Abstract

Objective: Determine if oestrogen augmentation decreases the risk of death following COVID-19.

Design: Nationwide registry-based study

Participants: Postmenopausal women between 50 and 80 years of age with verified COVID-19 were divided into three groups: 1) Women with previously diagnosed breast cancer and receiving endocrine therapy (decreased systemic oestrogen levels); 2) women receiving hormone replacement therapy (HRT; increased systemic oestrogen levels) and 3) control group not fulfilling requirements for group 1 or 2 (postmenopausal oestrogen levels).

Main outcome measures: The main outcome was death following COVID-19, and the exposure was pharmaceutical modulation of oestrogen levels. Adjustments were made for potential confounders such as age, annual disposable income (richest group as the reference category), highest level of education (primary, secondary and tertiary (reference)) and the weighted Charlson Comorbidity Index (wCCI).

Results: From a nationwide cohort consisting of 49,853 women diagnosed with COVID-19 between the 4th of February to 14th of September 2020 in Sweden, 16,693 were between 50 to 80 years of age. We included 14,685 women in the study with 11,923 (81%) in the control group, 227 (2%) women in group 1 and 2,535 (17%) women in group 2. The unadjusted odds ratio (OR) for death following COVID-19 was 2.35 (95% CI 1.51-3.65) for group 1 and 0.45 (0.34-0.6) for group 2. Only the adjusted OR for death remained significant for group 2 with OR 0.47 (0.34-0.63). The risk of death due to COVID-19 was significantly associated with: Age OR 1.15 (1.14-1.17); annual income (poorest 2.79 (1.96-3.97); poor 2.43 (1.71-3.46) and middle 1.64 (1.11-2.41)); education (primary 1.4 (1.07-1.81)) and wCCI 1.13 (1.1-1.16).
Conclusions: Oestrogen supplementation in post-menopausal women is associated with a decreased risk of dying from COVID-19 in this nationwide cohort study. These findings are limited by the retrospective and non-randomized design. Further randomized intervention trials are warranted.
Strengths and limitations of the study

- This study is based on all diagnosed COVID-19 patients in Sweden
- Swedish registry data is well-validated and due to historical registry data and cross-linkage with the registries of Statistics Sweden, the confounding and/or effect modifying effects of socioeconomic variables and comorbidities could be adjusted for
- It investigates the effect of pharmaceutical modulation of oestrogen in post-menopausal women on death due to COVID-19
- The findings are limited by the retrospective and non-randomized design.
Introduction

The coronavirus disease 2019 (COVID-19) pandemic has swept across the globe causing enormous strain on societies and health care systems. Although women are infected, they appear to be protected from poor outcome when compared to men even after adjustment for confounding risk factors\(^1\)\(^2\). Similar epidemiological findings have also been described for SARS-CoV and MERS-CoV infections\(^3\)\(^4\)\(^5\). This implies biological differences between the sexes in terms of sensitivity to severe COVID-19, and oestrogen has been identified as a potential therapeutic candidate.

The majority of breast cancer (BC) patients have oestrogen receptor (ER) positive cancer\(^6\), and are usually given adjuvant endocrine therapy after surgery in order to reduce the risk of cancer recurrences, leading to reduced systemic oestrogen levels. On the other hand, systemic oestrogen levels are augmented in women taking hormone replacement therapy (HRT) for relieving menopausal symptoms\(^7\). We use the opposing effects of endocrine therapy in BC patients and HRT in modulating systemic oestrogen levels in postmenopausal women as a model to test the hypothesis whether increased oestrogen levels are protective towards COVID-19 death in a nationwide cohort.
77 Materials and methods

78 Patients and public involvement statement

79 All data from the Swedish registries were pseudonoymized and therefore patients were not involved in the study.

82 Participants and sources of data

83 The personal identification numbers (PINs) from all diagnosed COVID-19 individuals in Sweden (SmiNet) between the 1st of February to 14th of September 2020 were cross-linked with the LISA Register (Longitudinal integrated database for health insurance and labor marker studies) administered by Statistics Sweden; and the following healthcare registers administered by the Swedish National Board of Health and Welfare: Patient; Cancer; Prescribed pharmaceutical and Causes of Death. Post-menopausal women between the ages of 50-80 years of age were stratified into three groups: Oestrogen decrease (group 1): BC as identified by international classification of diseases (ICD) version 10 code C50, and the following treatment: tamoxifen or fulvestrant (anatomical therapeutic chemical (ATC): L02BA01, L02BA03) or an aromatase inhibitor (AI; ATC L02BG03, L02BG04, and L02BG06). Augmented oestrogen (group 2): Drugs classified as HRT (ATC codes: G03CA03, G03CA04, G03CC07, G03CX01, G03FA, G03FB). All ATC codes for group 1 and 2 were identified from the Prescribed Pharmaceutical Register with at least two consecutive withdrawals and at least one time should be during the period 2019-07-01 - to the latest date. Native oestrogen (control group): No BC diagnosis, and no prescription of the above-mentioned pharmaceuticals at any time point during 2019 and 2020. Ethical permit was granted by the Swedish Ethical Review Authority.

