Barriers to healthcare and self-reported adverse outcomes for autistic adults: a cross-sectional study

Mary Doherty,1 Stuart Neilson,2 Jane O’Sullivan,3 Laura Carrawallah,4 Mona Johnson,5 Walter Cullen,6 Sebastian C K Shaw7

ABSTRACT

Objectives Autistic people experience poor physical and mental health along with reduced life expectancy compared with non-autistic people. Our aim was to identify self-reported barriers to primary care access by autistic adults compared with non-autistic adults and to link these barriers to self-reported adverse health consequences.

Design Following consultation with the autistic community at an autistic conference, Autoscape, we developed a self-report survey, which we administered online through social media platforms.

Setting A 52-item, international, online survey.

Participants 507 autistic adults and 157 non-autistic adults.

Primary and secondary outcome measures Self-reported barriers to accessing healthcare and associated adverse health outcomes.

Results Eighty per cent of autistic adults and 37% of non-autistic respondents reported difficulty visiting a general practitioner (GP). The highest-rated barriers by autistic adults were deciding if symptoms warrant a GP visit (72%), difficulty making appointments by telephone (62%), not feeling understood (56%), difficulty communicating with their doctor (53%) and the waiting room environment (51%). Autistic adults reported a preference for online or text-based appointment booking, facility to email in advance the reason for consultation, the first or last clinic appointment and a quiet place to wait. Self-reported adverse health outcomes experienced by autistic adults were associated with barriers to accessing healthcare. Adverse outcomes included untreated physical and mental health conditions, not attending specialist referral or screening programmes, requiring more extensive treatment or surgery due to late presentations and untreated potentially life-threatening conditions. There were no significant differences in difficulty attending, barriers experienced or adverse outcomes between formally diagnosed and self-identified autistic respondents.

Conclusions Reduction of healthcare inequalities for autistic people requires that healthcare providers understand autistic perspectives, communication needs and sensory sensitivities. Adjustments for autism-specific needs are as necessary as ramps for wheelchair users.

INTRODUCTION

Autism is a common neurodevelopmental condition affecting 1%–2% of the population.1 While autism is lifelong and heterogeneous in presentation, most autistic people are adult, do not have intellectual disability and are likely to be undiagnosed.2 Doctors may underestimate the number of autistic patients under their care.3 4 Autistic adults have poor physical and mental health compared with the general population.5 Most medical conditions are more prevalent in the autistic population,6 7 including diabetes, hypertension and obesity.8 Autistic people experience premature mortality.9–11 Life expectancy is potentially reduced by 16–30 years, with increased mortality across almost all diagnostic categories.9 In-hospital mortality is also increased.12 Autistic people are over two times as likely to use emergency departments13 and to die after attending emergency care and three times as likely to require inpatient admission.14

Alongside increased health needs, autistic people report a greater likelihood that these needs are unmet.15 Pervasive, multifactorial barriers to healthcare access are experienced.15 Some are shared by other disabled people, but autistic patients experience additional autism-specific barriers.16
Patient–provider communication, sensory sensitivities, executive functioning/planning difficulties and prior negative experiences with healthcare providers are important barriers.17,18

In response to primary legislation19 and statutory guidance,20 the Royal College of General Practitioners developed an Autism Patient Charter.21 This recommended: staff awareness and training; autism friendly environment; reasonable adjustments following disclosure or clinical suspicion of autism; patient-tailored communications and behaviour-sensitive accommodations.21 Despite efforts to champion autism, proposals to formalise autism training1,18,21 and specific awareness-raising interventions,21 almost 40% of general practitioners (GPs) report no formal training in autism.22 They also report limited confidence in managing autistic patients.22 Greater autism awareness exists where GPs have personal knowledge of autism, either through a relative or friend on the autistic spectrum, or because they themselves are autistic.22 Communication skills training for healthcare providers may be the most pressing need.4 GPs,22 and hospital specialists3 report difficulties communicating with autistic patients. Only 25% of primary healthcare providers reported high confidence in communicating with autistic adult patients or identifying and making necessary accommodations.4

This study primarily aimed to identify self-reported barriers to accessing primary healthcare faced by autistic adults with a focus on autism-specific communication, sensory issues and procedural considerations. Secondary aims included capturing self-reported adverse health outcomes and the associations between these and reported healthcare access barriers, adding a narrative frame to the existing evidence base around health disparities. This is to our knowledge the largest study of primary healthcare access barriers to date and benefits from a high degree of participatory design by the autistic community.

