

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

Abstract

Objective: To examine SARS-CoV-2 vaccine confidence, attitudes and intentions in Australian adults.

Methods: Nationwide survey in February-March 2021 of adults representative across sex, age and location. Vaccine uptake and a range of putative drivers of uptake, including vaccine confidence, socioeconomic status, and sources of trust, were examined using logistic and Bayesian regressions for vaccines generally and for SARS-CoV-2 vaccines.

Results: Overall 1,166 surveys were collected from participants aged 18-90 years (mean 52, SD of 19). Seventy-eight percent reported being likely to receive a vaccine against COVID-19. Higher SARS-CoV-2 vaccine intentions were associated with: increasing age (OR: 1.04 95%CI [1.03-1.044]), being male (OR: 1.37, 95% CI [1.08 – 1.72]), residing in the least disadvantaged area quintile (OR: 2.27 95%CI [1.53 – 3.37]) and a self-perceived high risk of getting COVID-19 (OR: 1.52 95% CI [1.08 – 2.14]). However, 72% of participants did not believe that they were at a high risk of getting COVID-19. Findings regarding vaccines in general were similar except there were no sex differences. For both the SARS-CoV-2 vaccine and vaccines in general, there were no differences in intentions to vaccinate as a function of education level, perceived income level, and rurality. Knowing that the vaccine is safe and effective, and that getting vaccinated will protect others, trusting the company that made it and getting vaccination recommended by a doctor were reported to influence a large proportion of the study cohort to uptake the SARS-CoV-2 vaccine. Seventy-eight percent reported the intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post-vaccine.

Conclusions: Seventy-eight percent of Australians are likely to receive a SARS-CoV-2 vaccine. Key influencing factors identified in this study (e.g. knowing that the vaccine is safe and effective, getting a doctor's recommendation to get vaccinated) can be used to inform public health messaging to enhance vaccination rates.

Keywords: COVID-19, Infection control, Public Health, Preventive Medicine, Respiratory infections

Strengths and limitations of this study

- This research captured a large, representative sample of the adult Australian population across age, sex, location, and socioeconomic status.
- We have self-reported Australian uptake intentions and attitudes on general vaccines and COVID-19 vaccine, and intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post SARS-CoV-2 vaccine.
- We examine a range of drivers and factors that may influence intent to get the SARS-CoV-2 vaccine uptake, including vaccine confidence, demographics and socioeconomic status.
- The survey is based on established behavioural theories, and is the Australian arm of the international iCARE survey which to date has collected global comparative information from over 90,000 respondents in 140 countries.
- Our survey was only available in English, which may have led to an underrepresentation of ethnic groups, and participation was voluntary, so our sample may be prone to selection bias from those with more interest or engagement in COVID-19.

Introduction

The SARS-CoV-2 (COVID-19) pandemic has resulted in an estimated 211 million cases and 4.43 million deaths worldwide, including 44,028 cases and 981 deaths in Australia (1), as of August 2021.

The R0 value has increased from 2-3 for the original Wuhan SARS-CoV-2 virus to 5-6 for the Delta variant of the SARS-CoV-2 virus currently dominating the world (2). Whilst vaccinated individuals can be infected with and transmit SARS-CoV-2, the vaccines reduce the likelihood for serious illness and subsequent hospitalisation and death by greater than 80% and 85% (3). Therefore, vaccinated populations are pivoting from the prevention of SARS-CoV-2 infections to instead accepting that the virus is endemic with the aim to minimise serious illness, hospitalisation, and death (4, 5)

Minimising serious illness, hospitalisations, and deaths will require high vaccination rates for SARS-CoV-2, and ongoing preventative health behaviours such as physical distancing and wearing face masks (6) to protect the unvaccinated (e.g. young children) and those in which the vaccine is less effective such as the immunocompromised.(7) It is now clear that combined behavioural strategies and vaccination (including boosters), are the pathway out of perpetual strict population level restrictions, which in Australia have included limiting gatherings, restricting education and work attendance, stay at home orders and closing both state and international borders (8, 9). Although these restrictions have been effective at reducing COVID-19 transmission and have prevented large numbers of deaths to date (10, 11), they come with serious economic, social and mental health costs that are unacceptable in the long term (8).

Australia is a country with a strong public health record, backed by high vaccination rates, high socioeconomic status, low population density and a universal free health care system. (12) These factors, alongside the strict policies including lockdowns, and Australia being an island nation, making it easier to secure borders, had contributed to Australia largely controlling the pandemic

1
2
3 prior to the emergence of the Delta variant.(12) However, having a low SARS-CoV-2 vaccination rate,
4 due to public concerns over the safety of the Astra Zeneca vaccine and a lack of supply of the mRNA
5 vaccines, Australia has been susceptible to recent delta variant outbreaks.
6
7
8
9

10
11 Vaccine uptake is critical to the long-term management of the COVID-19 pandemic. To date, over
12 11% of the world's population have received at least one dose of a SARS-CoV-2 vaccine (3). Vaccine
13 supply and uptake needs to be accelerated globally to enhance protection against COVID-19.(13)
14
15 Vaccine hesitancy and vaccine confidence are key determinants of vaccine uptake, and it is vital to
16 understand factors associated with hesitancy. Vaccine confidence refers to the trust in the vaccines,
17 the providers who administer it, and the science, processes, and policies behind it (14). Vaccine
18 hesitancy is the sense of uncertainty in vaccines for a particular belief or reason.(14, 15) Vaccine
19 hesitancy and reduced confidence may result in the refusal of, or delay in the acceptance of, a
20 vaccination (16). Both vaccine hesitancy and confidence are complex and can be influenced by many
21 determinants, (16) broadly grouped into three categories: 1) Contextual socio-politico-cultural
22 factors, e.g., compatibility of vaccination with religious beliefs; 2) Individual and group influences,
23 e.g., personal perception of the vaccine, or influences from the social and peer environment; and 3)
24 Vaccine specific factors, e.g., issues directly related to the vaccine or vaccination such as the
25 accelerated development of vaccines for SARS-CoV-2 may increase safety concerns in the population
26 (8). Existing work on population intentions around the SARS-CoV-2 vaccines is emerging globally. A
27 French study conducted early in the pandemic (March 2020) found that 26% of participants would
28 not accept to receive a SARS-CoV-2 vaccine if it became available. (17) This was more prevalent
29 amongst those in lower-income categories, young women and those older than 75 years of age. In
30 the UK, 14% of participants in a study were unwilling to receive a vaccine, with 23% being unsure. (6)
31
32 Similar to the French study, females and those from lower-income groups, reported being less likely
33 to have a SARS-CoV-2 vaccine if available. (6)

1
2
3 The vaccine confidence index (VCI) consist of four questions to understand a person's perceptions
4 about if vaccines are safe, important, effective, and/or compatible with religious beliefs. (18). The
5 VCI was developed following the identification of key drivers which influence the public's confidence
6 in vaccines. (14) Data has suggested approximately 1-in-5 Australians were hesitant regarding SARS-
7 CoV-2 vaccines in the early stages of the COVID-19 pandemic in March/April 2020: with 14% to 24%
8 respondents being unsure or unwilling to get a vaccine if available (19, 20).

17

18 This study identifies characteristics of Australians who intend or did not intend to get the vaccine in
19 March 2021. Australia offers a unique case study to gain insights and inform mitigation strategies
20 which could be applied globally. As attitudes towards the SARS-CoV-2 vaccine may vary over time,
21 this new information will be able to inform current public health campaigns and policy (20, 21) and
22 assist with effectively targeting those who currently have lower vaccine intentions. Hence here we
23 aim to characterise the beliefs, intentions, and hesitancy of Australians towards vaccines
24 generally (importance, safety and efficacy), and to SARS- CoV-2 specifically, to inform strategies to
25 address this and increase uptake.

Methods

This project is part of the Australian arm of the International COVID-19 Awareness and Responses Evaluation (iCARE) study, which is investigating people's understanding, attitudes, beliefs, and actions towards the COVID-19 pandemic. (22) The Montreal Behavioural Medicine Centre, the lead institution, (23) has REB approval from the Comité d'éthique de la recherche du CIUSSS-NIM (Centre intégré universitaire de santé et de services sociaux du Nord-de-l'île-de-Montréal), approval#: 2020-2099/25-03-2020. This paper reports the analysis of the new vaccination questions asked in the third round of the Australian longitudinal survey (24); which comprised a national representative sample. The third round included new questions on attitudes towards the COVID-19 vaccination and intention to vaccinate against COVID-19 in Australia, therefore longitudinal comparison with earlier rounds (24) is not possible. Here we report the nationally representative cross-sectional analysis of respondents in this third survey conducted in early 2021. This project was approved by the Monash University Human Research Ethics Committee (#ID: 24449).