100 Outcome, confounders and effect modifiers

101 The outcome was death due to COVID-19 as identified by the ICD-10 code U07 as the main or contributing cause of death from the Cause of Death Register. Potential confounders and effect modifiers were included in the model and consisted of the weighted Charlson comorbidity index (wCCI)\(^8\), age at COVID-19 diagnosis, income (divided into quintiles with the richest group as the
reference) and education (primary, secondary and tertiary (=reference)). The wCCI was calculated using the Patient and Cancer Registers, and up to two months prior to the COVID-19 date in order not to include complications due to COVID-19 as a comorbidity. If there was no information regarding diagnosis codes required for wCCI scoring, the individual was assigned a wCCI of zero. Information regarding income and education was retrieved from the LISA-register.

Statistical methods

The distribution of continuous and categorical variables in the three groups was tested using ANOVA and the χ² test, respectively. Each variable was then analyzed with univariate logistic regression models, followed by a multivariable regression model to compare the control group with group 1 and 2, respectively, and adjusting for confounders. Descriptive analyses and logistic regression models were performed in R statistical software version 4.0.2 using finalfit package 1.0.2.
Results

Participants

During the study period a total of 49,853 women of all ages were diagnosed with COVID-19 in Sweden, and a total of 14,685 women between the ages of 50-80 years of age were included in our study (Figure 1). Characteristics of these groups are shown in Table 1. Individuals with decreased oestrogen due to adjuvant endocrine therapy for BC (group 1) were older with a higher comorbidity index. A larger proportion of women in group 2 (increased levels of systemic oestrogen due to HRT) had high income and tertiary level of education (Table 1).

Oestrogen augmentation protects against death due to COVID-19

Pharmaceutically decreasing systemic oestrogen levels increased the odds of dying due to COVID-19 (group 1; odds ratio (OR) 2.35 95% confidence intervals (CI) 1.51-3.65), but following adjustment for confounders this association was no longer significant (Figure 2). Interestingly, augmentation of systemic oestrogen levels decreased the odds of dying due to COVID-19 with OR 0.45 (95% CI: 0.34-0.6), which remained significant even after adjustment for confounders (0.47 (95% CI: 0.34-0.63)). As expected, higher age and wCCI increased the odds of dying due to COVID-19. For every year increase in age the odds of dying was 1.15 (95% CI: 1.14-1.17) and for every increase in wCCI the odds of dying was 1.13 (95% CI: 1.10-1.16) (Figure 2). Furthermore, low income and having only primary level education were also factors that increased the odds of dying due to COVID-19 (Figure 2).
Discussion

Principal findings

The major finding of this nationwide registry-based study is that pharmaceutically augmenting oestrogen levels is associated with decreased odds of death due to COVID-19.

Comparison with related studies

There are several possible biological explanations for the lower risk experienced by women. These include mechanisms directly involved in viral internalization and reproduction, where oestrogen has been shown to decrease expression of vital proteins such as ACE2 and TMPRSS2, inherent sex-linked differences in the immune system and direct oestrogen effects. Our findings are supported by in vitro studies where 17β-estradiol treatment reduced viral load of SARS-CoV-2. Previous experimental studies in mice on SARS-CoV have moreover shown that female mice were less susceptible to infection, and that this protection was lost upon oophorectomy thus indicating a direct protective role of oestrogen signalling. Furthermore, Barh et al. showed using a multiomics approach on SARS-CoV-2 infected host interactome, proteome, transcriptome, and bibliome datasets that oestrogen modulation could be a potential therapeutic option in COVID-19. Our findings are further verified by a smaller study of women taking HRT (n=439) that showed similar results with oestrogen augmentation being associated lower risk of COVID-19 death, although in that study the risk selection bias was more difficult to discern since the cohort was neither population-based nor adjusted for central confounders. In our study the effect of increased systemic oestrogen levels on reducing the risk of COVID-19 death remained significant also after adjusting for education level and income, both factors known to influence COVID-19 outcome, which further supports the protective role of oestrogen in women.

