ABSTRACT

Introduction Postoperative pain remains a challenging medical condition impacting the quality of life of every patient. Although several predictive factors for postoperative pain have been identified, an adequate prediction of postoperative pain in patients at risk has not been achieved yet. The primary objective of this study is to identify specific genetic risk factors for the development of acute and chronic postoperative pain to construct a prediction model facilitating a more personalised postoperative pain management for each individual. The secondary objectives are to build a databank enabling researchers to identify other risk factors for postoperative pain, for instance, demographic and clinical outcome indicators; provide insight into (genetic) factors that predict pharmacological pain relief; investigate the relationship between acute and chronic postoperative pain.

Methods and analysis In this prospective, observational study, patients who undergo elective surgery will be recruited to a sample size of approximately 10 000 patients. Postoperative acute and chronic pain outcomes will be collected through questionnaires at different time points after surgery in the follow-up of 6 months. Potential genetic, demographic and clinical risk factors for prediction model construction will be collected through blood, questionnaires and electronic health records, respectively.

Genetic factors associated with acute and/or chronic postoperative pain will be identified using a genome-wide association analysis. Clinical risk factors as stated in the secondary objectives will be assessed by multivariable regression. A clinical easy-to-use prediction model will be created for postoperative pain to allow clinical use for the stratification of patients.

Ethics and dissemination The Institutional Review Board of the Radboud university medical centre approved the study (authorisation number: 2012/117). The results of this study will be made available through peer-reviewed scientific journals and presentations at relevant conferences, which will finally contribute to personalised postoperative pain management.

Trial registration number NCT02383342.

STRENGTHS AND LIMITATIONS OF THIS STUDY

⇒ This is a large prospective study to identify genetic and other risk factors for postoperative pain.
⇒ We will build a databank with comprehensive interdisciplinary measurements that assess postoperative pain from multiple perspectives.
⇒ Outcome measurements of pain by patient-reported outcomes, rather than evaluated by professionals.
⇒ The investigating biomarkers of postoperative pain are limited to genetic variants.

INTRODUCTION Pain after surgery remains a challenging medical and societal problem.1 Pain is one of the most common postsurgical side effects, with moderate to severe acute postoperative pain occurring in about 41% of the patients.2–4 Severe postoperative pain is associated with an increased incidence of postoperative complications,5 including prolonged hospital stay, readmissions and significant reduction of patient satisfaction and quality of life.6–7 In addition, acute postoperative pain is associated with chronic pain development after surgery.8 A recent position paper from the International Association for the Study of Pain (IASP) stated that among the almost 40 million people undergoing surgery globally each year, 1 out of 10 develops chronic postsurgical pain (CPSP), and 1 out of 100 suffers from severe CPSP, which will negatively affect patients’ quality of life.9 In addition, postoperative pain is a considerable burden on healthcare service costs, both directly due to patients’ increased consumption of medical care and indirectly due to absenteeism, reduced productivity and increased social welfare payments.10–15

The management of both acute postoperative pain2,6,16 and CPSP2,17 has remained suboptimal. Despite major investments in clinical protocols and guidelines for structural pain management, infrastructure and acute pain services, no significant outcome
improvements in the quality of postoperative pain management for individual patients have been achieved in the last 15 years.\(^\text{10,11}\)

Given the high incidence of postoperative pain, identifying patients at risk for CPSP before the operation is important to apply more personalised pain prevention strategies. The most important demographic and clinical risk factors for postoperative pain are younger age, female sex, smoking, history of depressive symptoms, anxiety symptoms, sleep difficulties, higher body mass index (BMI), presence of preoperative pain and use of preoperative analgesics.\(^\text{18}\) Based on these factors, models have been developed to predict severe acute postoperative pain\(^\text{19,20}\) and CPSP.\(^\text{21,22}\) A recent study has evaluated a presurgical risk score for CPSP in a prospective cohort, and it reliably identified about 70% of the patients undergoing surgeries at risk of CPSP.\(^\text{23,24}\)

As a multifactorial trait, the incidence variation of CPSP in the population can be explained partly by the demographic and clinical risk factors mentioned above, and partly due to the genetic and epigenetic differences among patients.\(^\text{25,26}\) To improve the accuracy and power of prediction, efforts have been made to predict CPSP using genetic variants.\(^\text{21,24}\) However, no unequivocal genetic predictors have been found yet. In addition, many exploratory studies investigated the possible role of candidate genes in postoperative pain development. In particular, associations have been found between CPSP and the \(\mu\)-opioid receptor (\(\text{OPRM1}\)) and catechol-O-methyl transferase (\(\text{COMT}\)) genes.\(^\text{27,28}\) Still, these results have not been confirmed by others. \(\text{OPRM1}\) is also associated with basal pain sensitivity differences,\(^\text{29}\) which could be caused by the altered opioid binding potential in the central nervous system.\(^\text{30}\) More recently, hypothesis-free methods, such as Genome-Wide Association (GWA) studies (GWAS), have been applied for CPSP to identify markers across the genome.\(^\text{31,32}\) One of the studies showed that a genetic variant in the \(\text{protein-kinase C}\) gene is linked to neuropathic pain after complete joint replacement. This gene is involved in long-term potentiation, synaptic plasticity, chronic pain and memory, indicating that this gene may be relevant for neuropathic pain initiation. The disadvantage of this study is that it was small in terms of patient numbers and only focused on one specific surgical procedure.

