ABSTRACT

Objectives Affected by COVID-19 pandemic, The Department of Paediatric Dentistry of School and Hospital of Stomatology, Wuhan University was closed in late January 2020, and resumed on 20 April. Our study aimed to explore the effects of COVID-19 pandemic on paediatric dental services which might assist global paediatric dentists to build confidence and make appropriate policies under the pandemic.

Design A retrospective study was performed. Medical records of patients were retrieved but without any private information, including patient name, ID number and address.

Participants All data of the patients from 20 April to 31 July in 2020 and 2019 were extracted and analysed including demographics, dental diagnosis and treatment methods. A total of 18 198 patients were included in the study.

Results During this period, no medical staff or patient was infected with COVID-19 due to dental services. A total of 6485 in 2020 but 11 713 during the same period in 2019 visited the department. Compared with 2019, gender distribution did not change, but age distribution changed with an increase under 6-year-old. The diagnoses including caries, retained primary teeth, malocclusion, deep pits and fissures changed significantly, while pulpitis, apical periodontitis, tooth trauma, early loss of primary teeth, supernumerary teeth showed little change. Aerosol generating procedures were adopted less frequently overall in this period.

Conclusions The reopening of paediatric dental services is proceeding steadily with significant changes in the characteristics of the patients and treatment procedures.

INTRODUCTION

In December 2019, COVID-19 emerged in Wuhan and spread rapidly across the globe, becoming a major public health challenge for countries around the world.¹ The COVID-19 pandemic led to a high case fatality rate up to 2.12% in WHO region-wise till February 2021.²⁻³ A novel highly infectious corona RNA virus (named SARS-CoV-2) was responsible for the COVID-19, which could transmit via droplets or direct contact with infected people or contaminated surfaces.⁴ Due to the transmission

Strengths and limitations of this study

- Based on large sample size, the study explored the influence caused by COVID-19 pandemic on paediatric dentistry.
- Our measures and experience to prevent and control the COVID-19 transmission at the paediatric dental clinic were shared.
- The short-term impact of COVID-19 on paediatric dental care in Wuhan was explored.
- The study only analysed the situation in our hospital, which might not be applicable to some countries or areas.
- Due to the limited time, further research is needed to discuss the medium-term and long-term impact of the COVID-19 on paediatric dental clinic.

routes of COVID-19, many high-contact professions including dentistry were severely affected.⁵ Dental healthcare professionals worked in close proximity to patients. And most dental procedures were aerosol generating procedures (AGPs) which caused a large number of droplets and aerosols, such as use of a high-speed or low-speed handpieces, ultrasonic instruments and water-air syringes.⁶⁻⁹ The standard protective measures were not sufficient to prevent the spread of COVID-19 because of the unique characteristics of dentistry, especially when patients were in the incubation period, or unaware they had been infected.⁷ Therefore, among healthcare personnel, dentists were at an elevated risk of exposure to COVID-19. This risk was even more serious in paediatric dentistry, because affected children frequently presented asymptomatic, mild or moderate clinical manifestations.¹⁰⁻¹² To prevent and control transmission of COVID-19, Wuhan city was locked down on 23 January 2020. On the second day, Hubei province activated level 1 response to public health emergencies. Then all elective treatments to dental patients in Wuhan city were postponed and only emergency dental care was reserved.^{13 14}

The Department of Paediatric Dentistry in WHUSS (School and Hospital of Stomatology, Wuhan University) was the main centre for the routine treatment and care for children's dental diseases in Wuhan. This department provided dental care to around 36 000 children in 2019. From 24 January to 19 April 2020, clinical procedures of this department were completely stopped. During this period, online consultations and oral health instructions were provided, and severe dental emergencies were recommended to the Department of General and Emergency in WHUSS, which was the only available department in WHUSS special for emergency dental services.¹⁴ Although it was important to provide treatment for children who presented with urgent or emergency dental complaints, dental non-emergencies that failed to receive immediate intervention were at an increased risk to exacerbate and even developed urgent or emergent complications. Therefore, the contradiction between the huge paediatric demands and the limited dental service worsened after the closure of the Department of Paediatric Dentistry.^{6 9 13} After being imposed a lockdown for as long as 76 days, Wuhan city successfully contained the spread of the virus. On 8 April 2020, all travel restrictions in and out of Wuhan was removed.¹⁵ On 20 April, the Paediatric Department of WHUSS was reopened and aimed to improve children's dental healthcare.

