ABSTRACT

Introduction In the pandemic, healthcare professionals face even higher levels of stress. It is therefore a priority to estimate the impact of the pandemic on mental health and to propose targeted strategies to improve resilience. The aims of the study were to (1) assess the mental health of healthcare professionals working with patients with COVID-19 and identify social determinants that may increase the risk of negative outcomes; and (2) test the effectiveness of an intervention to improve the resilience of healthcare professionals in France.

Methods and analysis To evaluate the first objective, a national longitudinal study will be carried out among healthcare professionals working with patients with COVID-19. Participants will be recruited via an internet link that will be widely disseminated on social media, mailing lists, medical boards and French medical journals. Primary outcomes are mental health distress/symptoms and resilience. Secondary outcomes are burnout, social and occupational supports and substance use. To meet the second objective, an interventional study will be conducted. The main outcome is the effectiveness of the PsySTART-Responder and the Anticipate.Plan.Deter program. Qualitative analyses will be conducted to understand the strategies used to cope with the pandemic.

Ethics and dissemination The study protocol was approved by the *Sorbonne Université* Ethical Committee (No 2020-CER-2020-27) and was declared to French Commission on Information Technology and Liberties, CNIL (N°2222413, 20-05-2021). The results of this study will provide a better understanding of mental health and social inequalities in mental health among healthcare professionals working in the pandemic; data about the effectiveness of the PsySTART-Responder and the Anticipate.Plan.Deter interventional program in France.

INTRODUCTION

Healthcare workers are in the frontline of the COVID-19 pandemic. The epidemic occurs in a scenario of pre-existing financial constraints and tensions between health professionals and French policy makers.¹ The

Strengths and limitations of this study

- This online longitudinal study will provide knowledge about the dynamic of mental health and social inequalities in mental health among healthcare workers during the COVID-19 pandemic in France.
- The study will assess the effectiveness of the PsySTART-Responder self-report questionnaire and the Anticipate.Plan.Deter interventional program in France.
- This project proposes a methodology that could be easily translated to other disaster contexts and populations.
- The sample will be large and diverse (partnerships with many professional associations) but not random.
- No baseline data from before the COVID-19 pandemic are available to allow comparisons.

deterioration of working conditions and its impact on patient care is one of the reasons for the unprecedented strikes that have been ongoing throughout France since 2019.^{1 2} In this context of crisis in the health sector, professionals have a higher risk of mental health difficulties such as depression,³⁻⁵ psychological distress and, in more severe cases, post-traumatic stress disorder (PTSD).⁶ During the SARS-CoV-1 epidemic, a study conducted in Taiwan⁷ indicated a high prevalence of depression (38.5%), insomnia (37%) and PTSD (29.7%) among healthcare workers. In the beginning of the COVID-19 pandemic, the estimated prevalence of anxiety was 22.0%, and depression was 19.2% among 214 healthcare workers in Wuhan.⁸ However, a recent meta-analysis about the psychosocial impact of COVID-19 among healthcare workers demonstrated 31.8% prevalence of depression, 11.4%

PTSD, 27.8 insomnia, 46.1% psychological distress and 37.4% burnout.⁹ The number of epidemiological studies about physical and mental health significantly increased since the emergence of the COVID-19 pandemic,¹⁰ and a myriad of studies associate occupational factors with negative mental health outcomes among healthcare professionals.

Professionals involved in the diagnosis, treatment and care of patients infected by the SARS-CoV-2 coronavirus are confronted with increased sources of stress factors. For instance, they may fear for their own life or the life of beloved ones with risks of personal and family contamination (criterion A of the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) on post-trauma)¹¹; may be exposed to an unusual number of deaths among patients, colleagues or relatives (criterion A of the DSM-5 on post-trauma)⁹; may have to deal with degraded working conditions¹² such as exacerbated workload, lack of personal protective equipment and lack of organisation; may have to deal with complex moral and ethical issues¹³ if having to perform expectant triage; may suffer discrimination and stigmatisation for working with patients with COVID-19¹⁴; and may be exposed to an overabundance of information (*infodemic*) that might lead to confusion and mistrust.¹⁵ Therefore, the management of patients with COVID-19 was described as a risk factor for increased anxiety and depression.^{16–19}