The hypothetic inverse, worsening, effect of reduced systemic oestrogen levels in women with a previous BC receiving adjuvant endocrine therapy was initially significant but not after adjusting for confounders. This population differs from the control group in that they all have been diagnosed with BC and it has been shown that patients, both men and women, with any cancer form are harder hit by COVID-19. However, BC patients were in a previous study shown to be healthier compared to the
background population in terms of ischemic cardiac disease and CCI, and the wCCI adjustments may therefore overcompensate for this cancer-related vulnerability. Although not significant, a trend towards worse outcome remained and thus a larger population of BC patients on endocrine therapy is likely needed to verify the finding. Thus, this study cannot exclude an increased risk for death from COVID-19 if systemic oestrogen levels are pharmaceutically decreased.

Strengths and limitations

Strengths of this study are that this is a nationwide cohort in a country with high COVID-19 incidence using well validated registry data. A weakness is that the level of oestrogen modulation cannot be exactly measured in each individual, and that the number of BC women on anti-oestrogen medication ended up being too small to show significance although there was a clear trend. The HRT group, however, proved large enough to show the clear protective effect.

Implications and conclusion

The present study shows an association between oestrogen levels and COVID-19 death. Consequently, drugs increasing oestrogen levels may have a role in therapeutic efforts to alleviate COVID-19 severity in post-menopausal women and could be studied in randomized control trials.

Contributors

MS and KW conceptualized the study. MS and AMFC designed the study. OFR and AMFC prepared the study data. OFR performed the statistical analysis. All authors contributed to interpretation of the results. MS wrote the first draft of the manuscript. All authors contributed to critical revision of the manuscript. All authors approved the final manuscript. AMFC is the guarantor of this study. The corresponding author attests that all authors meet the criteria for authorship and that all have been included.

Competing interests

All authors have completed the ICMJE uniform disclosure form at www.icmje.org/coi_disclosure.pdf and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous three years; no other relationships or activities that could appear to have influenced the submitted work.

Ethical approval

Ethical approval was obtained by the Swedish Ethical Review Authority (number 2020-02150)
Data sharing

The study protocol (R script) is available upon request. The study used secondary registry data which is regulated by the Public Access to Information and Secrecy Act (2009:400) and is protected by strict confidentiality. For the purpose of research though, after formal application to access personal data, the responsible authority can grant access to data, though this is contingent on vetting by the Ethical Review Authority of Sweden, according to the Act (2003:460) concerning the Ethical Review of Research Involving Humans. This means that the aggregated registry data cannot be shared.

Continued on next page
Results

Participants 13*
(a) Report numbers of individuals at each stage of study—e.g., numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed
(b) Give reasons for non-participation at each stage
(c) Consider use of a flow diagram

Descriptive data 14*
(a) Give characteristics of study participants (e.g., demographic, clinical, social) and information on exposures and potential confounders
(b) Indicate number of participants with missing data for each variable of interest
(c) Cohort study—Summarise follow-up time (e.g., average and total amount)

Outcome data 15*
Cohort study—Report numbers of outcome events or summary measures over time
Case-control study—Report numbers in each exposure category, or summary measures of exposure
Cross-sectional study—Report numbers of outcome events or summary measures

Main results 16
(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (e.g., 95% confidence interval). Make clear which confounders were adjusted for and why they were included
(b) Report category boundaries when continuous variables were categorized
(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period

Other analyses 17
Report other analyses done—e.g., analyses of subgroups and interactions, and sensitivity analyses

Discussion

Key results 18
Summarise key results with reference to study objectives

Limitations 19
Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias

Interpretation 20
Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence

Generalisability 21
Discuss the generalisability (external validity) of the study results

Other information

Funding 22
Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Association between pharmaceutical modulation of oestrogen in postmenopausal women in Sweden with death due to COVID-19 – a cohort study

Abstract

Objective: Determine whether augmentation of oestrogen in post-menopausal women decreases the risk of death following COVID-19.

Design: Nationwide study in Sweden based on registries from The Swedish Public Health Agency; Statistics Sweden (socioeconomical variables) and the National Board of Health and Welfare (Causes of death).

Participants: Postmenopausal women between 50 and 80 years of age with verified COVID-19.

Interventions: Pharmaceutical modulation of oestrogen as defined by (1) women with breast cancer receiving endocrine therapy (decreased systemic oestrogen levels); (2) postmenopausal hormone therapy (HT; increased systemic oestrogen levels) and (3) a control group (postmenopausal oestrogen levels). Adjustments were made for potential confounders such as age, annual disposable income (richest group as the reference category), highest level of education (primary, secondary and tertiary (reference)) and the weighted Charlson Comorbidity Index (wCCI).

Primary outcome measure: Death following COVID-19.