Sampling

Survey respondents were recruited by an online sampling provider that sent out invitations between February 14th and March 7th, 2021. By this time, Australia had recorded 28,947 COVID-19 cases with variable virus impacts and policy approaches across states and a lack of national coordination. At a state level, Western Australia was lifting a lockdown (February 5th, 2021) and Victoria had entered a "circuit breaker," 5-day lockdown having had more than 100 days in lockdown in 2020 (February 12th, 2020). The first public COVID-19 vaccinations were available on the 21st of February, 2021. Electronic survey invitations were emailed to approximately 12,000 adults having a residential address in Australia, and briefly described the survey content, estimated survey duration, and a link to the online survey. The first page of the survey described the study, its purpose, and advised readers that continuing to the next page would be an indicator of consent to participate in the study. All participants who completed the online survey were reimbursed by ISO 26362 as per industry

1
2
3 requirements. Representative sampling for key demographics of the Australian population was done
4
5 using quota sampling for age, sex, and residential location (state/territory and remoteness area).
6

7 **Patient and public involvement**

8
9
10 As part of the main iCARE study, there are several community collaborators who provide continual
11
12 input into the development of the survey design, ensuring that the items are relevant and
13
14 appropriately worded. For Australia, the survey was reviewed by the Monash Partners Consumer
15
16 and Carer group and involved two members paid for their time to identify text that wasn't clear or
17
18 irrelevant to Australia, and recommend alternative wording and areas to clarify. Other community
19
20 members and contacts of the researchers provided input into the timing to complete the survey, and
21
22 subsequently this feedback resulted in the survey being shortened to reduce participant burden.
23
24

25 **Analysis Plan**

26
27 Participant demographic data included residential postcode, which were mapped to the Australian
28
29 Bureau of Statistics remoteness areas and socioeconomic index for areas (SEIFA). (25) Specifically,
30
31 the index of relative socioeconomic disadvantage (IRSD) was applied and divided into five quintiles,
32
33 from 1 (most disadvantaged) to 5 (most advantaged). Ethnicity information provided by participants
34
35 was used to make two groupings of "Australian/New Zealand/UK" and everyone else.
36
37 Descriptive statistics reported the participant demographics and attitudes for a series of vaccine-
38
39 related questions including the VCI. (14, 18).
40
41
42

43 To characterise the beliefs, intentions and hesitancy of Australians towards vaccines generally and
44
45 SARS- CoV -2 vaccines specifically, a series of univariate logistic regressions were done with
46
47 dichotomous outcomes. Responses were dichotomised using the most extreme positive response
48
49 e.g. "Always" vs other. To examine robustness, regressions were repeated by re-dichotomising
50
51 outcomes to include the two most extreme responses instead of one. Unlike in similar analyses (18),
52
53 our outcomes could not be examined using ordinal logistic regression because of low numbers in
54
55 some response categories.
56
57
58
59
60

1
2
3 Possible predictors examined in the logistic regressions, included age, sex, essential worker status,
4 belief that a participant is at high risk, residential area, flu vaccination status, education level,
5 ethnicity, perceived income level, and IRSD quintile. Ethnicity data was missing for n=431
6 participants, therefore, these results were exploratory only. Responses to the VCI questions were
7 also examined. All results are displayed as odds ratios, with 95% confidence intervals.
8
9

10 Sensitivity analyses involved Bayesian logistic regression to enabled global comparisons with a
11 recent Lancet publication. (18) and were conducted on the same outcome variables as in the logistic
12 regressions. Normal priors (0,1) were set for each regression parameter and used 5,000 burn-in
13 steps and 50,000 sampling iterations. Statistical analyses used STATA SE/v16. Significance level was
14 set as <0.05.
15
16

17 Results

18 There were 1166 survey respondents reported in this cross-sectional analysis. Response rate was
19 approximately 10% for new participants and 60% for those in the longitudinal arm (24). Ages ranged
20 from 18-90 years with a mean of 51.7 years (table 1), similar to the Australian population, apart from
21 an overly represented group of participants aged 70 years or more. Sampling ensured a reasonable
22 representativeness across sex, rurality and the three largest states (New South Wales, Victoria and
23 Queensland). Education levels were similar to the Australian population. Less than half of
24 participants (45%) were in full-or part-time work, lower than national statistics reported for the
25 same time period (63%), and likely due to the overly represented 70+ age group. Fifteen percent
26 reported being essential workers, with 7% healthcare workers. There was minimal missing data
27 (table 1), except for ethnicity, with 50% respondents identifying as Australian/UK/NZ (n=580), 13%
28 as other (n= 155) but 37% were missing (n=431).
29

44
45
46
47
48
49
50
51

52 Sixty-five percent of participants generally accept routine vaccines for themselves or for their
53 children, with 6% either rarely or never accepting vaccinations (table 2). At the time of this study,
54 only 27 (2%) participants had already received at least one dose of a COVID-19 vaccination. The
55
56
57
58
59
60

1
2
3 majority (78%) reported that they were likely to get the SARS-CoV-2 vaccine (table 2), and fifteen
4
5 percent of all participants were either unlikely or very unlikely to get the SARS-CoV-2 vaccine.
6
7 Seventy-two percent of our study cohort did not believe that there were at a high risk of being
8
9 infected with COVID-19.
10

11
12
13
14 The VCI questions showed most Australians (>60%) strongly agreed on the safety, importance, and
15
16 effectiveness of general vaccines (figure 1). Fifty-seven percent strongly agreed that general vaccines
17
18 are compatible with their religious beliefs (figure 1). Approximately ten percent of participants did
19
20 not know whether vaccines are safe or effective. (figure 1)
21
22

23 24 25 **Predictors for vaccine uptake**

26
27 Determinants that were similar for both general (Table 3) and SARS-CoV-2 vaccine uptake intention
28
29 (Table 4) included:
30

31
32 Higher likelihood of vaccine uptake was significantly associated with:
33

- 34 • Increasing age with Odds Ratio (OR) = 1.6 (95% Confidence Interval: 1.4-1.8) and 2.0 (95% CI:
35
36 1.8-2.3) for general and SARS-CoV-2 vaccine respectively; residing in the least disadvantaged
37
38 areas SES quintile (OR = 2.1 (95% CI: 1.4-3.2) and 2.7 (95% CI: 1.5-3.4) for general and SARS-
39
40 CoV-2 vaccines).
- 41 • Identifying as Australian/NZ/UK with an OR = 2.3 (95% CI: 1.6 - 3.3) and 1.9 (95% CI: 1.3 –
42
43 2.7) for general and SARS-CoV-2 vaccines; however, as noted there was much missing data
44
45 for the ethnicity variable, therefore this result is considered exploratory only.
- 46 • Strong agreement with the VCI questions. For example, strong agreement with the
47
48 statement “Vaccines are effective” had an OR = 14.6 (95% CI: 10.9 – 19.5) for general
49
50 vaccine and 14.0 (95% CI: 10.4 – 18.9) for SARS-CoV-2 vaccine.
51
52
53
54
55

56
57 Lower likelihood of vaccine uptake was significantly associated with:
58
59
60

- Being a healthcare worker: With an OR of 0.5 (95%CI: 0.3 – 0.8) and 0.5 (95%CI: 0.3 – 0.8), for general and SARS-CoV-2 vaccines, respectively. However, this is exploratory only due to the small sample of healthcare workers and inability to delineate what worker type (e.g. allied health, medical, social worker, etc.)

There were no significant findings for educational level, perceived income or residential rurality.

Differences between the general vaccines and the new COVID vaccines:

- There were no differences between the sexes for the likelihood of general vaccine uptake, whilst SARS-CoV-2 vaccine intention to uptake was significantly higher for men compared to women with OR of 1.37(95% CI: 1.08 – 1.72).

Factors that might influence decisions to get the SARS-CoV-2 vaccine:

Having information that the SARS-CoV-2 vaccine is safe (85%), effective (85%), will help protect people around the participant (80%), and trusting the company who developed the vaccine (78%) were reported to influence the participants somewhat or to a great extent to get vaccinated (Table 5). A doctor's recommendation (72%) and convenience factors (72%) were also positive predictor variables for vaccine uptake. Other positive predictors include believing that the participant was at high risk of getting COVID-19 or suffering from severe complications (69%), increasing civil liberties (68%), and seeing others get vaccinated (66%).

Sensitivity analyses:

Bayesian regression analyses produced very similar results to initial logistic regression analyses. The regressions repeated with re-dichotomising outcomes to include the two most extreme responses instead of one, showed similar findings (supplementary table).

Discussion

1
2
3 We examined the beliefs, intentions, and hesitancy of 1166 Australians towards vaccines in general
4 and to the SARS-CoV-2 vaccine in a large, nationally representative cross-sectional analysis of a
5 surveys in early 2021. Seventy-eight percent of all participants reported being likely to get the SARS-
6 CoV-2 vaccine when it became available to them. Rates of both general vaccine uptake and SARS-
7 CoV-2 vaccine uptake increased with age, believing that vaccines are safe and effective, and residing
8 in the least disadvantaged socioeconomic region. Being male was associated with higher intentions
9 to get the SARS-CoV-2 vaccine but had no statistically significant difference to general vaccine
10 intention compared to females. There were no statistically significant differences in education level,
11 perceived income level or rurality and rates of either general or SARS-CoV-2 vaccine acceptance.
12 Strong influencing factors reported to convince people to uptake the SARS-CoV-2 vaccine were;
13 knowing that the SARS-CoV-2 vaccine is safe and effective; trusting the vaccine producers; knowing
14 it will help protect people close to them; recommendations from doctors to get vaccinated; and
15 convenience getting the vaccine.
16
17

19
20
21
22
23
24
25
26
27
28
29
30
31
32
33

34 The following factors were identified as having more of an influence on vaccination rates, and hence
35 could be inform public health policies and messaging to enhance vaccination rates. Having
36 knowledge that the SARS-CoV-2 vaccine is safe and effective will encourage a large proportion of the
37 study cohort to get vaccinated. These two factors are encompassed in the VCI and were recently
38 examined in a large international study. (18) Together, they are likely to play the largest role in the
39 uptake of the SARS-CoV-2 vaccine. Responsible, accurate reporting of the balance of risks and
40 benefits in the media and social media is likely important to build trust in the vaccines and the
41 companies that manufacture them.(26) Since trust in the vaccine companies is identified as a strong
42 influencing factor in encouraging vaccination, this needs to be reaffirmed by focusing on the
43 stringent regulatory processes the companies must adhere to, which can be conveyed in consistent
44 and transparent public health messaging. Participants also indicated that knowing that the SARS-
45 CoV-2 vaccine would protect those around them, was a significant factor influencing intention to
46

1
2
3 vaccinate. Whilst those who are vaccinated can still transmit SARS-CoV2, transmission is decreased
4
5 meaning family and friends are more protected, (27) which appeals to pro-social or altruistic
6
7 attitudes, known to effectively increase vaccination rates.(28) Another key driver of vaccine uptake
8
9 likelihood in our study was getting a recommendation from a doctor, aligned with previous
10
11 immunisation programs, including in the H1N1 pandemic, and should be encouraged with the SARS-
12
13 CoV-2 vaccine. (21) Medical professionals will benefit from consistent updated access to accurate
14
15 information on the SARS-CoV-2 vaccine, countering non evidence based anti-vaccination messages,
16
17 outlining benefits and risks, interpreting evidence as it emerges and personalising it to the
18
19 individuals who seek care. (21, 29)
20
21
22
23
24

