13

### 14 15 **Interview-administered questionnaire: 18 months**

16  
17  
18 Questionnaire measures were grouped in the following topic domains: (1) Return-to-work and labour  
19  
20 market status; (2) function, recovery and measures of physical and mental health; (3) interactions  
21  
22 between the claimant and the work disability insurance case managers; (4) interactions between the  
23  
24 claimant and their healthcare providers; and (5) basic socio-demographic characteristics and pre-injury  
25  
26 information on occupation, industry and workplace size. Relevant measures administered in previous  
27  
28 cohort studies of disabled workers(12, 20) and measures administered in the Canadian Community  
29  
30 Health Survey(21) were incorporated in the OLAWIS questionnaire when available. The interviews  
31  
32 conducted by the survey services contractor lasted approximately 40 minutes and participants were  
33  
34 remunerated \$40 CAD.  
35  
36

#### 37 38 39 *1. Return-to-work and labour market status*

40  
41 Respondents were asked whether they were currently working with their pre-injury employer and were  
42  
43 asked a series of questions about interactions with the workplace where the injury occurred during the  
44  
45 period of recovery and return-to-work. The questionnaire included items related to the frequency and  
46  
47 quality of communication with the workplace, the nature of modified duties or accommodations  
48  
49 proposed by the workplace, and perceptions of the outcome of the return-to-work experience. For  
50  
51 employed respondents not currently working with their pre-injury employer, information was collected  
52  
53 on the main reason they were not working with their pre-injury employer. For respondents not currently  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 working, information was collected on whether they had made a return-to-work attempt and their  
4  
5 perception of the main reason they were not currently working.  
6  
7

## 8 *2. Function, recovery and measures of physical and mental health*

9

10  
11 The questionnaire included a range of measures of function, recovery and health outcomes. Current  
12  
13 intensity of pain was measured by the Chronic Pain Grade Scale and pain-related interference with  
14  
15 normal activities was assessed.(22) Measures of self-rated health status and self-rated mental health  
16  
17 status(23-27) were administered along with the SF-12 scale(28) and the Kessler-6 screening tool for  
18  
19 mental disorder symptoms.(29) The questionnaire included a series of items used in the Canadian  
20  
21 Community Health Survey(21) to assess perceptions of work stress, life stress and life satisfaction, sleep  
22  
23 quality, alcohol consumption, and medication use. Questions were also included on current cannabis  
24  
25 use and if use was for therapeutic purposes.  
26  
27  
28

## 29 *3. Interactions between the claimant and the work disability insurance case managers*

30

31  
32 Respondents were asked to assess the quality of interactions with work disability insurance case  
33  
34 managers, both in terms of interpersonal treatment and the quality of the information provided by case  
35  
36 managers.(11, 30)  
37  
38

## 39 *4. Interactions between the claimant and their healthcare providers*

40

41  
42 The questionnaire included items documenting the respondent's main health care provider, whether  
43  
44 difficulty was experienced accessing health care services, whether the use of health care services was  
45  
46 stressful and the respondent's assessment of the clarity of advice provided by health care providers  
47  
48 concerning returning to work.  
49  
50

## 51 *5. Socio-demographic characteristics and pre-injury information on occupation, industry and workplace*

52  
53  
54  
55 size

1  
2  
3 The interview collected information on claimant age, sex, immigrant status, educational attainment,  
4 family structure, union membership, pre-injury occupational tasks and work hours, workplace size and  
5 industry of employment. Respondents also provided information about the amount of personal and  
6 household income in the previous 12 months, and their current main income sources.  
7  
8  
9  
10  
11  
12  
13  
14  
15

### 16 **Interview-administered questionnaire: 36 months**

17  
18 Participants who agreed to be re-contacted will be administered an abbreviated version of the 18 month  
19 questionnaire, retaining topic domains concerning; 1) current labour market status, 2) function,  
20 recovery and measures of physical and mental health and 3) basic socio-demographic characteristics. An  
21 extended questionnaire domain pertaining to cannabis use will be administered to participants  
22 reporting current cannabis use at the 18 month interview. The 36 month interview will be administered  
23 over the period January to December 2021.  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

### 36 **Findings to date**

37  
38 Unweighted descriptive analyses completed to date are summarized in Table 1 and Table 2. The median  
39 age at the time of the baseline interview (approximately 18 months after injury) was 50; participants in  
40 the short duration sample had a median age of 47, whereas those in the long duration sample had a  
41 median age of 51. Over half of the participants (56%) were male. The most common industries were  
42 health care and social assistance (15%), construction, utilities and mining (14%), and transportation and  
43 warehousing (13%), and manufacturing (13%), with significant differences in industry composition  
44 across claim duration groups ( $p=0.003$ ). Approximately 40% of the sample had a household income  
45 greater than \$100,000 without a significant difference in income across claim duration groups.