Results: From a nationwide cohort consisting of 49,853 women diagnosed with COVID-19 between February 4 and September 14, 2020 in Sweden, we included 14,685 women in the study with 11,923 (81%) in the control group, 227 (2%) women in group 1 and 2,535 (17%) women in group 2. The unadjusted odds ratio (OR) for death following COVID-19 was 2.35
(95% CI 1.51-3.65) for group 1 and 0.45 (0.34-0.6) for group 2. Only the adjusted OR for death remained significant for group 2 with OR 0.47 (0.34-0.63). Absolute risk (AR) of death was 4.6% for the control group vs 10.1% and 2.1%, for the decreased and increased oestrogen groups, respectively. The risk of death due to COVID-19 was significantly associated with: age, annual income, and education.

Conclusions: Oestrogen supplementation in post-menopausal women is associated with a decreased risk of dying from COVID-19 in this nationwide cohort study. These findings are limited by the retrospective and non-randomized design. Further randomized intervention trials are warranted.

Strengths and limitations of the study

- This study is based on all diagnosed COVID-19 patients in Sweden between February 1 and September 14, 2020
- Swedish registry data is well-validated and due to historical registry data and cross-linkage with the registries of Statistics Sweden, the confounding and/or effect-modifying effects of socioeconomic variables and comorbidities could be adjusted for
- The findings are limited by the retrospective and non-randomized design.
- Information regarding compliance to pharmaceutical modulation of oestrogen is missing
- Circulating oestrogen levels are not measured
Introduction

The coronavirus disease 2019 (COVID-19) pandemic has swept across the globe causing enormous strain on societies and health care systems. Although women are infected, they appear to be protected from poor outcomes when compared with men even after adjustment for confounding risk factors\(^1\)\(^2\). Similar epidemiological findings have also been described for SARS-CoV and MERS-CoV infections\(^3\)\(^4\)\(^5\). This implies biological differences between the sexes in terms of sensitivity to severe COVID-19, and oestrogen has been identified as a potential therapeutic candidate.

The majority of breast cancer (BC) patients have oestrogen receptor (ER)-positive cancer\(^6\) and are usually given adjuvant endocrine therapy after surgery in order to reduce the risk of cancer recurrences, leading to reduced systemic oestrogen levels. On the other hand, systemic oestrogen levels are augmented in women taking postmenopausal hormone therapy (HT) to relieve menopausal symptoms\(^7\). In a nationwide cohort, we used the opposing effects of endocrine therapy in BC patients and women taking postmenopausal HT in modulating systemic oestrogen levels as a model to test the hypothesis that increased oestrogen levels are protective towards COVID-19 death.
Materials and methods

Patients and public involvement statement

All data from the Swedish registries were pseudonymised and therefore patients were not involved in the study.

Participants and sources of data

The personal identification numbers (PINs) from all diagnosed COVID-19 individuals in Sweden (SmiNet) between the February 1 and September 14, 2020 were cross-linked with the LISA Register (Longitudinal integrated database for health insurance and labour market studies) administered by Statistics Sweden; and the following healthcare registers administered by the Swedish National Board of Health and Welfare: patient, cancer, prescribed pharmaceutical, and causes of death. Post-menopausal women 50-80 years of age were stratified into three groups as follows: Group 1, the decreased oestrogen group, included patients with BC as identified by the International Classification of Diseases (ICD) version 10 code C50, and the following treatments: tamoxifen or fulvestrant (anatomical therapeutic chemical (ATC): L02BA01, L02BA03) or an aromatase inhibitor (AI; ATC L02BG03, L02BG04, and L02BG06). Group 2, the augmented oestrogen group, included those patients treated with drugs classified as postmenopausal hormone therapy (ATC codes G03CA03, G03CA04, G03CC07, G03CX01, G03FA, and G03FB). All ATC codes for groups 1 and 2 were identified from the Prescribed Pharmaceutical Register with at least two consecutive withdrawals and at least one during the period extending from July 1, 2019 - to the latest date. Group 3, the native oestrogen (control) group, included patients with no BC diagnosis and no prescription of the above-mentioned pharmaceuticals at any time during 2019 and 2020. Ethical approval was granted by the Swedish Ethical Review Authority.
Outcome, confounders and effect modifiers

The outcome was death due to COVID-19, as identified by the ICD-10 code U07, as the main or contributing cause of death from the Cause of Death Register. Potential confounders and effect modifiers were included in the model and consisted of the weighted Charlson comorbidity index (wCCI), age at COVID-19 diagnosis, income (divided into quintiles with the richest group as the reference) and education (primary, secondary and tertiary, which served as the reference). The wCCI was calculated using the Patient and Cancer Registers, up to 2 months prior to the COVID-19 date in order not to include complications due to COVID-19 as a comorbidity. If there was no information regarding diagnosis codes required for wCCI scoring, the individual was assigned a wCCI of zero. Information regarding income and education was retrieved from the LISA-register.