25 Convenience factors such as time needed or travel requirements to get vaccinated have also been
26
27 identified as a strong influencing factor. This could translate to greater numbers of local vaccination
28
29 sites in Australia, alongside the rollout of mass vaccination hubs, and of vaccinations to GP clinics,
30
31 pharmacies, schools, and workplaces, already shown to increase the rate of other vaccinations
32
33 including the annual influenza vaccine. (30) Here 68% of participants noted intention to get
34
35 vaccinated if it offered them increased civil liberties, such as going to concerts or sporting events.
36
37
38
39
40

41 When choosing to get vaccinated, the perceived likelihood of infection, the prevalence and severity
42
43 of the relevant disease are key in the decision making process. (31) In early 2021 in our study, 72% of
44
45 all participants did not believe that they were at a high risk of getting COVID-19, likely reflecting the
46
47 low numbers of infections, hospitalisations and deaths in Australia at that time. (32) Misinformation
48
49 in the media also equated COVID-19 severity to that of the seasonal flu (33). These factors are likely
50
51 to have presented obstacles to initial vaccination uptake in Australia, with participants perceived a
52
53 higher risk of getting COVID-19 reporting 50% higher likelihood of getting vaccinated. Previous
54
55 research on the SARS-CoV-2 vaccine, as well as vaccination research during the 2009 H1N1 pandemic
56
57 echo our results. (29, 34). Leveraging anticipated regret, shown to be one of the strongest predictors
58
59
60

1
2
3 for vaccine intention, could also be further explored to enhance SARS-CoV-2 vaccination rates. (29,
4
5 35) Consistent with other early surveys (36), we noted that men report the most willingness to
6
7 receive a SARS-CoV-2 vaccine, however, this intention may not translate to gender differences in
8
9 vaccination uptake (37).

10
11
12
13
14 Exploratory findings based on a small sample, suggested that healthcare workers and those not
15
16 identifying themselves being from Australia/NZ/UK were less likely to accept both general and the
17
18 SARS-CoV-2 vaccines. Considering the influence that healthcare workers have on the general
19
20 population, their high exposure rates this presents a barrier to both effective vaccine uptake and to
21
22 infection rates control. A 2021 review found an average of 23% (range: 4% to 72%) of healthcare
23
24 workers reported vaccine hesitancy. The review also found that being male, older and a doctor were
25
26 associated with higher rates of SARS-CoV-2 vaccine acceptance in healthcare workers. (38) The
27
28 current study did not delineate between types of healthcare workers (e.g. doctors, nurses, allied
29
30 health). Given pending policies around mandatory healthcare worker vaccination, the knowledge,
31
32 attitudes and beliefs driving this behaviour needs further exploration. Additionally, our findings
33
34 identified a higher rate of vaccine hesitancy in people who did not identify their ethnicity as
35
36 Australian/New Zealanders or UK groups, consistent with past research in this and other vaccines.
37
38 (29) However, the findings for both these high-risk groups need to be interpreted with caution due
39
40 to the small sample size. Better data here could aid in further targeting policy-based
41
42 communications and interventions.
43
44
45
46
47
48
49

50
51 Public health authorities need to provide transparent, easy to interpret information on the SARS-
52
53 CoV-2 vaccines to the general population, as highlighted by Eastwood et al during the H1N1
54
55 pandemic. (39) This will aid in alleviating the confusion which may stem from misinformation
56
57 present in the media and online networks. Furthermore, we echo the suggestions made in Seale et
58
59 al., which includes tailoring messages and engaging community leaders in disseminating information
60

1
2
3 about vaccines in culturally and linguistically diverse groups, with the known influence of social
4 groups and community leaders of similar backgrounds. (40) For healthcare workers, engagement
5 and education is important, given the important role they play in modelling health-promoting
6 and education is important, given the important role they play in modelling health-promoting
7 behaviour for the general public (37). Mandatory influenza vaccination is already in place for many
8 healthcare workers in Australia, and mandatory SARS-CoV2 vaccination has been introduced for
9 aged care workers and some jurisdictional healthcare workers with likelihood of scale up. (38).
10 Finally, healthcare workers beliefs and attitudes to the SARS-CoV2 vaccine may reflect similar
11 concerns to their broader community as seen in the UK with hesitancy being more frequent in non-
12 white British healthcare workers, female sex, and younger age (41).

The strengths of our study include a large, generally representative sample across Australia and evidence based approaches including the vaccine confidence index. Limitations to our study include that this the survey was only available in English, which is likely to have reduced representation of ethnic groups. Internet access was required, which may account for the increased representation of those in the least disadvantaged quintile. Furthermore, since we rely on self-reported behaviour, there is the risk of a social desirability bias, with participants potentially over-reporting socially desirable traits in their responses and the voluntary nature of the survey makes it prone to a selection bias. (9, 42)

There is a paucity of studies on what influences people to consider taking the vaccine in Australia in 2021, where access to the SARS-CoV-2 vaccines is increasing, but still limited by age and occupation at the time of the survey. Since this survey, the rapid emergence of the highly transmissibility Delta variant, the major challenges of large scale, extended lockdowns escalating the imperative for rapid vaccination, and highlighting the importance of work in this field. Behavioural research such as the iCARE study can inform policymakers in understanding the public's knowledge, attitudes,

1
2
3 perceptions and beliefs towards the SARS-CoV-2 vaccine, which in turn drive their behaviours
4
5 including vaccination and can aid with targeting public health messages. (21)
6
7
8
9

10 **Conclusion:**
11
12
13

14 Given the worldwide morbidity, hospitalisation, and death from COVID-19, the established safety
15 and effectiveness of widely tested vaccines to prevent these complications, and the imperative to
16 accelerate vaccination globally including in Australia, the results of this study on vaccine hesitancy
17 are important. Here we show that vaccine safety, effectiveness, trust in the companies, and
18 recommendations from doctors are important determinants of vaccine intentions. Further work to
19 understand vaccine hesitancy in identified target groups including culturally and linguistically diverse
20 groups and healthcare workers are important moving forward to support equity in vaccine uptake.
21 This work can directly inform strategies to optimise communication and SARS-CoV-2 vaccine uptake,
22 especially in Australia, now vital as the Delta variant takes a grip on the country.

Contributorship statement

SB and KL led study conceptualisation. JE and JG were responsible for the statistical analyses. JG and JE wrote the first draft of the paper. JB and HT are the senior authors and guarantors. All authors contributed to the development of the research question, study design in relation to the Australian data analysis, interpretation of the results, critical revision of the manuscript for important intellectual content, and approved the final version of the manuscript. JB attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Competing interests

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Funding

This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors

Data sharing statement

Data can be made available to approved researchers by contacting the corresponding author.

Ethics Approval Statement

The studies involving human participants were reviewed and approved by Monash University Human Research Ethics Committee (MUHREC Project ID: 24449). The patients/participants provided their written informed consent to participate in this study.

Where applicable, variable categories have been collapsed to allow for concordance with national data published by the Australian Bureau of Statistics (ABS):

- 1: Australian population breakdowns by age, sex, and state of residence are obtained from the Australian Bureau of Statistics (ABS). Age is presented in 10-year bands, and the first band that is comparable to the current study is 20-29 years. The proportion of Australians by age is calculated as the proportion of those 20 or over.
- 2: <https://www.abs.gov.au/statistics/people/population/regional-population/2019-20>
- 3: The Australian survey data present a combined the graduate/postgraduate or university degree category, and a combined TAFE and high school category: <https://www.abs.gov.au/statistics/people/education/education-and-work-australia/latest-release#data-download>
- 4: National estimates for ethnicity were obtained by assessing the “country of birth” data provided by the ABS 2016 Census. Whereas the survey ‘ethnicity’ variable was created using survey responses to the ethnicity item.

Table 2: Uptake intentions and attitudes on general vaccines and COVID-19 vaccine, and intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post COVID-19 vaccine.

	N (%)
Had already received at least 1 dose of COVID-19 vaccine	27 (2)
Likelihood of getting COVID-19 vaccine if it were available today	
Extremely likely	597 (53)

Table 4: Factors reported by n=1,081 Australians that may influence intent to get the SARS-CoV-2 vaccine. *Combined 'somewhat' and 'to a great extent' responses. Influencing factors are ranked in descending order, from most likely to influence SARS-CoV-2 vaccine uptake to least likely.