Besides genetic variants for altered pain sensitivity, gene variants in drug metabolism can also play a role. Understanding the reasons for ineffective treatment can facilitate the early identification of patients at risk and provide more effective and customised postoperative management. Some associated genes with pain treatment outcomes are also involved in pain development, such as \(\text{COMT}\).\(^\text{33-35}\) Genes involved in the action site of active drugs or the drugs’ metabolism might play a role in the therapeutic response of this drug. A well-known example is the \(\text{cytochrome P450 (CYP)}\) family investigated for several drugs (eg, codeine and tramadol).\(^\text{36}\) However, this area has never been charted in a large population.\(^\text{37}\)

To date, adequate prediction of patients at risk for postoperative pain in clinical practice has not been achieved for several reasons. First, although many demographic, clinical and lifestyle factors of postoperative pain have been reported,\(^\text{38}\) a lack of consensus on the best outcome indicators for postoperative pain management\(^\text{38,39}\) hinders choosing the proper outcome variables for prediction model construction. Second, the potential genetic risk factors of postoperative pain prediction remain obscure. The role of genetic factors in postoperative pain have not been investigated sufficiently, making it challenging to select appropriate genetic risk factors to construct a prediction model. Third, when prediction models are updated, external validation (ie, in a new population) is important before being implemented in a clinical setting,\(^\text{40-43}\) which is often difficult due to the lack of validation cohorts. For these reasons, we hypothesise that a global structural multicentre diagnostic programme of postoperative pain in a surgical patient population will be valuable for better identifying patients at risk of CPSP and ultimately preventing postoperative pain using individualised pharmacological and non-pharmacological interventions.

**Objectives**

The primary objective of the Pain Predict Genetics (PPG) study is to identify genetic risk factors for acute and chronic postoperative pain development and to construct a prediction model for personalised postoperative pain management.

The secondary objectives of the PPG study are to build a databank enabling researchers to (1) identify other risk factors for the development of acute and chronic postoperative pain; (2) provide insights into complications and other clinical outcome indicators after surgery; (3) provide insights into the relationship between acute and chronic postoperative pain and (4) identify (genetic) factors that predict pharmacological pain relief. The databank will be open to the public with access fees, and reasonable requests will be discussed in the research group before approval.

The extensive data collection on (chronic) postoperative pain development of patients undergoing surgery offers many possibilities for additional research questions using conventional statistical methods and artificial intelligence, for example, machine learning. The cohort could be used to (1) conduct epidemiological studies; (2) investigate other parameters (eg, types of surgery) that are involved in the development of chronic postoperative pain; (3) validate new prediction models for (chronic) postoperative pain; (4) identify factors for the postoperative outcome (for example, death, long-term hospitalisation, complications); (5) collaborate with other groups to perform large-scale analysis to identify predictors for the development of (chronic) postoperative pain.
METHODS AND ANALYSES

Study design
A prospective, observational study of 10,000 patients will undergo elective surgery. This study will run for at least ten years, during which period it must be possible to include the intended number of patients. Patient inclusion after CMO (Human Research Committee, in Dutch Commissie Mensgebonden Onderzoek) approval was started in March 2015, and patient inclusion was temporarily stopped in 2020 due to COVID-19 restrictions. In the near future, this study will be continued as a multicentre study; hospitals have already been approached and indicated that they intend to participate.

Patient and public involvement
During the design of the study, the patients aided in the pilot phase of the questionnaires; during the recruitment the patients are informed concerning the project. In addition, patient reported outcomes will be used. Patients will be informed about the outcome of the study at several moments (depending on the obtained results).

Participants
Patients who undergo elective surgery and are eligible for this study will be approached before their planned surgery during the preoperative consultation. In this way, potential participants will have sufficient time to consider the study information. If any questions arise, it is possible to contact the researchers by telephone or ask the questions during the preoperative consultation. During the preoperative consultation (outpatient clinic or by telephone), the physician (assistant) will ask the patient if they are interested to participating in the study. If the patient is willing to participate, the informed consent form will be signed and dated. If patients have an online preoperative consultation, this procedure will take place digitally, and patients receive the study forms (signed in advance) at home to return if they consent.

Patients are eligible for study inclusion if they (1) are older or equal to 16 years; (2) undergo elective surgery with an incision, including cardiothoracic surgery (eg, cardiomytomy), general surgery (eg, breast resection), neurological surgery (eg, nerve decompression), oral and maxillofacial surgery (eg, removal of head and neck benign and malignant tumours), otorhinolaryngology (eg, tympanoplasty), plastic surgery (eg, breast reconstruction), trauma and orthopaedic surgery (eg, arthroplasty), urology (eg, prostatectomy) and vascular surgery (eg, treatment of varicose veins); (3) can read and understand the patient information; (4) will provide informed consent. Patients will be excluded if they (1) intend to undergo another surgery within 6 months and (2) do not have enough knowledge of the language in words and understanding to complete questionnaires.