Statistical methods

The distributions of continuous and categorical variables in the three groups were tested using ANOVA and the \( \chi^2 \) test, respectively. Each variable was then analysed with univariate logistic regression models, followed by a multivariable regression model to compare the control group with groups 1 and 2, respectively, and adjusting for confounders. Descriptive analyses and logistic regression models were performed using R statistical software version 4.0.2, using the finalfit package 1.0.2.
Results

Participants

During the study period a total of 49,853 women of all ages were diagnosed with COVID-19 in Sweden, and a total of 14,685 women aged 50-80 years were included in our study (figure 1). Characteristics of these groups are shown in table 1. Individuals with decreased oestrogen due to adjuvant endocrine therapy for BC (group 1) were older with a higher comorbidity index. A larger proportion of women in group 2 (increased levels of systemic oestrogen due to postmenopausal HT) had high income and a tertiary level of education (table 1).

Oestrogen augmentation protects against death due to COVID-19

Pharmaceutically decreasing systemic oestrogen levels increased the odds of dying due to COVID-19 (group 1: odds ratio [OR] 2.35, 95% confidence intervals [CI] 1.51 - 3.65), but following adjustment for confounders this association was no longer significant (figure 2). Interestingly, augmentation of systemic oestrogen levels decreased the odds of dying due to COVID-19, with OR 0.45 (95% CI 0.34 - 0.6), and this result remained significant even after adjustment for confounders (OR 0.47, 95% CI 0.34 - 0.63). The absolute risk (AR) of dying was 4.6% for the control group vs. 10.1% and 2.1% for the groups with decreased and increased oestrogen, respectively.

As expected, higher age and wCCI increased the odds of dying due to COVID-19. For every year increase in age the odds of dying were 1.15 (95% CI 1.14-1.17), and for every increase in wCCI the odds of dying were 1.13 (95% CI 1.10-1.16) (figure 2). Furthermore, low income and having only primary education were also factors that increased the odds of dying due to COVID-19 (figure 2).
Discussion

Principal findings
The major finding of this nationwide registry-based study is that pharmaceutical augmentation of oestrogen levels is associated with decreased odds of death due to COVID-19 in postmenopausal women.

Comparison with related studies
There are several possible biological explanations for the lower risk experienced by women. These include mechanisms directly involved in viral internalization and reproduction, where oestrogen has been shown to decrease expression of vital proteins such as ACE2 and TMPRSS2, inherent sex-linked differences in the immune system, and direct oestrogen effects. As an example, Kalidhindi et al have studied the effect of testosterone and oestrogen on ACE2 expression, a key cell entry for SARS-CoV-2 virus, using in vitro experiments on isolated human airway smooth muscle cells of male and female origin. Most interestingly, they show that cells exposed to oestrogen and testosterone behave differently, as testosterone significantly upregulates ACE2 expression in cells from both sexes, whereas oestrogen downregulates ACE2. ACE2 expression and differences in its expression in relation to sex could also be linked to the higher mortality in relation to hypertension, venous thromboembolism and SARS-CoV-2 infection between men and women. The observed oestrogen induced reduction of ACE2 expression might however not necessarily translate into a reduction of ACE2 protein at the cell surface in vivo in all cell types. Our findings are also supported by in vitro studies where 17β-oestradiol treatment reduced SARS-CoV-2 viral load. Previous experimental studies in mice on SARS-CoV have, moreover, shown that female mice are less susceptible to infection and that this protection was lost upon oophorectomy, thus indicating a direct protective role of oestrogen signalling. Furthermore,
Barh et al., using a multiomics approach on SARS-CoV-2-infected host interactome, proteome, transcriptome, and bibliome datasets, demonstrated that oestrogen modulation could be a potential therapeutic option in COVID-19. Our results are in line with those by Seeland et al using real world evidence from multiple institutions and the TriNetX platform. They found by using propensity score matched analysis of data for women aged 50 and above with COVID-19 (n=439), that there was a survival benefit for oestradiol hormone-users versus non-users (OR 0.33 (95%CI 0.18-0.62)). Although based on a large real-world dataset the risk of selection bias was more difficult to discern since the cohort was neither population-based nor adjusted for central confounders although likely mitigated by the propensity score matched analysis. In our study the effect of increased systemic oestrogen levels on reducing the risk of COVID-19 death remained significant after adjusting for education level and income, both factors known to influence COVID-19 outcome, further supporting the protective role of oestrogen in women.