N (row %)	Combined strongest likelihood *	To a great extent	Somewhat	Very Little	Not at all	I don't know	Total
Having information that the vaccine is safe and unlikely to have any major long- term side effects	921 (85)	661 (61)	260 (24)	78 (7)	50 (5)	32 (3)	1,081
Having information that the vaccine is effective (i.e., provides a high degree of protection)	913 (85)	661 (61)	252 (23)	78 (7)	58 (5)	31 (3)	1,080
Knowing that getting vaccinated will help protect others around me	858 (80)	548 (51)	310 (29)	107 (10)	72 (7)	36 (3)	1,073
Trusting the company who developed the vaccine (Pfizer, Moderna, Sinopharm, etc.)	839 (78)	474 (44)	365 (34)	112 (10)	75 (7)	50 (5)	1,076
Receiving the vaccine dose(s) according to the manufacturers' instructions	818 (76)	505 (47)	313 (29)	122 (11)	90 (8)	42 (4)	1,072
Wanting to contribute to high population rates of vaccination to achieve 'herd immunity'	791 (74)	476 (44)	315 (29)	131 (12)	101 (9)	52 (5)	1,075
The convenience of getting the vaccine (e.g., requires little time, no need to travel far)	772 (72)	417 (39)	355 (33)	143 (13)	118 (11)	42 (4)	1,075
Getting a recommendation from my doctor to get vaccinated	774 (72)	438 (41)	336 (31)	163 (15)	97 (9)	37 (3)	1,071
Believing that I am high risk of getting COVID-19 or suffering severe complications	729 (69)	361 (34)	368 (35)	175 (17)	119 (11)	37 (3)	1,060
Learning that being vaccinated would allow me to attend public events (e.g., concerts, sporting events) or travel	734 (68)	422 (39)	312 (29)	179 (17)	121 (11)	39 (4)	1,073
Seeing more and more people getting the vaccine	708 (66)	335 (31)	373 (35)	191 (18)	135 (13)	34 (3)	1,068
Hearing that other people have positive attitudes towards the vaccine	687 (64)	306 (29)	381 (36)	195 (18)	151 (14)	35 (3)	1,068
Only needing one dose of the vaccine to be protected	647 (61)	302 (28)	345 (32)	203 (19)	159 (15)	56 (5)	1,065
Believing that getting vaccinated would reduce my worries and anxiety	635 (60)	273 (26)	362 (34)	225 (21)	156 (15)	43 (4)	1,059
Getting a recommendation from my employer to get vaccinated	386 (52)	158 (21)	228 (31)	163 (22)	147 (20)	44 (6)	740

Vaccine Confidence Index

Supplementary 1: Vaccine uptake sensitivity analysis: Univariate regression analyses with possible predictors that influence general vaccine uptake (left columns) and SARS-CoV-2 vaccine uptake (right columns), using “Always/Mostly” and “Extremely/Somewhat likely” answer options. *Age variable is scaled to have a mean of 0 and unit standard deviation. **Ethnicity data was missing for n=431, therefore results for this variable are exploratory only.

	Do you generally accept vaccines for yourself or for your children?				If a vaccine for COVID-19 were available today, what is the likelihood that you would get vaccinated?				
	Outcome: “Always/Mostly” vs not				Outcome: Extremely/somewhat likely v. not				
	OR	95% confidence interval	P		OR	95% confidence interval	p

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1,2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-6
Objectives	3	State specific objectives, including any prespecified hypotheses	6
Methods			
Study design	4	Present key elements of study design early in the paper	7
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	7
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	7
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	8
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	8-9
Bias	9	Describe any efforts to address potential sources of bias	8
Study size	10	Explain how the study size was arrived at	7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	9
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	8
		(b) Describe any methods used to examine subgroups and interactions	8
		(c) Explain how missing data were addressed	10
		(d) If applicable, describe analytical methods taking account of sampling strategy	N/A
		(e) Describe any sensitivity analyses	9
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	9
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	N/A
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	9
		(b) Indicate number of participants with missing data for each variable of interest	10
Outcome data	15*	Report numbers of outcome events or summary measures	10-11
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Table 3

		(b) Report category boundaries when continuous variables were categorized	Table 1
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	11
Discussion			
Key results	18	Summarise key results with reference to study objectives	12
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	15
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	12-15
Generalisability	21	Discuss the generalisability (external validity) of the study results	15
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	N/A

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Abstract

Objective: To examine SARS-CoV-2 vaccine confidence, attitudes and intentions in Australian adults as part of the iCARE Study.

Design and setting: Cross-sectional online survey conducted when free COVID-19 vaccinations first became available in Australia in February, 2021.

Participants: Total of 1,166 Australians from general population aged 18-90 years (mean 52, SD of 19)

Main outcome measures: Primary outcome: Responses to question “If a vaccine for COVID-19 were available today, what is the likelihood that you would get vaccinated?”

Secondary outcome: Analyses of putative drivers of uptake, including vaccine confidence, socioeconomic status, and sources of trust, derived from multiple survey questions.

Results: Seventy-eight percent reported being likely to receive a SARS-CoV-2 vaccine. Higher SARS-CoV-2 vaccine intentions were associated with: increasing age (OR: 1.04 95%CI [1.03-1.044]), being male (1.37 [1.08–1.72]), residing in least disadvantaged area quintile (2.27 [1.53–3.37]) and a self-perceived high risk of getting COVID-19 (1.52 [1.08–2.14]). However, 72% did not believe they were at a high risk of getting COVID-19. Findings regarding vaccines in general were similar except there were no sex differences. For both the SARS-CoV-2 vaccine and vaccines in general, there were no differences in intentions to vaccinate as a function of education level, perceived income level, and rurality. Knowing that the vaccine is safe and effective, and that getting vaccinated will protect others, trusting the company that made it and vaccination recommended by a doctor were reported to influence a large proportion of the study cohort to uptake the SARS-CoV-2 vaccine. Seventy-eight percent reported the intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post-vaccine.

Conclusions: Most Australians are likely to receive a SARS-CoV-2 vaccine. Key influencing factors identified (e.g. knowing vaccine is safe and effective, and doctor’s recommendation to get vaccinated) can inform public health messaging to enhance vaccination rates.

Keywords: COVID-19, Infection control, Public Health, Preventive Medicine, Respiratory infections

Strengths and limitations of this study

- This research captured a large, representative sample of the adult Australian population across age, sex, location, and socioeconomic status around the time that free COVID-19 vaccinations first became available to Australians in February, 2021.
- We have self-reported Australian uptake intentions and attitudes on general vaccines and COVID-19 vaccine, and intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post SARS-CoV-2 vaccine.
- We examine a range of drivers and factors that may influence intent to get the SARS-CoV-2 vaccine uptake, including vaccine confidence, demographics and socioeconomic status.
- The survey is based on established behavioural theories, and is the Australian arm of the international iCARE survey which to date has collected global comparative information from over 105,000 respondents in 140 countries.
- Our survey was only available in English, which may have led to an underrepresentation of ethnic groups, and participation was voluntary, so our sample may be prone to selection bias from those with more interest or engagement in COVID-19.

Introduction

The SARS-CoV-2 (COVID-19) pandemic has resulted in an estimated 211 million cases and 4.43 million deaths worldwide, including 44,028 cases and 981 deaths in Australia (1), as of August 2021.

The R0 value, which represents the average number of people a single infected person can expect to transmit a virus to in a completely susceptible population, has increased from 2-3 for the original Wuhan SARS-CoV-2 virus to 5-6 for the Delta variant of the SARS-CoV-2 virus currently dominating the world (2). Whilst vaccinated individuals can be infected with and transmit SARS-CoV-2, the vaccines reduce the likelihood for serious illness and subsequent hospitalisation and death by greater than 80% and 85% (3). Therefore, vaccinated populations are likely to pivot from the prevention of SARS-CoV-2 infections to instead accepting that the virus is endemic with the aim to minimise serious illness, hospitalisation, and death (4, 5).

Minimising serious illness, hospitalisations, and deaths requires high vaccination rates for SARS-CoV-2, and ongoing preventative health behaviours such as physical distancing and wearing face masks (6) to protect the unvaccinated (e.g. young children) and those in which the vaccine is less effective such as the immunocompromised (7). It is now clear that combined behavioural strategies and vaccination (including boosters), are the pathway out of perpetual strict population level restrictions, which in Australia have included limiting gatherings, restricting education and work attendance, stay at home orders and closing both state and international borders (8, 9). Although these restrictions have been effective at reducing COVID-19 transmission and have prevented large numbers of deaths to date (10, 11), they come with serious economic, social and mental health costs that are unacceptable in the long term (8).

Australia is a country with a strong public health record, backed by high socioeconomic status, low population density and a universal free health care system (12). There is also high vaccine uptake in

1
2
3 general. For example, rates of Hepatitis B immunisation amongst 1-year olds in Australia was 95% in
4
5 2020, which was higher when compared to other high-income countries such as the United States
6
7 (91%) and Canada (84%).(13) These factors, alongside the strict policies including lockdowns, and
8
9 Australia being an island nation, making it easier to secure borders, had contributed to Australia
10
11 largely controlling the pandemic prior to the emergence of the Delta variant (12). However, having a
12
13 low SARS-CoV-2 vaccination rate, due to public concerns over the safety of the Astra Zeneca vaccine
14
15 and a lack of supply of the mRNA vaccines, Australia has been particularly susceptible to recent delta
16
17 variant outbreaks (14).
18
19
20
21
22

23 Vaccine uptake is critical to the long-term management of the COVID-19 pandemic. To date, over
24
25 11% of the world's population have received at least one dose of a SARS-CoV-2 vaccine (3). Vaccine
26
27 supply and uptake needs to be accelerated globally to enhance protection against COVID-19 (15).
28
29 Vaccine hesitancy and vaccine confidence are key determinants of vaccine uptake, and it is vital to
30
31 understand factors associated with hesitancy. Vaccine confidence refers to the trust in the vaccines,
32
33 the providers who administer it, and the science, processes, and policies behind it (16). Vaccine
34
35 hesitancy is the sense of uncertainty in vaccines for a particular belief or reason (16, 17). Vaccine
36
37 hesitancy and reduced confidence may result in the refusal of, or delay in the acceptance of, a
38
39 vaccination (18). Both vaccine hesitancy and confidence are complex and can be influenced by many
40
41 determinants, as identified by the Strategic Advisory Group of Experts on Immunization (SAGE)
42
43 working group on vaccine hesitancy, (18) and are broadly grouped into three categories: 1)
44
45 Contextual socio-politico-cultural factors, 2) Individual and group influences, and 3) Vaccine specific
46
47 factors, see Box 1 for examples (8). Existing work on population intentions around the SARS-CoV-2
48
49 vaccines is emerging globally (19). A French study conducted early in the pandemic (March 2020)
50
51 found that 26% of participants would not accept to receive a SARS-CoV-2 vaccine if it became
52
53 available (20). This was more prevalent amongst those in lower-income categories, young women
54
55 and those older than 75 years of age. In the UK, 14% of participants in a study were unwilling to
56
57
58
59
60

1
2
3 receive a vaccine, with 23% being unsure (6). Similar to the French study, females and those from
4
5 lower-income groups, reported being less likely to have a SARS-CoV-2 vaccine if available (6).
6
7
8
9

10 The vaccine confidence index (VCI) consist of four questions to understand a person's perceptions
11 about if vaccines are safe, important, effective, and/or compatible with religious beliefs (21). The VCI
12 was developed following the identification of key drivers which influence the public's confidence in
13 vaccines (16). Data has suggested approximately 1-in-5 Australians were hesitant regarding SARS-
14
15 CoV-2 vaccines in the early stages of the COVID-19 pandemic in March/April 2020: with 14% to 24%
16
17 respondents being unsure or unwilling to get a vaccine if available (22, 23).
18
19
20
21
22
23
24
25

26 This study identifies characteristics of Australians who intend or did not intend to get the vaccine in
27 March 2021. Australia, as an island nation that overall had minimal to no community transmission of
28 SARS CoV-2 prior to the delta outbreak, offers a unique case study to gain insights and inform
29 mitigation strategies which could be applied globally. As attitudes towards the SARS-CoV-2 vaccine
30 may vary over time, this new information will be able to inform current public health campaigns and
31 policy (23, 24) and assist with effectively targeting those who currently have lower vaccine
32 intentions. Hence here we aim to characterise the beliefs, intentions, and hesitancy of Australians
33 towards vaccines generally (importance, safety and efficacy), and to SARS- CoV-2 specifically, to
34 inform strategies to address this and increase uptake.