In addition to the exposed factors, some studies have also suggested the influence of social determinants on negative outcomes. During the SARS-CoV-1 health crisis, a Taiwanese study indicated that psychiatric symptoms were more common among healthcare workers who were young and had little social or family support.⁷ Recent studies show that physicians, nurses, caretakers and other health professionals involved in the management of COVID-19 present higher prevalence of anxiety.^{9 20 21} Among nurses, physiotherapists and caretakers, it could be explained by the fact that, besides long-hour shifts, they are in closer contact with patients which can lead to compassion fatigue.²⁰ Another study about physicians working with patients with COVID-19 indicated that social support was significantly associated with a good quality of sleep and negatively associated with anxiety and stress.²²

Regarding media exposure, healthcare workers have not rarely been considered as heroes. If at one hand it adds recognition and improves self-esteem, on the other hand it exacerbates social pressure and, for some, the feeling of illegitimacy. A heroic image goes with the illusion of absence of failure, of illness and the idea that they have to be ready to help at any time.²³ Nevertheless, in contrast to this heroic status, some healthcare workers have been discriminated and stigmatised due to fear of SARS-CoV-2 exposure.²⁴

Healthcare workers often demonstrate difficulties or resistance seeking for help and taking care of themselves. This reluctance is well documented among doctors^{25 26} and could be partially explained by concerns about confidentiality²⁷ or by the inadequacy of self-care education.²⁸

The French government has been proposing psychosocial support to healthcare professionals since the beginning of the COVID-19 pandemic, mostly by hotlines (24/7)²⁹ and psychosocial education. To our knowledge, no targeted strategy specific to this population has been offered.

Bearing this in mind, a pilot study was carried out by the French Institute of Health and Medical Research between 18 May and 25 June 2020 to (1) assess the prevalence and factors associated to mental health symptoms in frontline healthcare workers and (2) test the feasibility of the PsySTART-Responder (PsySTART-R) questionnaire and the Anticipate.Plan.Deter (APD) programme to enhance individual capacity to cope with stress factors. PsySTART-R is a self-report questionnaire designed to quickly assess the presence of risk factors to psychological distress.^{30 31} The APD programme, a stepped care programme, is proposed when individuals are found to have moderate to high levels of stress factors on the PsySTART-R questionnaire with the aim of helping participants create their own resilience plan to cope with stress factors.³⁰

Participants were recruited in three different public hospitals in the Paris Region. Forty-two professionals responded to the survey with a satisfactory completion rate (missing data varied between 2% and 7%) and a median questionnaire completion time of 18 min. The small proportion of missing data and participants' commitment to the APD programme indicated a good feasibility rate. The small sample size did not allow the significance of the association to be demonstrated; however, preliminary analysis of the responses suggests some results. Almost 60% of the participants presented signs of depression (measured by Patient Health Questionnaire (PHQ-8)) and these symptoms appeared to be more frequent in participants who had been more heavily exposed to stress risk factors according to PsySTART-R (73.3%) than in those who had been less exposed (51.8%) ($p=0.3026$). The PTSD score (measured by PTSD Checklist (PCL-5)) was higher among those who reported none or little team support (24.7) than others (10.9) ($p=0.098$). In contrast, PTSD score was not higher among those who reported little or no support from their hierarchy (10.6) if compared with the others (12.6) ($p=0.419$). The results of the pilot study showed good feasibility rates for PsySTART-R and the APD programme in France.