The hypothetical inverse, a worsening effect of reduced systemic oestrogen levels in women with a previous BC receiving adjuvant endocrine therapy, was initially significant but not after adjusting for confounders. This population differs from the control group in that they all have been diagnosed with BC and it has been shown that patients, both men and women, with any cancer are harder hit by COVID-19. However, in a previous study BC patients were shown to be healthier compared with the background population in terms of ischemic cardiac disease and CCI, and the wCCI adjustments may therefore overcompensate for this cancer-related vulnerability. Although not significant, a trend towards worse outcome remained and thus a larger population of BC patients on endocrine therapy is likely needed to verify the finding. Thus, this study cannot exclude an increased risk of death from COVID-19 if systemic oestrogen levels are pharmacetically decreased.
Strengths and limitations

The strengths of this study are that this is a nationwide cohort in a country with high COVID-19 incidence using well validated registry data. A weakness is that the level of oestrogen modulation cannot be exactly measured in each individual, and that the number of BC women on anti-oestrogen medication ended up being too small to show significance although there was a clear trend. The postmenopausal HT group, however, proved large enough to show the clear protective effect. A further limitation is that confounding factors such as body mass index (BMI), nutrition and smoking habits are not available in the nationwide registry data.

Implications and conclusion

This study shows an association between oestrogen levels and COVID-19 death. Consequently, drugs increasing oestrogen levels may have a role in therapeutic efforts to alleviate COVID-19 severity in post-menopausal women and could be studied in randomized control trials.

Abstract

Objective: Determine whether augmentation of oestrogen in post-menopausal women decreases the risk of death following COVID-19.

Design: Nationwide registry-based study in Sweden based on registries from The Swedish Public Health Agency (all individuals that tested positive for SARS-CoV-2); Statistics Sweden (socioeconomical variables) and the National Board of Health and Welfare (Causes of death).

Participants: Postmenopausal women between 50 and 80 years of age with verified COVID-19.

Interventions: Pharmaceutical modulation of oestrogen as defined by (1) women with previously diagnosed breast cancer and receiving endocrine therapy (decreased systemic oestrogen levels); (2) women receiving hormone replacement therapy (HRT; increased systemic oestrogen levels) and (3) a control group not fulfilling requirements for group 1 or 2 (postmenopausal oestrogen levels). Adjustments were made for potential confounders such as age, annual disposable income (richest group as the reference category), highest level of education (primary, secondary and tertiary (reference)) and the weighted Charlson Comorbidity Index (wCCI).

Primary outcome measure: Death following COVID-19.

Results: From a nationwide cohort consisting of 49,853 women diagnosed with COVID-19 between February 4 and September 14, 2020 in Sweden, 16,693 were between 50 to 80 years
of age. We included 14,685 women in the study with 11,923 (81%) in the control group, 227
(2%) women in group 1 and 2,535 (17%) women in group 2. The unadjusted odds ratio (OR)
for death following COVID-19 was 2.35 (95% CI 1.51-3.65) for group 1 and 0.45 (0.34-0.6)
for group 2. Only the adjusted OR for death remained significant for group 2 with OR 0.47
(0.34-0.63). Absolute risk (AR) of death was 4.6% for the control group vs 10.1% and 2.1%,
for the decreased and increased oestrogen groups, respectively. The risk of death due to
COVID-19 was significantly associated with: age, OR 1.15 (1.14-1.17); annual income,
poorest 2.79 [1.96-3.97], poor 2.43 [1.71-3.46] and middle 1.64 [1.11-2.41]; and education
(primary 1.4 [1.07-1.81]) and wCCI 1.13 [1.1-1.16].

Conclusions: Oestrogen supplementation in post-menopausal women is associated with a
decreased risk of dying from COVID-19 in this nationwide cohort study. These findings are
limited by the retrospective and non-randomized design. Further randomized intervention
trials are warranted.

Strengths and limitations of the study

- This study is based on all diagnosed COVID-19 patients in Sweden between February
  1 and September 14, 2020
- Swedish registry data is well-validated and due to historical registry data and cross-
  linkage with the registries of Statistics Sweden, the confounding and/or effect-
  modifying effects of socioeconomic variables and comorbidities could be adjusted for
- The findings are limited by the retrospective and non-randomized design.
- Information regarding compliance to pharmaceutical modulation of oestrogen is
  missing
• Information about the exact duration of the postmenopausal hormone therapy (HT) was not available in the dataset
• Circulating oestrogen levels are not measured
Introduction

The coronavirus disease 2019 (COVID-19) pandemic has swept across the globe causing enormous strain on societies and health care systems. Although women are infected, they appear to be protected from poor outcomes when compared with men even after adjustment for confounding risk factors. Similar epidemiological findings have also been described for SARS-CoV and MERS-CoV infections. This implies biological differences between the sexes in terms of sensitivity to severe COVID-19, and oestrogen has been identified as a potential therapeutic candidate.