Methods

This project is part of the Australian arm of the International COVID-19 Awareness and Responses Evaluation (iCARE) study, which is investigating people's understanding, attitudes, beliefs, and actions towards the COVID-19 pandemic (25). The Montreal Behavioural Medicine Centre, the lead institution, (26) has research ethics board approval from the Comité d'éthique de la recherche du CIUSSS-NIM (Centre intégré universitaire de santé et de services sociaux du Nord-de-l'île-de-Montréal), approval#: 2020-2099/25-03-2020. The iCARE aims, measures and survey construction are reported in detail elsewhere (25) and the survey results and publications resulting from this international collaboration are available at <https://mbmc-cmcm.ca/covid19/>. This paper reports the analysis of the new vaccination questions asked in the third round of the Australian longitudinal survey (27); which comprised a national representative sample (survey included in supplementary documents). The third round included new questions on attitudes towards the COVID-19 vaccination and intention to vaccinate against COVID-19 in Australia, therefore longitudinal comparison with earlier rounds (27) is not possible. Here we report the nationally representative cross-sectional analysis of respondents in this third survey conducted in early 2021. This sub-project was approved by the Monash University Human Research Ethics Committee (#ID: 24449).

Sampling

Survey respondents were recruited by an online sampling provider that sent out invitations between February 14th and March 7th, 2021. By this time, Australia had recorded 28,947 COVID-19 cases with variable virus impacts and policy approaches across states and a lack of national coordination. At a state level, Western Australia was lifting a lockdown (February 5th, 2021) and Victoria had entered a "circuit breaker," 5-day lockdown having had more than 100 days in lockdown in 2020 (February 12th, 2020). The first public COVID-19 vaccinations were available on the February 21st, 2021. Electronic survey invitations were emailed to approximately 12,000 adults having a residential address in Australia, and briefly described the survey content, estimated survey duration, and a link to the online survey. The first page of the survey described the study, its purpose, and advised

1
2
3 readers that continuing to the next page would be an indicator of consent to participate in the study.
4
5 All participants who completed the online survey were reimbursed by ISO 26362 as per industry
6
7 requirements. Representative sampling for key demographics of the Australian population was done
8
9 using quota sampling for age, sex, and residential location (state/territory and remoteness area)
10
11 with quota's set to reach the maximum numbers as indicated by the proportion shown for the usual
12
13 Australian population in Table 1. After 4 days of recruitment and from then on approximately
14
15 weekly, the demographics (age, sex, and broad location of residence (state/rurality)) of participants
16
17 with completed surveys were examined, and further sampling was targeted to underrepresented
18
19 groups to align with population characteristics. Non-responders characteristics were not collected as
20
21 this wasn't permitted by the sampling company in this study. In previous arms of the iCARE survey in
22
23 Australia the response rate was approximately 10% for new participants, which the sampling
24
25 company reported was typically expected for their online surveys of similar length (using only email
26
27 recruitment and electronic surveys). To minimise non-response bias, the sampling company would
28
29 send reminders to potential participants two times approximately one week apart (provided they
30
31 didn't belong to a quota that had been reached).
32
33
34
35
36
37
38

39 **Patient and public involvement**

40
41 As part of the main iCARE study, there are several community collaborators who provide continual
42
43 input into the development of the survey design, ensuring that the items are relevant and
44
45 appropriately worded. In addition, members of the general public have been engaged to contribute
46
47 to the dissemination of study results through sharable infographics made available on the study
48
49 website. For Australia, the survey was reviewed by the Monash Partners Consumer and Carer group
50
51 and involved two members paid for their time to identify text that wasn't clear or irrelevant to
52
53 Australia, and recommend alternative wording and areas to clarify. Other community members and
54
55 contacts of the researchers provided input into the timing to complete the survey, and subsequently
56
57 this feedback resulted in the survey being shortened to reduce participant burden.
58
59
60

Analysis Plan

Participant demographic data included residential postcode, which were mapped to the Australian Bureau of Statistics remoteness areas and socioeconomic index for areas (SEIFA) (28). Specifically, the index of relative socioeconomic disadvantage (IRSD) was applied and divided into five quintiles, from 1 (most disadvantaged) to 5 (most advantaged). Ethnicity information provided by participants was used to make two groupings of “Australian/New Zealand/UK” and everyone else.

Descriptive statistics reported the participant demographics and attitudes for a series of vaccine-related questions including the VCI (16, 21).

To characterise the beliefs, intentions and hesitancy of Australians towards vaccines generally and SARS-CoV-2 vaccines specifically, a series of univariate logistic regressions were done with dichotomous outcomes. Responses were dichotomised using the most extreme positive response e.g. “Always” vs other. To examine robustness, regressions were repeated by re-dichotomising outcomes to include the two most extreme responses instead of one. Unlike in similar analyses (21), our outcomes could not be examined using ordinal logistic regression because of low numbers in some response categories.

Possible predictors examined in the logistic regressions, included age, sex, essential worker status, belief that a participant is at high risk, residential area, flu vaccination status, education level, ethnicity, perceived income level, and IRSD quintile. Ethnicity data was missing for n=431 participants, therefore, these results were exploratory only. Responses to the VCI questions were also examined. All results are displayed as odds ratios, with 95% confidence intervals.

Sensitivity analyses involved Bayesian logistic regression to enabled global comparisons with a recent Lancet publication (21), and were conducted on the same outcome variables as in the logistic regressions. Normal priors (0,1) were set for each regression parameter and used 5,000 burn-in steps and 50,000 sampling iterations. Statistical analyses used STATA SE/v16. Significance level was set as <0.05.

Results

1
2
3
4 There were 1166 survey respondents in this cross-sectional analysis. Response rate was
5
6 approximately 10% for new participants and 60% for those in the longitudinal arm (27). Ages ranged
7
8 from 18-90 years with a mean of 51.7 years (table 1), similar to the Australian population, apart from
9
10 an overly represented group of participants aged 70 years or more. Sampling ensured a reasonable
11
12 representativeness across sex, rurality and the three largest states (New South Wales, Victoria and
13
14 Queensland). Education levels were similar to the Australian population. Less than half of
15
16 participants (45%) were in full-or part-time work, lower than national statistics reported for the
17
18 same time period (63%), and likely due to the overly represented 70+ age group. Fifteen percent
19
20 reported being essential workers, with 7% healthcare workers. There was minimal missing data
21
22 (table 1), except for ethnicity, with 50% respondents identifying as Australian/UK/NZ (n=580), 13%
23
24 as other (n= 155) but 37% were missing (n=431).
25
26
27
28
29
30

31 Sixty-five percent of participants generally accept routine vaccines for themselves or for their
32
33 children, with 6% either rarely or never accepting vaccinations (table 2). At the time of this study,
34
35 only 27 (2%) participants had already received at least one dose of a COVID-19 vaccination. The
36
37 majority (78%) reported that they were likely to get the SARS-CoV-2 vaccine (table 2), and fifteen
38
39 percent of all participants were either unlikely or very unlikely to get the SARS-CoV-2 vaccine.
40
41 Seventy-two percent of our study cohort did not believe that there were at a high risk of being
42
43 infected with COVID-19.
44
45
46
47
48

49 The VCI questions showed most Australians (>60%) strongly agreed on the safety, importance, and
50
51 effectiveness of general vaccines (figure 1). Fifty-seven percent strongly agreed that general vaccines
52
53 are compatible with their religious beliefs (figure 1). Approximately ten percent of participants did
54
55 not know whether vaccines are safe or effective (figure 1).
56
57
58
59
60

Predictors for vaccine uptake

Determinants that were similar for both general (Table 3) and SARS-CoV-2 vaccine uptake intention (Table 4) included:

Higher likelihood of vaccine uptake was significantly associated with:

- Increasing age with Odds Ratio (OR) = 1.6 (95% Confidence Interval: 1.4-1.8) and 2.0 (95% CI: 1.8-2.3) for general and SARS-CoV-2 vaccine respectively; residing in the least disadvantaged areas SES quintile (OR = 2.1 (95% CI: 1.4-3.2) and 2.7 (95% CI: 1.5-3.4) for general and SARS-CoV-2 vaccines).
- Identifying as Australian/NZ/UK with an OR = 2.3 (95% CI: 1.6 - 3.3) and 1.9 (95% CI: 1.3 – 2.7) for general and SARS-CoV-2 vaccines; however, as noted there was much missing data for the ethnicity variable, therefore this result is considered exploratory only.
- Strong agreement with the VCI questions. For example, strong agreement with the statement “Vaccines are effective” had an OR = 14.6 (95% CI: 10.9 – 19.5) for general vaccine and 14.0 (95% CI: 10.4 – 18.9) for SARS-CoV-2 vaccine.