The results from this pilot study raised a need for a more comprehensive study to assess, at a national level, the (1) determinants, particularly social components, that would impact mental health; and (2) to test the effectiveness of PsySTART-R and the APD programme among healthcare professionals rather than those only working in a hospital context. Thus, we propose to conduct a longitudinal epidemiological survey based on the following hypotheses:

1. Healthcare professionals with high levels of exposure to the COVID-19 pandemic (patient care challenges, crisis standards of care, direct life threat, family impact,

low professional support) may develop mental health symptoms or disorders.

2. There could have been social inequalities in mental health among healthcare professionals due to their distinct social and economic status.
3. Participation in PsySTART-R and the APD programme would lead to reduced symptoms of depression, anxiety and post-traumatic stress, and improved levels of resilience capacity.
4. Mental health disorders might develop in the long term (in particular, anxiety and depression), and a re-exposition to COVID-19 surges could deteriorate or worsen the mental health of healthcare workers.

With regard to the previous hypotheses, the PsyCOVER project (Longitudinal survey on the Psychological Impact of the COVID-19 Pandemic in Healthcare Workers) aims to:

1. Assess symptoms of depression, anxiety and post-traumatic stress, as well as resilience capacity among healthcare professionals working with patients with COVID-19 1 year (13–15 months) and 2 years (25–27 months) after the first COVID-19 surge in France (March 2020).
2. Identify social determinants that might influence the mental health of healthcare professionals in the COVID-19 context.
3. Assess the effectiveness of PsySTART-R and the APD program in the pandemic context in France.
4. Assess the resilience strategies used by healthcare workers (APD program) to face the COVID-19 pandemic.

METHODS

Population study

We propose to conduct a longitudinal epidemiological survey among healthcare professionals who have been working with patients affected by the COVID-19 in France.

We considered healthcare workers as defined by the French Public Health Code: (1) medical professionals: physicians, midwives, dentists; (2) pharmacists and medical physicists: pharmacists, pharmacy dispensers, hospital pharmacy dispensers, medical physicists; (3) auxiliary paramedics: nurses, nursing assistants, childcare assistant, ambulance driver, physiotherapist, occupational therapist, psychomotrician, medical electroradiology manipulators.

Health-related professions and administrative staff working in health facilities will also be included in the study: (4) embalmer, counsellor, psychologist, social worker; and (5) medical secretary, hospital manager (finance, human resources, information system, logistics, technical, etc), executive or administrative agent (secretary, admissions, archivist, accountant, etc), executive or logistic agent (storekeeper, cook, maintenance staff, etc), manager or technical agent (hospital services agent, stretcher bearer, plumber, heating engineer, electrician, etc).

Participants must be over 18 years, speak one of the study languages (English and French) and give their informed consent. Students or trainees will be eligible to the study.

Recruitment

The study will be divided into two waves. The first wave will be conducted 13 months from the beginning of the first surge in France (April 2021), and the second wave, 1 year after the first wave of the PsyCOVER project (April 2022). The first wave of the PsyCOVER project has been carried out, by coincidence, in the third and fourth surges of the COVID-19 pandemic in France.

Design study

First wave

Participants will be recruited via three ways: (1) by an internet link disseminated in social media (Facebook, Twitter and LinkedIn), (2) by an email invitation sent to more than 200 medical and scientific boards (identified *a priori*) in order to have them disseminate the link of the survey to affiliates/members, and (3) by contacting institutional and academic partners via email, asking for their participation and help in disseminating the internet link.

To participate in the study, healthcare workers will click on the survey link to access the questionnaire and will be asked to answer questions related to inclusion criteria. If inclusion criteria are granted, participants will access the Information Note and will be asked to register by entering their most frequently used email address (either personal or occupational). An email will be automatically sent via the LimeSurvey platform to each participant with a personal link to the questionnaire. As a result of the anonymisation option from the LimeSurvey platform, the email address entered by participants during the registration process will be stored in the 'participant database' and will be separated from the 'questionnaire database'. It will therefore not be possible to link participants' email address to responses.

To access the questionnaire, participants will click on the received personal link. This first page relates to the participants' consent, which will be collected in electronic format on the secure LimeSurvey platform.