Similar to Wuhan in China, paediatric dental treatments were completely stopped or significantly influenced in several affected countries.^{6 16–18} Paediatric dentistry was essential children's healthcare. During this evolving and unprecedented COVID-19 pandemic period, it was an important issue to get a balance between prevention of potential exposure to SARS-CoV-2 infection and minimisation of the harm to patients from postponed dental care.^{16 18} New protocols and measures were needed as dental professionals returned to normal practice after weeks or months of confinement in many countries. Some articles have discussed the management of dental practice during the COVID-19 pandemic,^{3 5 6} but few articles explored the situation and changes after the recovery of dental clinics based on large sample data.

In this study, we collected the data of the patients from 20 April to 31 July in 2020 and the corresponding period in 2019 to analyse the impact of the COVID-19 pandemic on the children's dental care. We also shared our experience on restructuring the patient pathway and workflow of healthcare personnel.

MATERIALS AND METHODS

Inclusion and exclusion criteria

The information of the patients who visited the Department of Paediatric Dentistry, WHUSS from 20 April to 31 July in 2020 and the corresponding period in 2019 was retrieved and compared (all private information has not been extracted, including patient name, ID number and address). Any medical record had one or even more information missing was excluded.

Patient and public involvement

Reporting of the study follows the Strengthening the Reporting of Observational Studies in Epidemiology guidelines. Patients or the public were not involved in the design, or conduct, or reporting, or dissemination plans of our research

Workflow of the dental practice personnel

In order to ensure safety after reopening of the hospital, a series of measures had been applied among medical staff which mainly included: nucleic acid testing for all before reopening, personal protection training for employees, adequate provision of personal protective equipment and a complete clinic management system. Please refer to the online supplemental materials for details.

Patient pathway for paediatric dental services

During the pandemic, WHUSS and paediatric dentistry formulated protocols to prevent nosocomial infections of COVID-19. These measures included: online appointment system, medical history collection of COVID-19, body temperature monitoring, provision of nucleic acid reports and so on. Patients needed to make an appointment online in advance, those who lacked an appointment would not be allowed to enter the hospital. The patient triage based on the COVID-19 exposure history was completed on patient arrival. Children and their accompanying persons were required to provide the appointment messages, the children's identity information and the accompanying person's health QR-code. All people needed to receive body temperature assessment. Please refer to the online supplemental materials for details. The questionnaires for COVID-19 are shown in online supplemental appendix tables 1 and 2.

Data collection and management

Data collection included number and demographic information of visited children (age and gender), their diagnosis and treatment options provided by dentists. Data associated with COVID-19 were obtained from the government.¹⁹

All data were classified according to specific standards. Age was divided into four groups: 0–3 years old, 4–6 years old, 7–12 years old, 13 years old and above. For the diagnosis of children, nine common diseases were listed while some uncommon diseases such as traumatic ulcer, central cusp, gingivitis were grouped into other. Treatments were divided into Oral Health Consultation group (they received a comprehensive oral examination and oral health instruction without any dental procedures.) and Oral Health Consultation & Treatment group. The latter group was further divided into AGPs Treatment Group and non-AGPs Treatment Group according to whether any AGPs was used.

Figure drawing and statistical analysis

The data were entered into Excel 2019 (Microsoft corporation, Redmon, Washington, USA) and imported into SPSS V.25.0 (IBM Corporation) for statistical analysis.

Figure 1 The situation of COVID-19 pandemic in Wuhan, Hubei, and daily visits at the Department of Paediatric Dentistry in WHUSS from 20 April to 31 July in 2020 and 2019. The grey shading shows the number of patients with hospitalised COVID-19 in Hubei Province. The red line shows the number of new confirmed COVID-19 cases in Wuhan city. The blue and orange lines represent the number of patients in 2020 and 2019, respectively.