Lower likelihood of vaccine uptake was significantly associated with:

- Being a healthcare worker: With an OR of 0.5 (95%CI: 0.3 – 0.8) and 0.5 (95%CI: 0.3 – 0.8), for general and SARS-CoV-2 vaccines, respectively. However, this is exploratory only due to the small sample of healthcare workers and inability to delineate what worker type (e.g. allied health, medical, social worker, etc.)

There were no significant findings for educational level, perceived income or residential rurality.

Differences between the general vaccines and the new COVID vaccines:

- There were no differences between the sexes for the likelihood of general vaccine uptake, whilst SARS-CoV-2 vaccine intention to uptake was significantly higher for men compared with women with OR of 1.37(95% CI: 1.08 – 1.72).

Factors that might influence decisions to get the SARS-CoV-2 vaccine:

1
2
3 Having information that the SARS-CoV-2 vaccine is safe (85%), effective (85%), will help protect
4 people around the participant (80%), and trusting the company who developed the vaccine (78%)
5
6 were reported to influence the participants somewhat or to a great extent to get vaccinated (Table
7
8 4). A doctor's recommendation (72%) and convenience factors (72%) were also positive predictor
9
10 variables for vaccine uptake. Other positive predictors include believing that the participant was at
11
12 high risk of getting COVID-19 or suffering from severe complications (69%), increasing civil liberties
13
14 (68%), and seeing others get vaccinated (66%).
15
16
17
18
19
20

21 **Sensitivity analyses:**

22
23 Bayesian regression analyses produced very similar results to initial logistic regression analyses. The
24
25 regressions repeated with re-dichotomising outcomes to include the two most extreme responses
26
27 instead of one, showed similar findings (supplementary table).
28
29
30
31
32
33

34 **Discussion**

35
36
37 We examined the beliefs, intentions, and hesitancy of 1166 Australians towards vaccines in general
38
39 and to the SARS-CoV-2 vaccine in a large, nationally representative cross-sectional analysis of a
40
41 surveys in early 2021. Seventy-eight percent of all participants reported being likely to get the SARS-
42
43 CoV-2 vaccine when it became available to them. Rates of both general vaccine uptake and SARS-
44
45 CoV-2 vaccine uptake increased with age, believing that vaccines are safe and effective, and residing
46
47 in the least disadvantaged socioeconomic region. Being male was associated with higher intentions
48
49 to get the SARS-CoV-2 vaccine but had no statistically significant difference to general vaccine
50
51 intention compared with females. There were no statistically significant differences in education
52
53 level, perceived income level or rurality and rates of either general or SARS-CoV-2 vaccine
54
55 acceptance. Strong influencing factors reported to convince people to uptake the SARS-CoV-2
56
57 vaccine were; knowing that the SARS-CoV-2 vaccine is safe and effective; trusting the vaccine
58
59
60

1
2
3 producers; knowing it will help protect people close to them; recommendations from doctors to get
4 vaccinated; and convenience getting the vaccine.
5
6
7
8
9

10 A 2021 study exploring global trends in SARS-CoV-2 vaccine hesitancy found that males, older adults,
11 those with a history of influenza vaccination were less likely to report hesitancy, echoing the findings
12 in our study.(29) They also found that those living in urban regions and that those who were in the
13 middle or top tiered of perceived income were less likely to be vaccine hesitant, with our study
14 finding no significant relationship between these variables. (29) Fifty-three percent of participants in
15 our study indicated that they were extremely likely to get a SARS-CoV-2 vaccine, which was lower
16 than those reported in Brazil (89%), Italy (81%) (Canada (71%) and the UK (80%), but similar to the
17 US (57%) and higher than Turkey and France (49% for both). (29)
18

30 The following factors were identified as having more of an influence on vaccination rates, and hence
31 could be used to inform public health policies and messaging to enhance vaccination rates. Having
32 knowledge that the SARS-CoV-2 vaccine is safe and effective will encourage a large proportion of the
33 study cohort to get vaccinated. These two factors are encompassed in the VCI and were recently
34 examined in a large international study (21). Together, they are likely to play the largest role in the
35 uptake of the SARS-CoV-2 vaccine. Responsible, accurate reporting of the balance of risks and
36 benefits in the media and social media is likely important to build trust in the vaccines and the
37 companies that manufacture them (30). Since trust in the vaccine companies is identified as a strong
38 influencing factor in encouraging vaccination, this needs to be reaffirmed by focusing on the
39 stringent regulatory processes the companies must adhere to, which can be conveyed in consistent
40 and transparent public health messaging. Participants also indicated that knowing that the SARS-
41 CoV-2 vaccine would protect those around them, was a significant factor influencing intention to
42 vaccinate. Whilst those who are vaccinated can still transmit SARS-CoV2, transmission is decreased
43 meaning family and friends are more protected, (31) which appeals to pro-social or altruistic
44
45

58
59
60

1
2
3 attitudes, known to effectively increase vaccination rates (32). Another key driver of vaccine uptake
4
5 likelihood in our study was getting a recommendation from a doctor, aligned with previous
6
7 immunisation programs, including in the H1N1 pandemic, and should be encouraged with the SARS-
8
9 CoV-2 vaccine (24). Medical professionals will benefit from consistent updated access to accurate
10
11 information on the SARS-CoV-2 vaccine, countering non evidence based anti-vaccination messages,
12
13 outlining benefits and risks, interpreting evidence as it emerges and personalising it to the
14
15 individuals who seek care (24, 33).
16
17
18
19
20

21 Convenience factors such as time needed or travel requirements to get vaccinated have also been
22
23 identified as a strong influencing factor. This could be why increased local vaccination sites in
24
25 Australia, including popup clinics at areas such as schools and mosques and shopping centres,
26
27 alongside the rollout of mass vaccination hubs, and of vaccinations to GP clinics, pharmacies, , and
28
29 workplaces, already shown to increase the rate of other vaccinations including the annual influenza
30
31 vaccine have also assisted in boosting Australia's vaccination rates for COVID-19 (34). Here 68% of
32
33 participants noted intention to get vaccinated if it offered them increased civil liberties, such as
34
35 going to concerts or sporting events.
36
37
38
39
40

41 When choosing to get vaccinated, the perceived likelihood of infection, the prevalence and severity
42
43 of the relevant disease are key in the decision making process (35). In early 2021 in our study, 72% of
44
45 all participants did not believe that they were at a high risk of getting COVID-19, likely reflecting the
46
47 low numbers of infections, hospitalisations and deaths in Australia at that time (36). Misinformation
48
49 in the media also equated COVID-19 severity to that of the seasonal flu (37). These factors are likely
50
51 to have presented obstacles to initial vaccination uptake in Australia, with participants who
52
53 perceived a higher risk of getting COVID-19 reported a 50% higher likelihood of getting vaccinated.
54
55
56 Previous research on the SARS-CoV-2 vaccine, as well as vaccination research during the 2009 H1N1
57
58 pandemic echo our results (33, 38). Leveraging anticipated regret, shown to be one of the strongest
59
60

1
2
3 predictors for vaccine intention, could also be further explored to enhance SARS-CoV-2 vaccination
4 rates. (33, 39) Consistent with other early surveys (40), we noted that men report the most
5
6 willingness to receive a SARS-CoV-2 vaccine, however, this intention may not translate to gender
7
8 differences in vaccination uptake (41).
9

10
11
12
13
14 Exploratory findings based on a small sample, suggested that healthcare workers and those not
15
16 identifying themselves being from Australia/NZ/UK were less likely to accept both general and the
17
18 SARS-CoV-2 vaccines. Considering the influence that healthcare workers have on the general
19
20 population, their high exposure rates this presents a barrier to both effective vaccine uptake and to
21
22 infection rates control. A 2021 review found an average of 23% (range: 4% to 72%) of healthcare
23
24 workers reported vaccine hesitancy. The review also found that being male, older and a doctor were
25
26 associated with higher rates of SARS-CoV-2 vaccine acceptance in healthcare workers (42). The
27
28 current study did not delineate between types of healthcare workers (e.g. doctors, nurses, allied
29
30 health).. Our findings also identified a higher rate of vaccine hesitancy in people who did not
31
32 identify their ethnicity as Australian/New Zealanders or UK groups, consistent with past research in
33
34 this and other vaccines (33). However, the findings for both these high-risk groups need to be
35
36 interpreted with caution due to the small sample size. More data here could aid in further targeting
37
38 policy-based communications and interventions.
39
40
41
42
43
44

45
46 Public health authorities need to provide transparent, easy to interpret information on the SARS-
47
48 CoV-2 vaccines to the general population, as highlighted by Eastwood et al during the H1N1
49
50 pandemic (43). This will aid in alleviating the confusion which may stem from misinformation
51
52 present in the media and online networks. Furthermore, we echo the suggestions made in Seale et
53
54 al., which includes tailoring messages and engaging community leaders in disseminating information
55
56 about vaccines in culturally and linguistically diverse groups, with the known influence of social
57
58 groups and community leaders of similar backgrounds (44). For healthcare workers, engagement
59
60

1
2
3 and education is important, given the important role they play in modelling health-promoting
4 behaviour for the general public (37). Mandatory influenza vaccination is already in place for many
5 healthcare workers in Australia, and mandatory SARS-CoV2 vaccination has been introduced for
6 aged care workers and for healthcare workers in all states and territories (42). This may have
7 contributed to increased vaccine uptake with recent government figures indicating that in the
8 majority of regions $\geq 90\%$ of aged care workers are fully vaccinated (45). Further, anecdotally it
9 appears that the majority of those working in other health facilities have been vaccinated with
10 minimal numbers standing down for refusing the SARS-CoV2 vaccine since the mandatory policy was
11 introduced. Healthcare workers beliefs and attitudes to the SARS-CoV2 vaccine may reflect similar
12 concerns to their broader community as seen in the UK with hesitancy being more frequent in non-
13 white British healthcare workers, female sex, and younger age (46). Understanding the impact of
14 mandates, knowledge, attitudes and beliefs driving this behaviour remains important given the risks
15 to staff and patients and the need for booster (or third dose) vaccines in the ongoing pandemic.