Measurements

Questionnaires
After written informed consent, participants will be asked to complete questionnaires before and after their surgery. An overview of the study workflow and data collection time points can be found in figure 1 and table 1. All patient data will be stored in an online digital database, Castor. The reliability and validity of all questionnaires for measurement collection have been validated in the corresponding populations.

The first digital questionnaire must be completed the day before the surgery (no longer than 1 week before). Before surgery, the following parameters will be collected (table 1, online supplemental file 1): demographic characteristics (such as gender, age, BMI), expected incision size in mm, pain intensity, pain disability, preoperative anxiety and need for information, pain catastrophising, pain sensitivity, preoperative chronic pain characteristics and depressive symptoms.

After surgery, the following parameters will be collected: actual incision size in mm on day 1; pain intensity on days 1, 2, 3, weeks 1 and 6, and months 3 and 6; physical activities on days 1, 2, 3, week 1; pain disability on weeks 1 and 6, and months 3 and 6; postoperative chronic pain characteristics on months 3 and 6; characteristics of pain on months 3 and 6.

Pain intensity will be measured with an 11-point Numerical Rating Scale (NRS) at rest and during a normal patient action at that time. The endpoints represent the

Figure 1 Pain predict genetics study design overview. After written informed consent, participants will be asked to complete questionnaires before and after their surgery. One tube of blood will be collected for DNA isolation using the intravenous line in place for surgery. Clinical information will be collected from the electronic patient file after the operation.
extremes of the pain experience: 0 means ‘no pain at all’ and 10 means ‘worst possible pain’.

Pain disability (disability associated with pain) will be measured by the widely used Pain Disability Index Dutch language version (PDI). The PDI is a seven-item questionnaire to investigate the magnitude of the self-reported disability in different situations such as work, leisure time, daily life activities and sports. The questionnaire is constructed on an 11-point NRS in which 0 means ‘no disability’ and 10 means ‘maximum disability’.

Preoperative anxiety and need for information will be evaluated by the Amsterdam Preoperative Anxiety and Information Scale (AP AIS). The AP AIS consists of six questions and each score on a five-point Likert scale from 1 (not at all) to 5 (extremely), with four questions to assess the patient’s preoperative anxiety score and two questions to assess the patient’s need for information regarding the scheduled surgery and anaesthesia.

Pain catastrophising is generally described as an absurd negative orientation towards hurtful stimuli and is important in pain coping. It will be measured by the Pain Catastrophising Scale, a self-evaluating questionnaire consisting of 13 questions. People are asked to indicate the degree to which they have thoughts and feelings when experiencing pain using the 0 (not at all) to 4 (all the time) scale, and a total score will be yielded (range from 0 to 52).

The Pain Sensitivity Questionnaire (PSQ) will measure patients’ preoperative pain sensitivity. The PSQ consists of 17 questions that describe daily life situations; respondents score their pain intensity for these situations on an NRS by scoring 0 (not painful) to 10 (severest pain imaginable).

The severity of overall depressive symptoms will be assessed by the Inventory of Depressive Symptomatology Self Report (IDS-SR). IDS-SR is a 30-item questionnaire, and each item has four statements scored on a four-point scale from 0 to 3. There are two items about either increasing or decreasing appetite and two items about increasing or decreasing weight. Only the item with the

higher score from both pairs will be chosen. The total score is based on 28 items and ranges from 0 to 84.

Physical activities (ability to perform normal activities) will be measured by questions assessing the degree of physical activities interfered by surgery, including bed activities (such as turning), breathing deeply of coughing, sleeping and activities out of bed. Each item is scored on an 11-point NRS in which 0 means did not interfere and 10 means completely interfered. These questions are derived from the validated International Pain Outcomes questionnaire and are found responsive to asking patients about their ability to perform normal activities directly after surgery.\(^5\)

Characteristics of pain will be measured by the Brief Pain Inventory-Short Form (BPI-SF), which is a shortened version of the BPI.\(^3\) BPI-SF evaluates pain severity during the past 24 hours and current level, with 0 representing ‘no pain’ and 10 ‘the worst pain imaginable’. Seven items in BPI-SF assess interference with daily functioning (such as general activity, walking and work) on an 11-point scale, where 0 represents ‘no interference’ and 10 ‘complete interference’.

**Collection of body material**

One tube of blood will be collected for DNA isolation. The burden for the patient is minimalised as blood will be taken using the intravenous line in place for surgery. If it is impossible to collect blood presurgically or postsurgically, we will collect saliva for DNA isolation (Genefix DNA saliva collectors; GFX-02/50, Isohelix).