The majority of breast cancer (BC) patients have oestrogen receptor (ER)-positive cancer and are usually given adjuvant endocrine therapy after surgery in order to reduce the risk of cancer recurrences, leading to reduced systemic oestrogen levels. On the other hand, systemic oestrogen levels are augmented in women taking postmenopausal hormone therapy (HT) to relieve menopausal symptoms. In a nationwide cohort, we used the opposing effects of endocrine therapy in BC patients and women taking postmenopausal HT in modulating systemic oestrogen levels as a model to test the hypothesis that increased oestrogen levels are protective towards COVID-19 death.
Materials and methods

Patients and public involvement statement

All data from the Swedish registries were pseudonymised and therefore patients were not involved in the study.

Participants and sources of data

The personal identification numbers (PINs) from all diagnosed COVID-19 individuals in Sweden (SmiNet) between the February 1 and September 14, 2020 were cross-linked with the LISA Register (Longitudinal integrated database for health insurance and labour market studies) administered by Statistics Sweden; and the following healthcare registers administrated by the Swedish National Board of Health and Welfare: patient, cancer, prescribed pharmaceutical, and causes of death. Post-menopausal women 50-80 years of age were stratified into three groups as follows: Group 1, the decreased oestrogen group, included patients with BC as identified by the International Classification of Diseases (ICD) version 10 code C50, and the following treatments: tamoxifen or fulvestrant (anatomical therapeutic chemical (ATC): L02BA01, L02BA03) or an aromatase inhibitor (AI; ATC L02BG03, L02BG04, and L02BG06). Group 2, the augmented oestrogen group, included those patients treated with drugs classified as postmenopausal hormone therapy (ATC codes G03CA03, G03CA04, G03CC07, G03CX01, G03FA, and G03FB). All ATC codes for groups 1 and 2 were identified from the Prescribed Pharmaceutical Register with at least two consecutive withdrawals and at least one during the period extending from July 1, 2019 - to the latest date. Group 3, the native oestrogen (control) group, included patients with no BC diagnosis and no prescription of the above-mentioned pharmaceuticals at any time during 2019 and 2020. Ethical approval was granted by the Swedish Ethical Review Authority.
Outcome, confounders and effect modifiers

The outcome was death due to COVID-19, as identified by the ICD-10 code U07, as the main or contributing cause of death from the Cause of Death Register. Potential confounders and effect modifiers were included in the model and consisted of the weighted Charlson comorbidity index (wCCI), age at COVID-19 diagnosis, income (divided into quintiles with the richest group as the reference) and education (primary, secondary and tertiary, which served as the reference). The wCCI was calculated using the Patient and Cancer Registers, up to 2 months prior to the COVID-19 date in order not to include complications due to COVID-19 as a comorbidity. If there was no information regarding diagnosis codes required for wCCI scoring, the individual was assigned a wCCI of zero. Information regarding income and education was retrieved from the LISA-register.

Statistical methods

The distributions of continuous and categorical variables in the three groups were tested using ANOVA and the $\chi^2$ test, respectively. Each variable was then analysed with univariate logistic regression models, followed by a multivariable regression model to compare the control group with groups 1 and 2, respectively, and adjusting for confounders. The present study evaluates specific outcomes, and the odds ratio and p-values are adjusted for relevant confounders using the multivariate logistic regression model and there was no need to further adjust using the Bonferroni/Benjamini/FDR approach. Descriptive analyses and logistic regression models were performed using R statistical software version 4.0.2, using the finalfit package 1.0.2.
Results

Participants

During the study period a total of 49,853 women of all ages were diagnosed with COVID-19 in Sweden, and a total of 14,685 women aged 50-80 years were included in our study (figure 1). Characteristics of these groups are shown in table 1. Individuals with decreased oestrogen due to adjuvant endocrine therapy for BC (group 1) were older with a higher comorbidity index. A larger proportion of women in group 2 (increased levels of systemic oestrogen due to postmenopausal HT) had high income and a tertiary level of education (table 1).

Oestrogen augmentation protects against death due to COVID-19

Pharmacologically decreasing systemic oestrogen levels increased the odds of dying due to COVID-19 (group 1: odds ratio [OR] 2.35, 95% confidence intervals [CI] 1.51 - 3.65), but following adjustment for confounders this association was no longer significant (figure 2). Interestingly, augmentation of systemic oestrogen levels decreased the odds of dying due to COVID-19, with OR 0.45 (95% CI 0.34 - 0.6), and this result remained significant even after adjustment for confounders (OR 0.47, 95% CI 0.34 - 0.63). The absolute risk (AR) of dying was 4.6% for the control group vs. 10.1% and 2.1% for the groups with decreased and increased oestrogen, respectively.