33

34 The strengths of our study include a large, generally representative sample across Australia and
35 evidence based approaches including the vaccine confidence index. Limitations to our study include
36 that this the survey was only available in English, which is likely to have reduced representation of
37 ethnic groups. Internet access was required, which may account for the increased representation of
38 those in the least disadvantaged quintile. Future studies should address these issues in order to
39 characterise vaccine intentions and attitudes in more remote and higher risk groups. Furthermore,
40 since we rely on self-reported behaviour, there is the risk of a social desirability bias, with
41 participants potentially over-reporting socially desirable traits in their responses and the voluntary
42 nature of the survey makes it prone to a selection bias (9, 47). Also the response rate of 10% for new
43 participants is a limitation that possibly introduced non-responder bias, and further studies with
44 greater resources to limit this bias by employing additional strategies such as telephone recruitment
45 and hard copy surveys could be conducted (48).

There is a paucity of studies on what influences people to consider taking the vaccine in Australia in 2021, where access to the SARS-CoV-2 vaccines is increasing, but still limited by age and occupation at the time of the survey. Since this survey, the rapid emergence of the highly transmissibility Delta variant, the major challenges of large scale, extended lockdowns escalating the imperative for rapid vaccination, and highlighting the importance of work in this field. Behavioural research such as the iCARE study can inform policymakers in understanding the public's knowledge, attitudes, perceptions and beliefs towards the SARS-CoV-2 vaccine, which in turn drive their behaviours including vaccination and can aid with targeting public health messages (24).

Conclusion:

Given the worldwide morbidity, hospitalisation, and death from COVID-19, the established safety and effectiveness of widely tested vaccines to prevent these complications, and the imperative to accelerate vaccination globally including in Australia, the results of this study on vaccine hesitancy are important. Here we show that vaccine safety, effectiveness, trust in the companies, and recommendations from doctors are important determinants of vaccine intentions. Further work to understand vaccine hesitancy in identified target groups including culturally and linguistically diverse groups and healthcare workers are important moving forward to support equity in vaccine uptake. This work can directly inform strategies to optimise communication and SARS-CoV-2 vaccine uptake, especially in Australia, now vital as the Delta variant takes a grip on the country.

Contributorship statement

SB and KL led study conceptualisation. JE, SD and JG were responsible for the statistical analyses. JG and JE wrote the first draft of the paper, with early input from DE. JB and HT are the senior authors and guarantors. All authors contributed to the development of the research question, study design in relation to the Australian data analysis, interpretation of the results, critical revision of the manuscript for important intellectual content, and approved the final version of the manuscript. JB attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Competing interests

SB has received consultancy fees from Merck for the development of behavior change continuing education modules, speaker fees from Novartis and Janssen and has served on advisory boards for Bayer, Sanofi and Sojecci Inc, none of which are related to the current article.

KL has served on the advisory board for Schering-Plough, Takeda, AbbVie, Almirall, Janssen, GSK, Novartis, Boehringer Ingelheim (BI), and Sojecci Inc, and has received sponsorship for investigator-generated research grants from GlaxoSmithKline (GSK) and AbbVie, speaker fees from GSK, Astra-Zeneca, Astellas, Novartis, Takeda, AbbVie, Merck, Boehringer Ingelheim, Bayer, Pfizer, Xfacto, and Air Liquide, and support for educational materials from Merck, none of which are related to the current article.

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Funding

The primary source of funding for the iCARE study has been provided by the Canadian Institutes of Health Research (MS3-173099, co-PI's: Simon L. Bacon & Kim L. Lavoie) and the Fonds de Recherche du Québec: Société et Culture (2019-SE1-252541, PI: Dr. Simon L. Bacon). Additional support has been provided through re-directed funding associated with Montreal Behavioural Medicine Centre, including funds from the Canada Research Chairs Program (950-232522, Chair holder: Dr. Kim L. Lavoie), a Canadian Institutes of Health Research-Strategy for Patient Oriented Research Mentoring Chair (SMC-151518, PI: Dr. Simon L. Bacon), a Fonds de Recherche du Québec: Santé Chair (251618, PI: Dr. Simon L. Bacon), and a Fonds de Recherche du Québec: Santé Senior Research Award (34757, PI: Dr. Kim L Lavoie). None of the funders were involved in the study design.

Data sharing statement

Data can be made available to approved researchers by contacting the corresponding author.

The iCARE study is an open access study. Data access procedures are available at <https://mbmc-cmcm.ca/covid19/apl/>. Planned analyses are logged at <https://mbmc-cmcm.ca/covid19/apl/log/>.

Ethics Approval Statement

The studies involving human participants were reviewed and approved by Monash University Human Research Ethics Committee (MUHREC Project ID: 24449). The patients/participants provided their written informed consent to participate in this study.

The Montreal Behavioural Medicine Centre, the lead institution, has research ethics board approval from the Comité d'éthique de la recherche du CIUSSS-NIM (Centre intégré universitaire de santé et de services sociaux du Nord-de-l'île-de-Montréal), approval#: 2020-2099/25-03-2020.

Acknowledgments

Dr. Lavoie is a member of the Canadian COVID-19 Expert Advisory Panel (Health Canada).

Tables and Figures

Figure Legend (Figure in separate 'image' file designation)

Figure 1: Vaccine Confidence Index: Responses to the questions about if general vaccines are safe, important, effective, and compatible with your religious beliefs.

Box 1. Vaccine hesitancy and confidence are complex and can be influenced by many determinants, as identified by the Strategic Advisory Group of Experts on Immunization (SAGE) working group on vaccine hesitancy.

Categories	Examples
Contextual socio-politico-cultural factors	- compatibility of vaccination with religious beliefs
Individual and group influences	- personal perception of the vaccine - influences from the social and peer environment
Vaccine specific factors	- issues directly related to the vaccine or vaccination - accelerated development of vaccines for SARS-CoV-2 may increase safety concerns in the population

Table 1: Participant demographics (n = 1166).

	Australian Population (% unless otherwise indicated)	Sample N (%) 1158
Age (mean, SD)	39	51.7, 19.3
Age (median, IQR)	38	53, 37.5
Age Breakdown¹ (%)		
18-29	19	214 (18)
30-39	19	175 (15)
40-49	17	142 (12)
50-59	16	148 (13)
60-69	14	143 (12)
70+	15	336 (29)
Sex¹ (%)		
Males	50	583 (50)
Females	50	572 (49)
Others/Prefers not to answer	0	8 (0.7)
Area of residence² (%)		
Urban/City/Suburban/Regional	90	979 (87)
Rural/Country	10	142 (13)

Quintile 4	20	238 (20)
Quintile 5 – least disadvantaged	20	345 (30)
Ethnicity⁴ (%)		
Australian/New Zealand/UK	73	580 (50)
Other	27	155 (13)
Missing	-	431 (37)
Where applicable, variable categories have been collapsed to allow for concordance with national data published by the Australian Bureau of Statistics (ABS):		
1: The total Australian population was 25,704,340 as of March 2021; the total population and percentage breakdowns by age, sex, and state of residence are obtained from the Australian Bureau of Statistics, (49) who provide a quarterly release of their official estimates of this demographic data. Age is presented in 10-		

1
2
3 year bands, and the first band that is comparable to the current study is 20-29 years. The proportion of
4 Australians by age is calculated as the proportion of those 20 or over.

5 2: Estimates for percentage of population by area of residence were obtained from the ABS, who release this
6 data yearly. (50)

7 3: Estimates for the percentage of population by level of education were obtained from the ABS, who release
8 this data yearly.(51)

9 4: National estimates for ethnicity were obtained by assessing the “country of birth” data provided by the ABS
10 2016 Census. Whereas the survey ‘ethnicity’ variable was created using survey responses to the ethnicity item.

Table 2: Uptake intentions and attitudes on general vaccines and COVID-19 vaccine, and intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post COVID-19 vaccine.

	N (%)
Had already received at least 1 dose of COVID-19 vaccine	27 (2)
Likelihood of getting COVID-19 vaccine if it were available today	
Extremely likely	597 (53)
Somewhat likely	283 (25)
Unlikely	88 (8)
Very unlikely	83 (7)
I don't know/prefer not to answer	80 (7)
Generally accept vaccines for yourself or for your children	
Always	736 (65)
Mostly	232 (21)
Sometimes	100 (9)
Rarely	41 (4)
Never	21 (2)
Intent to continue engaging in virus-protecting behaviours (mask wearing, social distancing etc.) post vaccine	
Most of the time	526 (47)
Some of the time	343 (31)
Seldom	94 (8)
Never	54 (5)
I don't know/prefer not to answer	95 (9)
Seasonal flu vaccine over the last 5 years	
Every year	511 (46)
3-4 years	163 (15)
1-2 years	202 (18)
Never	218 (19)
I don't know/prefer not to answer	27 (2)

Table 3: Vaccine uptake determinants: Univariate regression analyses with possible predictors that influence general vaccine uptake (left columns) and SARS-CoV-2 vaccine uptake(right columns) . *Age variable is scaled to have a mean of 0 and unit standard deviation. **Ethnicity data was missing for n=431, therefore results for this variable are exploratory only.

	Do you generally accept vaccines for yourself or for your children?				If a vaccine for COVID-19 were available today, what is the likelihood that you would get vaccinated?				
	Outcome: "Always" vs not				Outcome: Extremely likely v. Not				
	OR	95% confidence interval		P	OR	95% confidence interval		p	
Vaccines confidence (strongly agree v not strongly agree)

Table 4: Factors reported by n=1,081 Australians that may influence intent to get the SARS-CoV-2 vaccine. *Combined 'somewhat' and 'to a great extent' responses. Influencing factors are ranked in descending order, from most likely to influence SARS-CoV-2 vaccine uptake to least likely.