**Clinical information**

The following clinical information will be collected from the electronic patient file six months after operation (table 1): physical status by The American Society of Anesthesiologists classification status; type of surgery; duration of surgery; type of anaesthesia; postoperative complications within 30 days after surgery, one-time retrospectively, which is defined as any medical adverse outcome occurring between admission and 30 days after operation. Complications occurring in the operation room and complications directly related to anaesthesia (eg, nausea which resolves immediately after medication in the operation room) will not be included.\(^5\)  \(^5\) Furthermore, data on pain medication use, before surgery and after surgery; actual incision size in mm; second surgery within 6 months; general clinical outcome indicators, including surgical site infection at 30 days, stroke within 30 days of surgery, death within 30 days of surgery, admission to the intensive care unit within 14 days of surgery, readmission to hospital within 30 days of surgery and length of hospital stay (with or without in-hospital mortality) will be collected.\(^5\)

**Outcome measures**

The outcome measures are acute postoperative pain and chronic postoperative pain. Acute postoperative pain is defined as pain experienced directly after surgery.

Thresholds or cut-off points of the pain intensity are set as none to mild (0–3), moderate (4–7) and severe (8–10).\(^5\)\(^5\) The definition of CPSP is in agreement with IASP terminology of CPSP, that is, ‘chronic pain that develops or increases in intensity after a surgical procedure persists beyond the healing process, that is, at least 3 months after the surgery’.\(^9\) CPSP will be measured by a chronic pain characteristics questionnaire postoperatively at 3 and 6 months. Patients will be asked to indicate whether they had a recent pain experience, the site of pain and whether it lasted more than 3 months.\(^5\)\(^8\) The intensity of CPSP will also be characterised by the pain scores questionnaire using the same threshold as acute postoperative pain. The influence of pain on functional and mood changes will be measured by the PDI and the BPI-SF.

**Sample size calculation**

The power of the genetic study is based on the primary research question investigating which genetic factors are associated with postoperative pain. Power is calculated using the Genetic Power Calculator,\(^60\) and the estimated number of patients is based on a GWA approach. For chronic postoperative pain, we assume a case-control analysis for discrete traits (2 df test), a risk allele frequency of 30%, a linkage disequilibrium (D’) of 0.8, a prevalence of chronic postoperative pain of 15%, and the relative risk of chronic postoperative pain for persons who are heterozygous of 1.5 and for homozygous persons of 2.25. For a power of 80% with a p value cut-off 5×10\(^{-8}\) (genome-wide significance threshold), we need 750 patients with chronic postoperative pain and 4250 people without chronic postoperative pain. For acute pain, the power is even higher. With the same population, we have more than 80% power to detect a relative risk of 1.2 and 1.44 for heterozygous and homozygous persons, respectively. This higher power is due to the higher prevalence of acute (moderate to severe) pain of 55%. Most importantly, results will be replicated in the additional study participants, as the total number of patients included in the study will be 10000. In addition, we will use cohorts of our collaborators for replication purposes.

**Statistical analysis**

The key objective is to identify genetic risk factors that can predict development of acute or chronic postoperative pain and validate previously reported SNPs. A GWA approach will be used as the main analysis. Phenotype data and DNA will be used to identify genetic factors. We will use 5000 patients for the discovery of genetic variants. Samples will be genotyped with the Infinium Global Screening Array (Illumina). Preimputation quality control, principal component analyses and imputation will follow the RICOPILI pipeline.\(^61\) Potential confounding by ethnic origin will be corrected by principal component analyses. The 1000 Genomes reference panel will be used for imputation, followed by postimputation quality control in PLINK.\(^52\) Associations between
SNPs and the presence of acute or chronic pain will be performed using cutting-edge methods when data collection is finished. Results will be replicated to ensure validity. SNPs that can be validated will be included in the prediction model described below.

Secondary objectives include identifying other potential risk factors for acute and chronic postoperative pain. Therefore, a univariate association of each potential predictor will be calculated and tested in a multivariable regression model. We will use a least absolute shrinkage and selection operator (LASSO) regression. Shrinkage is where data values are shrunk towards a central point, like the mean. LASSO is a regression analysis method that performs both variable selection and regularisation to enhance the prediction accuracy and interpretability of the statistical model it produces. After identifying these risk factors, a prediction rule will be created for (moderate to severe) acute and chronic postoperative pain. Based on this prediction rule, a simple, clinically easy applicable tool will be developed to allow clinical use for the stratification of patients. The predictive performance will be studied in another cohort of patients to test whether the rule is generalisable across time and place. Because it appears from the literature that acute and chronic pain are correlated after surgery, additional correlation analysis will be performed to investigate this correlation in the data.

Similar approaches will be followed to identify the clinical and genetic factors that predict pharmacological pain relief. For some pain medicines, genes that impact pain relief are already known (eg, CYP2D6 and morphine). We will first investigate those genes to see if these variants indeed contribute to pharmacological pain relief differences.

**Ethics and dissemination**

The study will be conducted according to the principles of the Declaration of Helsinki version 2013 and in accordance with the Medical Research Involving Human Subjects Act and Good Clinical Practice. The study was approved by the local ethics committee for human research in Nijmegen (Medical Review Ethics Committee Region Arnhem-Nijmegen, authorisation number: 2012/117). This study was registered on ClinicalTrials.gov (NCT02383342).