Figures were drawn by Excel. Pearson χ^2 test was used to verify the difference of categorical variables. Significance levels were set as $p < 0.05$ using any test.

RESULTS

The overall recovery process of the Department of Paediatric Dentistry in WHUSS

From 20 April to 31 July, a total of two medical staff experienced fever symptoms. Their test reports on nucleic acid of SARS-CoV-2 were both negative and were diagnosed as influenza instead of COVID-19. As of 31 July, no medical staff or patient had contracted COVID-19 due to medical services.

After reopening on 20 April, a series of measures had been taken to prevent COVID-19 infections and ensure the safety of medical staff and patients. These measures included: changes in the appointment system from a combination of on-site and online to online only; strict verification of identification information before entering the hospital and clinic area; collection of epidemiological information related to COVID-19 of each patient and perfect classified diagnosis and treatment system and so on. All the above measures (Methods and online supplemental materials) ensured the recovery process of the Department of Paediatric Dentistry of WHUSS to be promoted steadily.

The trend of COVID-19 pandemic in Wuhan (23 January to 31 July 2020) is shown in figure 1. The number of daily visits from the reopening day to 31 July 2020 (the blue line) and during the corresponding period in 2019 (the orange line) were retrieved. The daily visits in 2019 were at a comparably stable level, about 80 for average. In 2020, the number of visits remained very low in the early recovery stage (late April), and gradually increased. In the early first half of May, the average

daily visits reached nearly 50, returning to 60% of the same period last year. Since late May, the number of the patients reached a relatively stable level, reaching 60, which was around 60%–80% of the same period in 2019.

Changes in the basic information of the children visiting WHUSS

To further understand the possible changes of the patients' characteristics, basic information of the children who visited the Department of Paediatric Dentistry in WHUSS was obtained. Table 1 shows their gender and age distribution. No significant difference was found in the gender distribution between 2019 and 2020. But a significant difference was seen in the age distribution with an increase of the children under 6 years old (0–3 and 4–6 years old groups) but a decrease of the elder children in 2020.

Changes in the diagnoses of the children visiting WHUSS

The disease diagnoses of the visited children in 2020 are shown in table 2. Since the absolute number of children visiting varied greatly between 2020 and 2019, the percentages of the number of each diagnosis were further compared. Comparison among the 4 months within 2020, the diagnosis (%) of retained primary teeth declined month by month. However, compared with the total patients in 2019, the COVID-19 pandemic has led to a significant increase of the percentage of retained primary teeth. Meanwhile, significant impacts of COVID-19 on the percentage of dental caries, malocclusion, deep pits and fissures were also seen, with an increase in the first diagnosis but decreases in the latter two. The detailed diagnoses for patients in 2019 are shown in online supplemental appendix table 3.

Table 1 Gender and age distribution of the children who visited the Department of Paediatric Dentistry in WHUSS from 20 April and 31 July in 2019 and 2020

	2020 (n=6485) (%)	2019 (n=11 713) (%)
Gender †		
Male	3429 (52.88)	6280 (53.62)
Female	3056 (47.12)	5433 (46.38)
Age ‡*		
0–3 years old	718 (11.07)	593 (5.06)
4–6 years old	2745 (42.33)	4152 (35.45)
7–12 years old	2839 (43.78)	6229 (53.18)
13 years old and above	183 (2.82)	739 (6.31)

The symbol * represents significant difference using Pearson χ^2 test ($P<0.05$).

†There is no significant difference of the gender of the children between 2019 and 2020 using Pearson χ^2 test ($\chi^2=0.918$, $p=0.338>0.05$).

‡The age distribution between 2019 and 2020 was significantly different with an obvious increase of the children under 6 years old (0–3 and 4–6 years old group) and a decrease of the children above 7 years old in 2020 using Pearson χ^2 test ($\chi^2=435.590$, $p<0.001$).

WHUSS, School and Hospital of Stomatology, Wuhan University.