N (row %)	Combined strongest likelihood *	To a great extent	Somewhat	Very Little	Not at all	I don't know	Total
Having information that the vaccine is safe and unlikely to have any major long- term side effects	921 (85)	661 (61)	260 (24)	78 (7)	50 (5)	32 (3)	1,081
Having information that the vaccine is effective (i.e., provides a high degree of protection)	913 (85)	661 (61)	252 (23)	78 (7)	58 (5)	31 (3)	1,080
Knowing that getting vaccinated will help protect others around me	858 (80)	548 (51)	310 (29)	107 (10)	72 (7)	36 (3)	1,073
Trusting the company who developed the vaccine (Pfizer, Moderna, Sinopharm, etc.)	839 (78)	474 (44)	365 (34)	112 (10)	75 (7)	50 (5)	1,076
Receiving the vaccine dose(s) according to the manufacturers' instructions	818 (76)	505 (47)	313 (29)	122 (11)	90 (8)	42 (4)	1,072
Wanting to contribute to high population rates of vaccination to achieve 'herd immunity'	791 (74)	476 (44)	315 (29)	131 (12)	101 (9)	52 (5)	1,075
The convenience of getting the vaccine (e.g., requires little time, no need to travel far)	772 (72)	417 (39)	355 (33)	143 (13)	118 (11)	42 (4)	1,075
Getting a recommendation from my doctor to get vaccinated	774 (72)	438 (41)	336 (31)	163 (15)	97 (9)	37 (3)	1,071
Believing that I am high risk of getting COVID-19 or suffering severe complications	729 (69)	361 (34)	368 (35)	175 (17)	119 (11)	37 (3)	1,060
Learning that being vaccinated would allow me to attend public events (e.g., concerts, sporting events) or travel	734 (68)	422 (39)	312 (29)	179 (17)	121 (11)	39 (4)	1,073
Seeing more and more people getting the vaccine	708 (66)	335 (31)	373 (35)	191 (18)	135 (13)	34 (3)	1,068
Hearing that other people have positive attitudes towards the vaccine	687 (64)	306 (29)	381 (36)	195 (18)	151 (14)	35 (3)	1,068
Only needing one dose of the vaccine to be protected	647 (61)	302 (28)	345 (32)	203 (19)	159 (15)	56 (5)	1,065
Believing that getting vaccinated would reduce my worries and anxiety	635 (60)	273 (26)	362 (34)	225 (21)	156 (15)	43 (4)	1,059
Getting a recommendation from my employer to get vaccinated	386 (52)	158 (21)	228 (31)	163 (22)	147 (20)	44 (6)	740

Supplementary 1: Vaccine uptake sensitivity analysis: Univariate regression analyses with possible predictors that influence general vaccine uptake (left columns) and SARS-CoV-2 vaccine uptake (right columns), using “Always/Mostly” and “Extremely/Somewhat likely” answer options. *Age variable is scaled to have a mean of 0 and unit standard deviation. **Ethnicity data was missing for n=431, therefore results for this variable are exploratory only.

	Do you generally accept vaccines for yourself or for your children?				If a vaccine for COVID-19 were available today, what is the likelihood that you would get vaccinated?			
	Outcome: “Always/Mostly” vs not				Outcome: Extremely/somewhat likely v. not

Australian arm of International COVID-19 Survey WAVE 3

Start of Block: Introduction

We are inviting you to complete this short 10-15 minute survey every couple of months, and the questions may change depending on new issues arising during the COVID-19 pandemic. You are welcome to complete only the surveys that you wish and by completing one survey does not mean that you have to do further surveys. You are free to withdraw at any time and you can choose not to answer any specific questions. If you have participated via an invitation from the Online Research Unit, then your previous surveys may be linked in a privacy preserving manner whereby you cannot be identified. We will not be collecting any information that we can use to identify you, so your responses remain completely anonymous.

We are the Australian arm of a group of over a 120 researchers from more than 30 countries. We are researchers at the Monash Centre for Health Research and Implementation at Monash University (<https://www.monash.edu/medicine/sphpm/mchri/mchri>). For this COVID-19 survey study we are affiliated with the Montreal Behavioural Medicine Centre (www.mbmc-cmcm.ca) and University of Quebec at Montreal and Concordia University in Canada. We want to understand people's awareness, attitudes, beliefs, and behaviours around COVID-19, which is also known as coronavirus or novel coronavirus, throughout the world. We also want to know how the pandemic is affecting different aspects of people's lives. To do this we are asking people from different countries to complete this survey. We also want to have a variety of different views, so anyone can complete the survey, no matter what your age, sex, or background is.

The survey will require about 15 minutes to complete. Please make sure you give yourself enough time, as you cannot save the survey and come back to it later. There are no risks associated with your participation to this study.

All data will be securely collected on servers at Monash University (Australia) and University of Quebec at Montreal (Canada). Respecting international data sharing agreements supported by the Fonds de la recherche du Québec (FRQ), the data from this study will be made available to study collaborators.

Researchers in the future will be able to request data access, in which case a data sharing agreement form will need to be signed alongside the lead researchers, and data provided will be anonymous. All copies of the study data will be stored on secure, password protected servers that can only be accessed by authorized individuals.

Start of Block: B. REACTIONS TO COVID-19

B. REACTIONS TO COVID-19 Different people, organizations, governments, and health authorities have recommended people do a variety of things to reduce and slow the spread of COVID-19 in the population.

For peer review only

BMJ Open: first published as 10.1136/bmjopen-2021-057127 on 3 January 2022. Downloaded from <http://bmjopen.bmj.com/> on April 19, 2024 by guest. Protected by copyright.

11. For each of the following, please indicate what actions or behaviours your **government or local health authority has recommended**.

	Yes (1)	No (2)	I don't know/I prefer not to answer (3)
Hand washing with soap and water for 20 seconds (1)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Wearing a face mask in indoor spaces (shops, restaurants, public transit, at work) (3)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Wearing a face mask outside (7)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Staying at least 1-2 metres away from other people (8)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Staying/working at home rather than going to work or school (9)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Self-quarantining if you are returning from a trip (14)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Self-quarantining if you have or believe you have the virus (10)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Avoiding going out to bars/pubs/restaurants (17)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Avoiding large social gatherings (18)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Avoiding small social gatherings (19)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Avoiding indoor social gatherings (20)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Avoiding any non-essential travel (21)	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>

1
2
3
4
5
6
7 12. To what extent do you believe that the measures asked of you by your government or local
8 health authority **are important** to prevent and/or reduce the spread of COVID-19?
9

- 10
11 Very important (1)
12
13 Somewhat important (2)
14
15 Not very important (3)
16
17 Not important at all (4)
18
19 I don't know/I prefer not to answer (5)
20
21
22
23

24
25
26 13. a) What do you think of the **actions taken** by your government or local health authority to
27 prevent and/or reduce the spread of COVID-19?
28

- 29
30 Too strict (1)
31
32 About right (2)
33
34 Too lenient (3)
35
36 I don't know/I prefer not to answer (4)
37

54
55
56
57
58
59
60

1
2
3 13. b) How likely are you to download and install a **government COVID-19 tracing app** on your
4 phone?
5

- 6
7 Extremely likely (1)
8
9 Somewhat likely (2)
10
11
12 Unlikely (3)
13
14 Very unlikely (4)
15
16
17 I don't know/I prefer not to answer (5)
18
19
-

20
21
22 14. Do you think your government or local health authority's actions are motivated by:
23

- 24
25 Mainly protecting people's health related to COVID-19 (1)
26
27 Generally protecting people's health related to COVID-19 and a little bit on protecting the
28 economy (2)
29
30 Generally protecting the economy and a little bit on protecting people's health related to
31 COVID-19 (3)

3 57. Prior to the COVID-19 pandemic, how would you best describe your primary **job sector**?

- 4
5
6 Professional (health, physical/earth science/engineering professionals,
7 teacher/university professor, business/sales and marketing professional, software
8 developer, legal, clergy, author, journalist, performing artist) (1)
9
10 Manager (chief executive, administrative manager, production and sales, hospitality and
11 retail manager) (2)
12
13 Technician or associate professional (in field of health, engineering, business, legal,
14 social, or information/communications) (3)
15
16 Clerical support worker (office clerk, secretary, customer service clerks) (4)
17
18 Service and sales worker (travel agent, cook, hair dresser/barber, retail sales, cashier,
19 personal care worker) (5)
20
21 Skilled agricultural, forestry and fishery worker (6)
22
23 Craft and related trades worker (builders, machinists, electricians, printing, food
24 processing) (7)
25
26 Plant and machine operator and assembler (includes truck drivers) (8)
27
28 Elementary occupations (cleaner, helper, agricultural laborer, transport laborer, street
29 vendor, refuse worker) (9)
30
31 Armed forces occupations (commissioned and non-commissioned) (10)
32
33 Other (11)
34
35 I don't know/I prefer not to answer (12)

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	1,2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-6
Objectives	3	State specific objectives, including any prespecified hypotheses	6
Methods			
Study design	4	Present key elements of study design early in the paper	7
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	7
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	7
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	8
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	8-9
Bias	9	Describe any efforts to address potential sources of bias	8
Study size	10	Explain how the study size was arrived at	7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	9
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	8
		(b) Describe any methods used to examine subgroups and interactions	8
		(c) Explain how missing data were addressed	10
		(d) If applicable, describe analytical methods taking account of sampling strategy	N/A
		(e) Describe any sensitivity analyses	9
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	9
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	N/A
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	9
		(b) Indicate number of participants with missing data for each variable of interest	10
Outcome data	15*	Report numbers of outcome events or summary measures	10-11
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Table 3

		(b) Report category boundaries when continuous variables were categorized	Table 1
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	11
Discussion			
Key results	18	Summarise key results with reference to study objectives	12
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	15
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	12-15
Generalisability	21	Discuss the generalisability (external validity) of the study results	15
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	N/A

*Give information separately for exposed and unexposed groups.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