The privacy of the participants is guaranteed by storing encrypted data. Every participant will receive a pseudo-anonymous study number. No identifying data is recorded within the meaning of the law. The key is only accessible to the study team and monitors. Data and material will only be used in coded form within possible collaborations.

The results of this study will be made available through peer-reviewed scientific journals and presentations at relevant conferences. After a thorough evaluation, decisions will be made regarding including the identified risk factors and constructed prediction models into clinical guidelines, thus facilitating personalised postoperative pain management.

**DISCUSSION**

This cohort will be a large prospective study to identify risk factors for postoperative pain and to build and evaluate dedicated prediction models for postoperative pain in surgical patients. In addition, the comprehensive information collected in this study will also enable us to answer other research questions regarding postoperative pain, such as the relationships between acute and chronic postoperative pain development. Eventually, these results will be applied in the clinical settings to improve the quality of life for patients who develop postoperative pain.

The strengths of this study are that we will include all elective major operations rather than limiting to one specific operation as in previous studies, which allows us to investigate the shared genetic background of postoperative pain in different operations. Furthermore, as there are discrepancies in pain intensity scores understanding and pain management decisions between patients and caregivers, the patient’s perspective should be respected and assessed for pain evaluation and management. Therefore, pain assessment will be conducted by patients themselves (patient-reported outcomes) rather than professionals in this study, leading to a more comprehensive outcome assessment and interpretation. Moreover, the single-use of NRS might be inadequate for patients’ pain experience evaluation and pain management decisions. Thus, another strength of this cohort is that the experience of pain will be estimated by multidimensional measurements focusing on patients’ overall functionality rather than merely an NRS pain score. In addition, the comprehensively collected information for postoperative pain in this cohort also empowers analysis that cannot be performed in large-scale registry data (eg, UK Biobank) as such phenotype data are not available in those datasets. The data collected in this cohort will also enable additional research using conventional and cutting-edge statistical methods like artificial intelligence.

The possible limitations of this study are that we will only investigate DNA variants as biomarkers for pain prediction as our primary research goal. However, other epigenetic, transcriptomic, proteomic and metabolic markers are also potentially involved in (postoperative) pain development. For instance, recent studies indicate that methylation patterns might predict opioid treatment outcomes. As the DNA sample of patients is accessible, we will be able to characterise the multimics biomarker signatures of postoperative pain in future researches, such as investigating the association between epigenetic changes and postoperative pain. In addition, when prediction tools are applied in clinical settings, the sensitivity and specificity of prediction tools are crucial to evaluate their adequacy and usefulness. Although the measurement tools used in prediction models are well-validated and verified (see methods), our findings could still be subject to false positive or negative errors because all measurement tools have limitations. Furthermore, chronic pain assessment is more complex than acute pain, and GWAS findings are sometimes incidental.
We will consider seeking other available cohorts for validation and applying other statistical methods to validate our findings in future studies, such as polygenic risk scores. Another potential limitation is that loss of follow-up of patients might result in lower patient numbers than expected. Despite this potential concern, we still expect a sufficient sample size as additional centres will start patient inclusion, and the measurements are mainly from patient-reported outcomes via digital follow-up.

Identifying the genetic background of postoperative pain development may give valuable insights into the mechanisms underlying the relationship between postoperative pain and complications after surgery. This may open the way to identify new targets for treatment and potentially simplify the risk profiling assay for future use, yielding a simpler, more accurate and cost-efficient assay or product. The contribution of improved prevention and treatment of pain after surgery will benefit many patients undergoing surgery and society by decreasing healthcare service costs.

**Trial status**

Patient recruitment is expected to continue until 2025. Recruitment has already started in Radboud university medical centre, with more than 500 patients recruited as of October 2021. National and international collaborations will be greatly accepted after careful consideration.

Appendix c: Physical activities

Physical activities

Circle the one number below that best describes how much, since your surgery, pain interfered with or prevented you from doing physical activities, expressed by figure. The score means a figure between 0 and 10, where 0 means no interference and 10 means complete interference.

1. How much has pain interfered with or prevented you from doing activities in bed such as turning, sitting up, changing position (0= did not interfere, 10= completely interfered)
   0-1-2-3-4-5-6-7-8-9-10

2. How much has pain interfered with or prevented you from breathing deeply of coughing (0= did not interfere, 10= completely interfered)
   0-1-2-3-4-5-6-7-8-9-10

3. How much has pain interfered with or prevented you from sleeping (0= did not interfere, 10= completely interfered)
   0-1-2-3-4-5-6-7-8-9-10

4. Have you been out of bed since your surgery?
   Yes/no

5. If yes, how much did pain interfere or prevent you from doing activities out of bed such as walking, sitting in a chair, standing at the sink (0= did not interfere, 10= completely interfered)
   0-1-2-3-4-5-6-7-8-9-10
Appendix d: Pain disability index

Pain disability index

We would like to know how much pain is preventing you from doing what you would normally do or from doing it as well as you normally would. Respond to each category indicating the overall impact of pain in your life, not just when pain is at its worst.

For each of the 7 categories of life activity listed, please circle the number on the scale that describes the level of disability you typically experience. A score of 0 means no disability at all, and a score of 10 signifies that all of the activities in which you would normally be involved have been totally disrupted or prevented by your pain.