Second wave

All registered participants will be reinvited to participate to the second wave of the study. As in the first wave, participants will receive an email sent directly by the LimeSurvey platform through the 'participant database' in the second wave (April 2022).

Data collection

The survey will be divided into three parts: the epidemiological part (part 1), the interventional part (part 2) and the evaluation of the interventional part (part 3) (figure 1).

The first wave of the survey (April to June 2021) consists of an epidemiological part to investigate the mental health of healthcare workers (part 1) and an interventional part

Figure 1 Overview of the Psychological Impact of the COVID-19 Pandemic in Healthcare Workers (PsyCOVER) project. W1 P1, wave 1 part 1; W1 P2, wave 1 part 2; W2 P1, wave 2 part 1; W2 P3, wave 2 part 3.

to assess the efficacy of the PsySTART-R self-report questionnaire and the APD program (part 2).

Parts 1 and 2 will last 6 weeks in total. In week 1, participants were asked to fulfil parts 1 and 2. In weeks 2, 3 and 4, the questionnaire will be proposed once a week. In week 6, information about mental health will be collected again (part 3) to evaluate the efficacy of the intervention (part 2).

The second wave of the survey consists of reconducting the epidemiological survey 1 year after the first wave of the survey.

Patient and public involvement

Patients or the public were not involved in the design, or conduct, or reporting, or dissemination plans of our research.

Description of the interventional part (part 2)

The ultimate goal of the intervention in the PsyCOVER project is to increase the participants' ability to cope with stress in this pandemic. First, with the help of the PsySTART-R self-report questionnaire, participants will identify stressors. Second, whenever necessary, they will be proposed to build a personal resilience plan using the APD program.

PsySTART-R COVID-19³² is an adapted version of the PsySTART-R questionnaire³⁰ that prompts users to indicate which of the 18 risk factors of stress they have experienced during a given period (eg, 24 hours). PsySTART-R does not measure symptoms of acute distress; rather, it measures exposure to the event itself (in this case COVID-19-related stressors) including the nature of the event (eg, severe patients), the standard of care (eg, lack of personal protective equipment) and the impact on participants and their families (eg, exposure to virus, life-threatening feeling, unable to return home, concerns about the safety or well-being of relatives).

If participants are exposed to at least one high stress factor or two moderate stress factors, they will be invited to use the self-administered APD program.³³ APD consists of three different phases:

1. Anticipate: brief introduction to the nature of possible traumatic and cumulative stressors among workers and their impact. Example: the traumatic stress response can include exposure to a life-threatening

event, personal or family contamination, witnessing an unusually high number of deaths.

2. Plan: understanding the possible effects of stress on oneself and developing a 'personal resilience plan', which involves identifying and documenting expected stress reactions and response challenges (ie, stressors in specific scenarios, as COVID-19), as well as positive factors such as social support and positive strategies used to face the event and find sense in life. Example: to list expected stress reactions. These can be thoughts, feelings, behaviours and physical symptoms (how do you deal with negative emotions, what do you know about your limits).
3. Determine: implementation of a personal plan developed in the 'Plan' phase. An essential component of this program is learning to monitor one's own exposure to stress so that the user/participant knows when to initiate the personal resilience plan. Example: to monitor reactions to stress and activate the adaptation plan whenever needed.

PsySTART-R and the APD program do not require the presence of trained investigators, something particularly relevant in the context of the COVID-19 pandemic when social distancing is highly recommended.

Measures

Primary outcomes

For the present study, primary outcomes for waves 1 and 2 will be (table 1):

- Depression, assessed by the PHQ-9,³⁴ a 9-item self-report questionnaire.
- Generalised anxiety disorder, assessed by the Generalized Anxiety Disorder Scale,³⁵ a 7-item self-report questionnaire.
- PTSD, assessed by the PCL-5,³⁶ a 20-item self-report questionnaire that assesses the 20 DSM-5 symptoms of PTSD.
- Resilience capacity, assessed by the Connor-Davidson Resilience Scale 10,³⁷ a 10-item self-report questionnaire.
- Exposure to stress factors, assessed by the PsySTART-R questionnaire, as described above.