As expected, higher age and wCCI increased the odds of dying due to COVID-19. For every year increase in age the odds of dying were 1.15 (95% CI 1.14-1.17), and for every increase in wCCI the odds of dying were 1.13 (95% CI 1.10-1.16) (figure 2). Furthermore, low income and having only primary education were also factors that increased the odds of dying due to COVID-19 (figure 2).
Discussion

Principal findings

The major finding of this nationwide registry-based study is that pharmaceutical augmentation of oestrogen levels is associated with decreased odds of death due to COVID-19 in postmenopausal women.

Comparison with related studies

There are several possible biological explanations for the lower risk experienced by women. These include mechanisms directly involved in viral internalization and reproduction, where oestrogen has been shown to decrease expression of vital proteins such as ACE2 and TMPRSS2, inherent sex-linked differences in the immune system, and direct oestrogen effects. As an example, Kalidhindi et al have studied the effect of testosterone and oestrogen on ACE2, a key cell entry for SARS-CoV-2 virus, using in vitro experiments on isolated human airway smooth muscle cells of male and female origin. Most interestingly, they show that cells exposed to oestrogen and testosterone behave differently, as testosterone significantly upregulates ACE2 expression in cells from both sexes, whereas oestrogen downregulates ACE2. ACE2 expression and differences in its expression in relation to sex could also be linked to the higher mortality in relation to hypertension, venous thromboembolism and SARS-CoV-2 infection between men and women. Our findings are also supported by in vitro studies where 17β-oestradiol treatment reduced SARS-CoV-2 viral load. Previous experimental studies in mice on SARS-CoV have, moreover, shown that female mice are less susceptible to infection and that this protection was lost upon oophorectomy, thus indicating a direct protective role of oestrogen signalling. Furthermore, Barh et al., using a multiomics approach on SARS-CoV-2-infected host interactome, proteome, transcriptome, and bibliome datasets, demonstrated that oestrogen modulation...
could be a potential therapeutic option in COVID-19. Our results are in line with those by Seeland et al using real world evidence from multiple institutions and the TriNetX platform. They found by using propensity score matched analysis of data for women aged 50 and above with COVID-19 (n=439), that there was a survival benefit for oestradiol hormone-users versus non-users (OR 0.33 (95%CI 0.18-0.62)). Although based on a large real-world dataset the risk of selection bias was more difficult to discern since the cohort was neither population-based nor adjusted for central confounders although likely mitigated by the propensity score matched analysis. In our study the effect of increased systemic oestrogen levels on reducing the risk of COVID-19 death remained significant after adjusting for education level and income, both factors known to influence COVID-19 outcome, further supporting the protective role of oestrogen in women. Adjusting for income and education is important as we have previously shown the how these affect the risk of dying due to COVID-19 in Sweden.

The hypothetical inverse, a worsening effect of reduced systemic oestrogen levels in women with a previous BC receiving adjuvant endocrine therapy, was initially significant but not after adjusting for confounders. This population differs from the control group in that they all have been diagnosed with BC and it has been shown that patients, both men and women, with any cancer are harder hit by COVID-19. However, in a previous study BC patients were shown to be healthier compared with the background population in terms of ischemic cardiac disease and CCI, and the wCCI adjustments may therefore overcompensate for this cancer-related vulnerability. Although not significant, a trend towards worse outcome remained and thus a larger population of BC patients on endocrine therapy is likely needed to verify the finding. Thus, this study cannot exclude an increased risk of death from COVID-19 if systemic oestrogen levels are pharmaceutically decreased.
Strengths and limitations

The strengths of this study are that this is a nationwide cohort in a country with high COVID-19 incidence using well validated registry data. A weakness is that the level of oestrogen modulation cannot be exactly measured in each individual, and that the number of BC women on anti-oestrogen medication ended up being too small to show significance although there was a clear trend. Furthermore, we do not have data on the exact duration of postmenopausal HT for the individuals. The postmenopausal HT group, however, proved large enough to show the clear protective effect. A further limitation is that confounding factors such as body mass index (BMI), nutrition and smoking habits are not available in the nationwide registry data.

Implications and conclusion

This study shows an association between oestrogen levels and COVID-19 death. Consequently, drugs increasing oestrogen levels may have a role in therapeutic efforts to alleviate COVID-19 severity in post-menopausal women and could be studied in randomized control trials.

**Ethical approval**

Ethical approval was obtained by the Swedish Ethical Review Authority (number 2020-02150)

**Data sharing**

The study protocol (R script) is available upon request. The study used secondary registry data that are regulated by the Public Access to Information and Secrecy Act (2009:400) and are protected by strict confidentiality. For the purpose of research though, after formal application to access personal data the responsible authority can grant access to data, though this is contingent on vetting by the Ethical Review Authority of Sweden, according to the Act (2003:460) concerning the Ethical Review of Research Involving Humans. This means that the aggregated registry data cannot be shared.