In case of no pain, please circle “0”.

Appendix f: Pain Catastrophizing Scale (PCS)

Pain Catastrophizing Scale (PCS)

We are interested in the types of thoughts and feelings that you have when you are in pain. Listed below are thirteen statements describing different thoughts and feelings that may be associated with pain. Using the following scale, please indicate the degree to which you have these thoughts and feelings when you are experiencing pain.

0 = not at all  1 = to a slight degree  2 = to a moderate degree  3 = to a great degree  4 = all the time

When I’m in pain ………

1. I worry all the time about whether the pain will end  0 1 2 3 4
2. I feel I can’t go on  0 1 2 3 4
3. It’s terrible and I think that it’s never going to get any better  0 1 2 3 4
4. It’s awful and I feel that it overwhelms me  0 1 2 3 4
5. I feel that I can’t stand it any more  0 1 2 3 4
6. I become afraid that the pain will get worse  0 1 2 3 4
7. I keep thinking of other painful events  0 1 2 3 4
8. I anxiously want the pain to go away  0 1 2 3 4
9. I can’t seem to keep it out of my mind  0 1 2 3 4
10. I keep thinking about how much it hurts  0 1 2 3 4
11. I keep thinking about how badly I want the pain to stop  0 1 2 3 4
12. There’s nothing I can do to reduce the intensity of the pain  0 1 2 3 4
13. I wonder whether something serious may happen  0 1 2 3 4
Appendix g: Pain Sensitivity Questionnaire

Pain Sensitivity Questionnaire

This questionnaire contains a series of questions in which you should imagine yourself in certain situations. You should then decide if these situations would be painful for you and if yes, how painful they would be.

Let 0 stand for no pain; 1 is an only just noticeable pain and 10 the most severe pain that you can imagine or consider possible.

Please mark the scale with a cross on the number that is most true for you. Keep in mind that there are no “right” or “wrong” answers; only your personal assessment of the situation counts. Please try as much as possible not to allow your fear or aversion of the imagined situations affect your assessment of painfulness.

1. Imagine you bump your shin badly on a hard edge, for example, on the edge of a glass coffee table. How painful would that be for you?
   0 = not at all painful, 10= most severe pain imaginable

   0------1-------2-------3-------4-------5-------6-------7-------8-------9-------10

2. Imagine you burn your tongue on a very hot drink.

   0------1-------2-------3-------4-------5-------6-------7-------8-------9-------10

3. Imagine your muscles are slightly sore as the result of physical activity.

   0------1-------2-------3-------4-------5-------6-------7-------8-------9-------10

4. Imagine you trap your finger in a drawer.

   0------1-------2-------3-------4-------5-------6-------7-------8-------9-------10

5. Imagine you take a shower with lukewarm water.

   0------1-------2-------3-------4-------5-------6-------7-------8-------9-------10

6. Imagine you have mild sunburn on your shoulders.
7. Imagine you grazed your knee falling off your bicycle.

8. Imagine you accidentally bite your tongue or cheek badly while eating.

9. Imagine walking across a cool tiled floor with bare feet.

10. Imagine you have a minor cut on your finger and inadvertently get lemon juice in the wound.

11. Imagine you prick your fingertip on the thorn of a rose.

12. Imagine you stick your bare hands in the snow for a couple of minutes or bring your hands in contact with snow for some time, for example, while making snowballs.