Secondary outcomes

Burnout is a risk factor of negative mental health outcomes and it has been demonstrated to be prevalent among healthcare workers.³⁸ Hence, we propose to investigate its prevalence among healthcare professionals working with patients with COVID-19 in France.

The Maslach Burnout Inventory³⁹ is the most commonly used instrument to measure burnout. It captures three dimensions of burnout: emotional exhaustion, depersonalisation and personal accomplishment. For each of the 22 items, the respondent is required to describe his feelings on a 7-point scale.

Social and occupational supports are often mediators of traumatic events and influence the onset of mental health distress/disorders.⁴⁰ These will be investigated separately.

Table 1 Overview of measures that will be collected in the PsyCOVer project, first and second waves, 2021–2022

	Inclusion/first wave (part 1) (Week 1)	Interventional study (first wave, part 2) (Week 1 to week 4)	Follow-up intervention study (first wave, part 3) (Week 6)	Second wave

APD, Anticipate.Plan.Deter; CD-RISC-10, Connor-Davidson Resilience Scale; GAD-7, Generalized Anxiety Disorder Scale; MBI, Maslach Burnout Inventory; PCL-5, PTSD Checklist; PHQ-9, Patient Health Questionnaire; PsyCOVer, Psychological Impact of the COVID-19 Pandemic in Healthcare Workers; PsySTART-R, PsySTART-Responder; PTSD, post-traumatic stress disorder.

Occupational and social supports will be assessed using an adapted version of Ruiller's questionnaire.⁴¹

The consumption of psychoactive substances can be both a cause and a consequence of mental health disorders. We propose to assess it by using an adapted version from the IMPACTS (French acronym for Investigation of post-attacks traumatic events and therapeutic management and support of people involved in the January 2015 terrorist attacks in the Paris Region) Epidemiological Survey.⁴² Tobacco and alcohol consumptions will also be investigated using an adapted version from the same survey.

Other measures

To identify factors which are potentially associated with mental health outcomes and to test our hypotheses, we will collect (table 1):

- Sociodemographic characteristics (sex, month and year of birth, level of education, marital status, number of children, income level, country of graduation).
- Work-related questions (profession—specialisation/training, professional specialty, time in current position at the time of the crisis, year of board inscription/beginning of clinical practice, change of professional position/role during the crisis, geographic location of exercise—city, type of exercise—individual private practice, multidisciplinary medical centre, public hospital, private hospital).
- Essential questions about health and mental health status (adapted from IMPACTS Epidemiological Survey).⁴²
- Perceived discrimination (adapted from IMPACTS Epidemiological Survey).⁴²

- Exposure to difficult life events (prior to the COVID-19 pandemic) (adapted from IMPACTS Epidemiological Survey).⁴²

Qualitative measure

Participants (who have identified one high stress factor and two moderate factors in PsySTART-R) will be invited to respond to the APD program (table 1). Among the questions, participants will be asked to write down perceived expected stress reactions, perceived response challenges related to stress, a social support plan, as well as positive coping strategies and possible resilience factors. Participants' compliance with PsySTART-R and the APD will be collected.

Sample size and power calculation

Considering the expected prevalence of the principal outcomes at 14% for depression, 16% for anxiety and 20.91% for PTSD,⁴³ with a statistic power of 80% and a value of 5% for the type I risk, the number of subjects required to have sufficient statistical power is between 415 (for depression), 312 (for anxiety) and 179 (for PTSD). As there is likely that there is 20% attrition between the two waves of the PsyCOVer survey, we estimated that 519 subjects would be needed in wave 1 to study depression, 390 to study anxiety and 223 to study PTSD. Therefore, 519 subjects will be needed to recruit in the first wave of PsyCOVer project and 415 in the second wave.