**METHODS**

**Conception and design**

Here, we present part of a larger cross-sectional study. This work was inspired by a quality improvement project designed to inform autism training for local healthcare providers as part of an ‘Autism Friendly Town’ initiative by AsIAm, Ireland’s National Autism Charity.23,24 In 2018, MD attended Autscape,25 an annual conference by and for autistic people. Participants of all ages are welcome at Autscape, including those who are non-speaking, have high support needs or require full-time care, although the majority of attendees typically have low to moderate support needs. While there, MD distributed an online survey to investigate barriers to primary healthcare in a larger sample of autistic adults, compared with a non-autistic adult comparison group. Nine autistic adults assisted with refining the survey. The resulting survey contained a mix of quantitative questions and free comment boxes. Quantitative questions included yes–no responses, single-item and multiple-item selections from a list and Likert scales. We asked about specific barriers encountered accessing healthcare, reasons for delaying or avoiding a visit and difficulties booking, planning or waiting for a GP visit. We explored the challenges during a consultation, including communication, sensory and organisation issues as well as available social supports. We also explored the impact of such barriers including self-reported consequences of failure to access healthcare and the reasonable adjustments to standard care which facilitate access. We used Google Forms to host the survey.

**Piloting and refinement**

We piloted the survey in 2018. Preliminary analysis revealed a recurring theme of total non-engagement with healthcare providers, despite expressed healthcare needs. Consequently, we altered the survey to add response options applicable to non-attenders. Our research team, comprising autistic and non-autistic GPs, experienced academics and other autistic individuals, adapted and refined the survey into its final 52-item form.

**Sampling, recruitment and data collection**

Autistic adults were recruited using a convenience sampling approach, through Twitter, Facebook and the AsIAm website. We recruited non-autistic controls (without autistic children) through personal and professional contacts of research team members, local area groups and parenting groups on social media. Recruitment took place in August 2019. We provided participant information, with informed consent implied through subsequent completion of the questionnaire. We asked respondents, particularly those who were parents, to respond specifically about seeking healthcare for themselves. For those identifying as autistic, we asked if they were formally diagnosed or self-identified.

**Data analysis**

We used the statistical package ‘R’ to assess significance of between-group associations using a test of proportions and a Wilcoxon-Mann-Whitney U test. Participants who skipped questions were omitted from the analyses of those questions. We intend to present our qualitative results elsewhere.

**Patient and public involvement**

Our study was conducted by an autistic-led research team including autistic medical doctors, using participatory methods. In addition, nine autistic individuals assisted with developing and refining the survey into its final form.
Barriers to access

The most common reason for a GP visit was a physical condition or illness in both groups (86% vs 92%, n.s.). Autistic individuals were more likely to attend for mental health difficulties (61% vs 27%, difference 34%, 95% CI (25.2% to 42.3%), p<0.001). Twenty-two per cent of the autistic respondents usually attended for issues directly related to autism. Compared with 37% of non-autistic respondents, 80% of autistic respondents reported difficulty visiting a GP when needed (difference 43%, 95% CI (34.4% to 51.9%), p<0.001). While difficulty deciding if symptoms warrant a visit was a barrier for both groups (72% vs 65%, n.s.), the most notable difference related to difficulties using the telephone to book an appointment (62% vs 16%). Not feeling understood was a reason to avoid or delay for 56% of autistic respondents compared with 13% of non-autistic respondents. Difficulty communicating with the doctor during the appointment was a barrier for 53% of the autistic group but only 6% of non-autistic respondents. See online supplemental table 1 for specific barriers in order of frequency.

Communication

Alongside difficulty using the telephone, not feeling understood and difficulty communicating with the doctor, autistic respondents reported difficulty communicating with reception staff more often than non-autistic respondents (46% vs 8%, difference 38%, 95% CI (31.5% to 44.6%), p<0.001). Fifty nine per cent of autistic respondents reported difficulty communicating during a consultation ‘all the time’ or ‘frequently’ compared with 12% of non-autistic respondents (p<0.001). Seventy eight per cent of autistic adults reported that ‘anxiety makes it harder to communicate’.

Autistic respondents reported avoiding the telephone (78%), voicemail (61%) and face-to-face verbal communication (30%). Forty one per cent reported that it is ‘easier for me to communicate in writing’ (table 2).

Sensory processing

The waiting room environment was a barrier for 51% of autistic respondents, but only 8% of non-autistic respondents. Specific sensory barriers are detailed in table 3. Sensory issues made communication more difficult for 31% of the autistic group (see table 2). Only 10% of autistic respondents marked ‘none of the above’ to sensory questions compared with 71% of non-autistic respondents.