13. Imagine you shake hands with someone who has a normal grip.

14. Imagine you shake hands with someone who has a very strong grip.

15. Imagine you pick up a hot pot by inadvertently grabbing its equally hot handles.

16. Imagine you are wearing sandals and someone with heavy boots steps on your foot.
17. Imagine you bump your elbow on the edge of a table ("funny bone").

```
Appendix h: Chronic pain

Chronic pain

Did you experience any pain in the last month that lasted for a day or more?

☐ Yes, next question

☐ No

Can you indicate in the drawings below where you suffer (have suffered) from pain?

Right side  back  front  Left side

Is this the same spot as the spot you are operated on? Yes/no

Does the pain differ from the pain before surgery? Yes/no

How long have you been affected by the above-mentioned pain?

☐ Less than three months

☐ More than three months
Appendix i: Inventory of depressive symptomatology (self-report) (IDS-SR)

INVENTORY OF DEPRESSIVE SYMPTOMATOLOGY (SELF-REPORT) (IDS-SR)

NAME: ___________________  TODAY’S DATE ________________

Please circle the one response to each item that best describes you for the past seven days.

1. Falling Asleep:
   0. I never take longer than 30 minutes to fall asleep.
   1. I take at least 30 minutes to fall asleep, less than half the time.
   2. I take at least 30 minutes to fall asleep, more than half the time.
   3. I take more than 60 minutes to fall asleep, more than half the time.

2. Sleep During the Night:
   0. I do not wake up at night.
   1. I have a restless, light sleep with a few brief awakenings each night.
   2. I wake up at least once a night, but I go back to sleep easily.
   3. I awaken more than once a night and stay awake for 20 minutes or more, more than half the time.

3. Waking Up Too Early:
   0. Most of the time, I awaken no more than 20 minutes before I need to get up.
   1. More than half the time, I awaken more than 30 minutes before I need to get up.
   2. I almost always awaken at least one hour or so before I need to, but I go back to sleep eventually.
   3. I awaken at least one hour before I need to, and can’t go back to sleep.

4. Sleeping Too Much:
   0. I sleep no longer than 7-9 hours/night without napping during the day.
   1. I sleep no longer than 10 hours in a 24-hour period including naps.
   2. I sleep no longer than 12 hours in a 24-hour period including naps.
   3. I sleep longer than 12 hours in a 24-hour period including naps.

5. Feeling Sad:
   0. I do not feel sad.
   1. I feel sad less than half the time.
   2. I feel sad more than half the time.
   3. I feel sad nearly all of the time.

6. Feeling Irritable:
   0. I do not feel irritable.
   1. I feel irritable less than half the time.
   2. I feel irritable more than half the time.
   3. I feel extremely irritable nearly all of the time.

7. Feeling Anxious or Tense:
   0. I do not feel anxious or tense.
   1. I feel anxious (tense) less than half the time.
   2. I feel anxious (tense) more than half the time.
   3. I feel extremely anxious (tense) nearly all of the time.

8. Response of Your Mood to Good or Desired Events:
   0. My mood brightens to a normal level which lasts for several hours when good events occur.
   1. My mood brightens but I do not feel like my normal self when good events occur.
   2. My mood brightens only somewhat to a rather limited range of desired events.
   3. My mood does not brighten at all, even when very good or desired events occur in my life.

9. Mood in Relation to the Time of Day:
   0. There is no regular relationship between my mood and the time of day.
   1. My mood often relates to the time of day because of environmental events (e.g., being alone, working).
   2. In general, my mood is more related to the time of day than to environmental events.
   3. My mood is clearly and predictably better or worse at a particular time each day.

9A. Is your mood typically worse in the morning, afternoon or night? (circle one)

9B. Is your mood variation attributed to the environment? yes or no (circle one)

10. The Quality of Your Mood:
    0. The mood (internal feelings) that I experience is very much a normal mood.
    1. My mood is sad, but this sadness is pretty much like the sad mood I would feel if someone close to me died or left.
    2. My mood is sad, but this sadness has a rather different quality to it than the sadness I would feel if someone close to me died or left.
    3. My mood is sad, but this sadness is different from the type of sadness associated with grief or loss.

13
Please complete either 11 or 12 (not both)

11. Decreased Appetite:
0 There is no change in my usual appetite.
1 I eat somewhat less often or lesser amounts of food than usual.
2 I eat much less than usual and only with personal effort.
3 I rarely eat within a 24-hour period, and only with extreme personal effort or when others persuade me to eat.

12. Increased Appetite:
0 There is no change from my usual appetite.
1 I feel a need to eat more frequently than usual.
2 I regularly eat more often and/or greater amounts of food than usual.
3 I feel driven to overeat both at mealtime and between meals.

Please complete either 13 or 14 (not both)

13. Decreased Weight (Within the Last Two Weeks):
0 I have not had a change in my weight.
1 I feel as if I’ve had a slight weight loss.
2 I have lost 2 pounds or more.
3 I have lost 5 pounds or more.

14. Increased Weight (Within the Last Two Weeks):
0 I have not had a change in my weight.
1 I feel as if I’ve had a slight weight gain.
2 I have gained 2 pounds or more.
3 I have gained 5 pounds or more.

15. Concentration/Decision Making:
0 There is no change in my usual capacity to concentrate or make decisions.
1 I occasionally feel indecisive or find that my attention wanders.
2 Most of the time, I struggle to focus my attention or to make decisions.
3 I cannot concentrate well enough to read or cannot make even minor decisions.

16. View of Myself:
0 I see myself as equally worthwhile and deserving as other people.
1 I am more satisfying than usual.
2 I largely believe that I cause problems for others.
3 I think almost constantly about major and minor defects in myself.

17. View of My Future:
0 I have an optimistic view of my future.
1 I am occasionally pessimistic about my future, but for the most part I believe things will get better.
2 I’m pretty certain that my immediate future (1-2 months) does not hold much promise of good things for me.
3 I see no hope of anything good happening to me anytime in the future.