ANALYSIS

In order to answer objectives 1 and 2 (wave 1, part 1), we will conduct descriptive analyses to determine the prevalence of mental health symptoms (primary outcomes) among participants. To test our hypotheses (1 and 2), we will analyse the distribution of these primary outcomes according to participants' sociodemographic characteristics, general work conditions, exposure to stress factors, general health and mental health status, substance use and social support. We will then assess if the primary results indicate that mental health symptoms are more frequent in a specific group and also the presence of social inequalities. In addition to the analyses to address the first objective, we will analyse the distribution of the secondary outcomes (burnout, social and occupational supports and substance use) and identify associated factors to these outcomes. Finally, we will describe the evolution of the outcomes' prevalence between waves 1 and 2. To meet the third objective (wave 1, part 2, and 3), we will (1) investigate the relation between the exposures to stress factors measured by PsySTART-R with the primary and secondary outcomes, and (2) compare the evolution of the resilience capacity and mental health symptoms between week 1 and week 6 among participants who used the intervention program compared with those who have not used it.

In the second wave of the survey, a sensitivity analysis will be performed to compare sociodemographic data

and mental health status in the first wave for subjects who participated in both waves with those who participate in the first wave of the study but do not participate in the second wave. Finally, to answer the fourth objective, we will perform qualitative analyses on data from the APD program.

For the qualitative analysis, we will consider all the information provided by the participants who engaged in the APD program. First of all, we will list all different responses—expected stress reactions, expected coping strategies (positive and negative) and social support strategies—placing a number next to the response. If multiple participants report the same response, a unique number referring to each of the participants will be listed next to that response. As a result, we will have a list for each APD question and how many participants have mentioned each of the different responses. If two or more respondents refer to the same strategy/plan/action but using different wording, a review team will select and record the wording that they feel is most accurate and most likely to be understood by a member of the target population (healthcare workers). The transcribed data will be coded and analysed using the software program Atlas.ti.⁴⁴

Statistical analysis

Descriptive analyses regarding the distribution of mental health outcomes will be presented as mean/SD for normally distributed variables, and median/IQR for not normally distributed variables, for continuous data and as proportion for quantitative data. For continuous data, differences between means/medians between groups will be assessed using a t-test for normally distributed or Mann-Whitney-Wilcoxon test for non-normally distributed parameters. Categorical data and differences of proportion between groups will be assessed using a χ^2 test or Fisher's test (if $n < 5$).

After descriptive analyses, we will identify factors associated to the primary outcomes with regression models and structural equation modelling. Finally, regarding the objective 1 (waves 1 and 2), we will describe the evolution of outcome prevalence in two times: (1) the global trend of change (increasing or decreasing) in prevalence at first and second waves—we will test the significance with McNemar test, and (2) the total change between first and second waves by calculating the proportion of participants who changed from one group to another.⁴⁵ The proportion of change's significance will be tested by calculating the 95% CI (± 1.96 times the SE).

Analysis will be carried out in R version 4.1.0.⁴⁶

Ethics

The study protocol was approved by the Sorbonne Université Ethical Committee (No 2020-CER-2020-27) and was reported to the French Commission on Information Technology and Liberties, CNIL (N°2222413, 20-05-2021). All methods will be performed in accordance with the relevant guidelines and regulations. Participants may contact the research team to discuss the findings of the study

which will be in the form of aggregated results as data will be anonymous and non-identifiable to the researcher.

The diffusion of study results will be implemented rapidly so that healthcare workers could benefit from it, especially if a new surge of the COVID-19 pandemic occurs. Thus, we will be able to provide the scientific community with knowledge about a population that is not often surveyed with regard to mental health. Besides, we will also be able to present information about the efficacy of a program to monitor levels of exposure to stress factors and to propose the use of a personal resilience plan to mitigate stress.

Study status

Recruitment started on April 19, 2022 and ended on October 19, 2022. Data collection for the first wave began on April 19, 2022 and ended on January 12, 2022.