1  
2  
3 Participants with the longest claim durations had lower education and were less likely to be presently  
4 working. They were also more likely to have suffered a head injury, to currently be receiving services  
5 from the WSIB, to be receiving health care for the treatment of conditions related to the work injury, to  
6 have pain symptoms, and to demonstrate greater health impairment on a range of measures.  
7  
8  
9

10  
11 Results regarding return-to-work with the at-injury employer are displayed in Table 3. Initially, 90% of  
12 participants returned to their at-injury employer. Males, those in the longer claim duration sample,  
13 those in smaller workplaces and those in rural areas were less likely to return to work with their at-  
14 injury-employer. Union members and participants reporting a permanent employment arrangement at  
15 the time of injury were more likely to return to work with their at-injury employer.

17  
18  
19  
20  
21  
22

23  
24 Eighteen months following the work injury incident, 35% of participants reported that they were no  
25 longer working for the at-injury employer (Table 4). Approximately 50% of these workers chose to  
26 terminate employment and 20% reported the employer did not have work available. Approximately 14%  
27 of participants reported that the employer had fired them or terminated the employment relationship  
28 and approximately 10% of participants chose to retire.

### 36 **Strengths and limitations**

37  
38 The Ontario Life After Work Injury Study cohort was designed to address two important limitations in  
39 previous research examining the determinants of adverse health and labour market outcomes following  
40 an episode of work disability—length of follow up, and sample size. In terms of the first, this study  
41 follows a large, representative sample of workers who experienced a disabling work-related injury or  
42 illness for a longer time period than has typically been reported in the current literature. Information  
43 provided by claimants 18 months and 36 months following a disabling work injury will inform  
44 understanding of the long-term consequences to health, function and labour force participation. In  
45 terms of the second, the recruitment of adequate numbers of study participants with the longest

59  
60

1  
2  
3 durations of work disability will provide sufficient statistical power to identify the modifiable and non-  
4 modifiable characteristics of claimants associated with long disability durations, not typically possible in  
5 an inception cohort.  
6  
7  
8  
9

10 This study is not without limitations. Although differences between participants and non-participants on  
11 observed characteristics were minor, there may be important differences in unmeasured characteristics  
12 which may have influenced participation. Further, there will plausibly be differences in labour market  
13 outcomes in the cohort that cannot be accurately accounted for by the self-reported information  
14 obtained by the interviewer-administered questionnaire. Although not available in this context,  
15 longitudinal information on workers' wage and work history from administrative sources would enhance  
16 the interpretation of differences in labour market outcomes.<sup>(31)</sup> We also note that the eligibility criteria  
17 for participation in this cohort was restricted to disability due to a work-related injury or illness. The  
18 many other health conditions that can result in work disability are not represented in this cohort.

22  
23  
24  
25  
26  
27  
28  
29  
30

31 The dual objectives of this cohort, to describe the long-term health and labour market outcomes of  
32 workers disabled by work injury or illness, may have different implications for the external validity of  
33 findings from this cohort. We would be most confident that the long-term health outcomes observed in  
34 this cohort would plausibly generalize to other developed country settings. In contrast, however, the  
35 labour market outcomes observed in this cohort will, to some degree, be a function of the labour and  
36 social security protections specific to this jurisdiction.  
37  
38  
39  
40  
41  
42  
43  
44

45 Although not anticipated by the OLAWIS research team, the experiences of the longitudinal cohort  
46 between the first and the second follow-up interviews will intersect with the COVID-19 public health  
47 emergency. Nationally representative surveys conducted during the emergency found that 28% of  
48 employed Canadians were concerned that they might lose their job or self-employment income as a  
49 consequence of the emergency and 33% of respondents reported that the emergency would have a  
50

56  
57  
58  
59  
60

1  
2  
3 major or moderate impact on their ability to meet financial obligations.(32) To respond to the acute  
4  
5 economic effects of the COVID-19 emergency on households and on employers, the Government of  
6  
7 Canada has rapidly implemented a range of financial relief programs that have the potential to provide  
8  
9 more than \$140 billion in direct support.(33) We anticipate that the economic, social and health impacts  
10  
11 of the unprecedented contraction in the Canadian labour market will have more substantive negative  
12  
13 impacts on workers with health impairments.  
14  
15

16  
17 Over the past two decades, many jurisdictions in the developed economies have achieved important  
18  
19 reductions in the incidence of work-related injury and illness.(1, 34) Paralleling these achievements,  
20  
21 progress has also been made in reducing the burden of disability among workers experiencing a work-  
22  
23 related injury or illness. Research contributions can inform future innovations in workplace practices  
24  
25 and disability insurance provider policies to improve the prevention and management of work disability.