18. Thoughts of Death or Suicide:
0 I do not think of suicide or death.
1 I feel that life is empty or wonder if it’s worth living.
2 I think of suicide or death several times a week for several minutes.
3 I think of suicide or death several times a day in some detail, or I have made specific plans for suicide or have actually tried to take my life.

19. General Interest:
0 There is no change from usual in how interested I am in other people or activities.
1 I notice that I am less interested in people or activities.
2 I find I have interest in only one or two of my formerly pursued activities.
3 I have virtually no interest in formerly pursued activities.

20. Energy Level:
0 There is no change in my usual level of energy.
1 I get tired more easily than usual.
2 I have to make a big effort to start or finish my usual daily activities (e.g., shopping, homework, cooking, or going to work).
3 I really cannot carry out most of my usual daily activities because I just don’t have the energy.

21. Capacity for Pleasure or Enjoyment (excluding sex):
0 I enjoy pleasurable activities as much as usual.
1 I do not feel my usual sense of enjoyment from pleasurable activities.
2 I rarely get a feeling of pleasure from any activity.
3 I am unable to get any pleasure or enjoyment from anything.
22. Interest in Sex (Please Rate Interest, not Activity):
   0 I’m just as interested in sex as usual.
   1 My interest in sex is somewhat less than usual or I do not get the same pleasure from sex as I used to.
   2 I have little desire for or rarely derive pleasure from sex.
   3 I have absolutely no interest in or derive no pleasure from sex.

23. Feeling slowed down:
   0 I think, speak, and move at my usual rate of speed.
   1 I find that my thinking is slowed down or my voice sounds dull or flat.
   2 It takes me several seconds to respond to most questions and I’m sure my thinking is slowed.
   3 I am often unable to respond to questions without extreme effort.

24. Feeling restless:
   0 I do not feel restless.
   1 I’m often fidgety, wriggle my hands, or need to shift how I am sitting.
   2 I have impulses to move about and am quite restless.
   3 At times, I am unable to stay seated and need to pace around.

25. Aches and pains:
   0 I don’t have any feeling of heaviness in my arms or legs and don’t have any aches or pains.
   1 Sometimes I get headaches or pains in my stomach, back or joints but these pains are only sometime present and they don’t stop me from doing what I need to do.
   2 I have some of these pains most of the time.
   3 These pains are so bad they force me to stop what I am doing.

26. Other bodily symptoms:
   0 I don’t have any of these symptoms: heart pounding feel, blurred vision, sweating, hot and cold flashes, chest pain, heart turning over in my chest, ringing in my ears, or shaking.
   1 I have some of these symptoms but they are mild and are present only sometimes.
   2 I have several of these symptoms and they bother me quite a bit.
   3 I have several of these symptoms and when they occur I have to stop doing whatever I am doing.

27. Panic/Phobic symptoms:
   0 I have no spells of panic or specific fears (phobia) such as animals or heights.
   1 I have had one or two panic attacks or fears that do not usually change my behavior or stop me from functioning.
   2 I have significant panic episodes or fears that force me to change my behavior but do not stop me from functioning.
   3 I have panic episodes at least once a week or severe fears that stop me from carrying on my daily activities.

28. Constipation/diarrhea:
   0 There is no change in my usual bowel habits.
   1 I have intermittent constipation or diarrhea which is mild.
   2 I have diarrhea or constipation most of the time but it does not interfere with my day-to-day functioning.
   3 I have constipation or diarrhea for which I take medicines or which interferes with my day-to-day activities.

29. Interpersonal Sensitivity:
   0 I have not felt easily rejected, slighted, criticized or hurt by others at all.
   1 I have occasionally felt rejected, slighted, criticized or hurt by others.
   2 I have often felt rejected, slighted, criticized or hurt by others, but these feelings have had only slight effects on my relationships or work.
   3 I have often felt rejected, slighted, criticized or hurt by others and these feelings have impaired my relationships and work.

30. Lack of Physical Energy:
   0 I have not experienced the physical sensation of feeling weighed down and without physical energy.
   1 I have occasionally experienced periods of feeling physically weighed down and without physical energy, but without a negative effect on work, school, or activity level.
   2 I feel physically weighted down (without physical energy) more than half the time.
   3 I feel physically weighted down (without physical energy) most of the time, several hours per day, several days per week.
Appendix j: Brief Pain Inventory

1) Throughout our lives, most of us have had pain from time to time (such as minor headaches, sprains, and toothaches). Have you had pain other than these everyday kinds of pain today?
   1. Yes  2. No

2) On the diagram, shade in the areas where you feel pain. Put an X on the area that hurts the most.

3) Please rate your pain by circling the one number that best describes your pain at its worst in the past 24 hours.

   0 1 2 3 4 5 6 7 8 9 10
   No pain Pain as bad as you can imagine

4) Please rate your pain by circling the one number that best describes your pain at its least in the past 24 hours.

   0 1 2 3 4 5 6 7 8 9 10
   No pain Pain as bad as you can imagine

5) Please rate your pain by circling the one number that best describes your pain on average.

   0 1 2 3 4 5 6 7 8 9 10
   No pain Pain as bad as you can imagine

6) Please rate your pain by circling the one number that tells how much pain you have right now.

   0 1 2 3 4 5 6 7 8 9 10
   No pain Pain as bad as you can imagine

7) What treatments or medications are you receiving for your pain?

8) In the past 24 hours, how much relief have pain treatments or medications provided? Please circle the one percentage that most shows how much relief you have received.

   0% 10 20 30 40 50 60 70 80 90 100%
   No relief Complete relief

9) Circle the one number that describes how, during the past 24 hours, pain has interfered with your:

   A. General activity
   B. Mood
   C. Walking ability
   D. Normal work (includes both work outside the home and housework)
   E. Relations with other people
   F. Sleep
   G. Enjoyment of life