Changes in the treatment operations

In order to analyse the impact of COVID-19 on the implement of dental treatment operations, the data were further collected and shown in table 3. On the whole, a higher proportion of children left the hospital after receiving oral health consultations only in 2020. But from April to July, the proportion of children undergoing treatment operations was increasing while in 2019, the ratio between these two groups was stable. By comparing

Table 3 All visits were grouped into Oral Health Consultation group and Oral Health Consultation & Treatment group according to whether treatment operation(s) was adopted

Time †* ‡ \$*	Total visits	Oral Health Consultation only (%)	Oral Health Consultation & Treatment (%)	P value
April 2020	159	81 (50.94)	78 (49.06)	$p<0.001^*$
April 2019	1129	332 (30.92)	797 (69.08)	
May 2020	1879	581 (34.46)	1298 (65.54)	$p=0.006^*$
May 2019	3205	876 (27.48)	2329 (72.52)	
June 2020	1805	622 (29.41)	1183 (70.59)	$p<0.001^*$
June 2019	3111	898 (27.33)	2213 (72.67)

AGP, aerosol generating procedure.

dropped and non-AGPs treatment increased in 2020. Among April to July in 2020, the proportion of AGPs treatment showed an obvious increase month by month, but still at a lower level than the corresponding month of 2019. In April 2020, only 10 cases were operated with AGPs. Gradually, such attempts had been expanded, reaching nearly 30% in May, which increased month by month, finally reaching a level similar to 2019 in July.

Paediatric dental clinic provides all oral healthcare for children and adolescents which includes extensive procedures. Some representative treatment methods were selected and percentages of these treatment methods were calculated. The average number of teeth treated during a single visit was also displayed in online supplemental figure 1.

DISCUSSIONS

After Wuhan city experienced the COVID-19 pandemic attack in 2020, the medical industry including dental care service had been seriously affected. To explore the changes of paediatric dental services during the pandemic, the information of children who visited the Department of Paediatric Dentistry of WHUSS including gender, age, diagnoses and treatment options they received was extracted. By comparing with the same period in 2019, we found that the COVID-19 pandemic had an impact on the policies of dental hospitals and clinics, the distribution of children's age and oral diseases, as well as the treatment operations to the patients.

The strategy of pathway for patients and the performance of patient triage were reorganised and adopted till now. However, it still had some limitations. The

collection of COVID-19 exposure history as well as the checking for body temperature were completed only on patient arrival.^{20 21} But if the patient or the accompany person was a potential COVID-19 infected person or had been contacted with an infected person, the spread of COVID-19 was hard to be avoided on the way to the hospital. Judson *et al* proposed self-triage and self-scheduling based on the phone, which was being rapidly adopted on health systems around the world.²² So this kind of system for patient triage, both on the phone and on patient arrival, which had the potential to greatly improve triage efficiency and prevent unnecessary visits during the COVID-19 pandemic, was a valuable measure for risk assessment of COVID-19 for patients.^{22 23}

The regular dental healthcare in Wuhan was influenced by COVID-19 pandemic, including paediatric patients and dentists. The COVID-19 pandemic had affected children's dental healthcare in Wuhan, and the short-term changes in children caused by COVID-19 pandemic were mainly due to community closure and delayed treatment. A significant increase was observed in the children at younger ages (0–6 years old), which might be attributed to the closure of the community. During this period, children were required to stay at home all day, feeling upset by losing outdoor activities, and daily dental care was sometimes ignored.²⁴ Coupled with poor self-control and poor oral cleaning, young children were more prone to dental diseases. At the same time, due to the closure, children were unable to visit the hospital to receive regular oral examination and the fluoride anti-caries treatment, which made the incidence of dental caries further increased.²⁵

At present, the impact of delayed treatment on children mainly lead to the change of the reasons for these children's visit, which was mainly reflected in the change of disease distribution in our study. A significant decrease for dental trauma was found in 2020 (April to June), which may be attributed to reduced outdoor activities. Although community closure was cancelled at the end of March, educational institutions especially kindergartens and elementary schools did not return to work at that time. To avoid the possibility of infection, most children were required to go out less frequently by their caregivers.²⁶ In Wuhan, China, summer vacation usually started from early July. It was found that for 2019, the percentage of dental trauma in July also reduced greatly either.

Hopcraft and Farmer investigated the impact of COVID-19 on dental services in Australia from February 2020 to September, finding that the pandemic had a significant impact on the provision of dental services to children from lower socioeconomic backgrounds, and the delayed dental care was likely to contribute to poorer oral health and long-term problems for many Australians.²⁷ Different from this study, we found that the impact of the COVID-19 pandemic on Wuhan mainly concentrated in the first 3 months after reopening. In the fourth month (July 2020), the characteristics of children gradually returned to normal. It was speculated that the restriction measures in Wuhan lasted only 3 months.

If the restrict time was prolonged, the impact might be more serious. Therefore, our study found that the impact of COVID-19 pandemic and the deferral of dental treatment in Wuhan mainly focused on the short-term impact, while the medium-term and long-term impact might be limited, needing more research to explore.

Another obvious change occurred in the dentists' treatment concepts, breaking the original routines.⁵⁻⁷ Especially in late April when the outpatient service just recovered, more than half of the children did not receive any operation in the initial appointment. In addition, some parents or caregivers were also worried about the risk of COVID-19 infection by AGPs, so they refused to receive any treatment for their children but dental health consultation. With the resumption process proceeding in an orderly manner, the concerns of both dentists and parents decreased, so more dentists and parents were willing to receive AGPs till the end of July.

Many current guidelines recommend minimising the use of AGPs,^{7 9 28 29} but non-AGPs operations cannot solve some common dental diseases, such as endodontic treatments for pulpitis. Taking into account the complexity of children's oral diseases and their limited ability of oral hygiene control, failing to intervene in time will worsen the diseases and eventually make more complicated treatments necessary. Nevertheless, since the global pandemic has not yet been eliminated, the possibility of a recurrence of COVID-19 in Wuhan cannot be ruled out. Some medical staff hold the view that preventive measures must also be paid attention to such as fluoride anti-caries treatment.³⁰ The application of fluoride can effectively prevent dental caries, which will reduce the probability of these children suffering from dental caries in the future and reduce their visits to the hospital.

As a retrospective report, we extracted and classified the data of the 4 months since the reopening of dental healthcare work in the Paediatric Dentistry of WHUSS. In-depth comparisons were conducted from three aspects, namely: comparison within 2019, comparison within 2020 and comparison between 2019 and 2020. In 2019, the data were mostly stable, and the dentists' treatment choice was directly determined by the patient's disease diagnosis, with no extra factors to worry about. The only fluctuation came from the summer vacation in July as discussed above. However, in 2020, a large amount of changes happened. When dentists just returned to work on April, most of them tried to avoid AGPs operations while parents also refused to take their children to hospital when it was not urgent enough regarding the danger of hospital environment. In this exploratory period, the attitudes of dentists and patients were relatively conservative. At the end of May, Wuhan city carried out nucleic acid tests on all citizens, which gave both dentists and patients incentives. The numbers of dentists at work, visited patients, patients treated and patients receiving AGPs also increased. This phenomenon was more significant from May to June. When entering July, after the first 3 months of exploration, the concepts of both dentists and patients have

become stable. This month-to-month change has begun to shrink, approaching the degree compared with the same month in 2019. The overall reopening process has achieved phased success.

CONCLUSION

The COVID-19 pandemic has indeed brought an impact on children's dental care. Under this attack, lower visit number as well as younger age distribution can be found. And AGPs operations were used less frequently. Our department resumed medical service at the end of April, without any example to follow. Through the efforts of various departments of the hospital, plans and medical procedures have been formulated. Looking back at our reopening process, it cannot be perfect enough, but it is still satisfactory. Our experience may help global paediatric dental healthcare workers build confidence and make appropriate policies for resuming high-quality dental services during COVID-19 pandemic.

Competing interests None declared.

Patient consent for publication Not applicable.

Ethics approval This study involves human participants and was approved by the Ethics Committee of School and Hospital of Stomatology, Wuhan University with the reference ID No. 2020-B70. Consent for participation in the study was not obtained because this retrospective study did not interfere with patients, nor did it involve any patient privacy. And due to the large sample size, not all patients could be found so consent for participation was not obtained. This study does not involve animal subjects.

Provenance and peer review Not commissioned; externally peer reviewed.

Data availability statement Data are available upon reasonable request. Data including detailed medical record without any private information is available upon reasonable request.