Perceived stigma

Only 3% of autistic respondents stated they did not feel anxious going to the doctor, compared with 33% of non-autistic respondents (difference 30%, 95% CI (−37.7% to −21.8%), p<0.001). Autistic respondents reported being ‘concerned I won’t be taken seriously when I describe my symptoms’ (67%); worried about ‘wasting the doctor’s time’ (66%) and ‘being considered a hypochondriac’ (65%). They also reported difficulty ‘asking for help’ (63%) and ‘discussing mental health’ (59%). Autistic respondents reported that unusual behaviour or stimulating elicited negative reactions from other patients (15%), reception staff (9%) or medical staff (7%) (online supplemental table 2).

Planning and organising

Autistic respondents reported difficulties with summarising when describing medical problems, with 66% noting the ‘need to give the whole story and not leave anything out’ compared with 12% of non-autistic respondents (difference 54%, 95% CI (47.1% to 60.9%), p<0.001). Autistic respondents reported difficulties with organisation and planning for healthcare, including difficulties ‘making an appointment in advance’ (59%), ‘prioritising my health issues’ (58%) and ‘making changes to my lifestyle or habits’ (56%). Forty five per cent reported forgetting a medical appointment and 30% had attended on the wrong day (online supplemental table 3).

Predictability and control

Autistic respondents reported more difficulty with uncertainty than non-autistic respondents. Particular difficulties included not knowing the wait duration (70% vs 30%, difference 40%, 95% CI (31.5% to 48.7%), p<0.001), what would happen during the consultation (63% vs 16%,

GP, general practitioner.
difference 47%, 95% CI (39.7% to 54.7%), p<0.001), which doctor they would see (58% vs 24%, difference 33%, 95% CI (25.0% to 41.8%), p<0.001) and the consultation length (40% vs 8%, difference 32%, 95% CI (25.6% to 38.4%) p<0.001).

Support needs
Autistic adults reported physical mobility needs (16%) and unmet support needs in primary care, for example, ‘needing a support person to come with me’ (21%). This extended to secondary care: 17% had no one to support unexpected hospital admission, collection from hospital (20%) or home care following discharge (26%) (online supplemental table 4).

Adverse consequences
Autistic respondents reported adverse consequences more frequently than non-autistic respondents, including untreated mental (69%) and physical (63%) health conditions. Notably, 60% were told they ‘should have seen a doctor sooner’ and 47% ‘did not attend referral to a specialist’. Thirty-six per cent ‘required more extensive treatment or surgery’ and 34% did not access treatment for a ‘potentially serious or life-threatening condition’. Additionally, they were less likely to ‘attend on schedule for screening programmes’ than the non-autistic respondents (39% vs 21%, difference 18%, 95% CI (9.8% to 26.2%), p<0.001) (figure 1).

Compared with autistic respondents who had no difficulty visiting a doctor, those who experienced difficulty (80%) reported more untreated mental and physical health conditions (p<0.001). They were also more likely to not attend specialist referral (p<0.001), to need more extensive treatment (p=0.009), to experience untreated life-threatening conditions (p=0.006) and to not attend screening (p=0.028) (figure 2). Four per cent of autistic respondents reported no access to primary healthcare and did not attend any doctor at all. This group differed from the non-autistic respondents who reported no access to primary healthcare (5%) in two areas: all had difficulty visiting the doctor when needed, compared with 50% of non-attending non-autistic respondents (p=0.002); and 95% of autistic non-attenders had experienced at least one delayed treatment outcome, compared with 43% of non-attending, non-autistic respondents (p=0.01). There were no significant differences in difficulty attending a GP, the barriers experienced or adverse outcomes between formally diagnosed and self-identified autistic respondents.

Facilitators
While most respondents (67% vs 65%) reported booking an appointment online would facilitate access, autistic patients selected a need to ‘email my doctor in advance with a description of the issue I need to discuss’ (62%), ‘wait in a quiet place or outside until my turn’ (56%) and ‘book an appointment by text’ (41%). Some autistic

GP, general practitioner.
individuals would benefit if they ‘could book the first or last appointment’ (41%) or had a ‘sensory box available in the waiting room’ (16%) (online supplemental table 5).

Despite the outlined difficulties of visiting their doctor, autistic individuals felt that their relationship with their GP was ‘very important’ or ‘important’ significantly more than non-autistic respondents (70% vs 56%, \( p=0.001 \)), but only 33% of autistic respondents reported a good relationship with their doctor \( (p<0.001) \). Only 62% of autistic individuals reported that their doctor knew they were autistic. Twenty two per cent were unsure, whereas 16% had not disclosed their diagnosis. Autistic respondents appreciated GPs who ask direct questions, give clear explanations, are honest about not understanding autism but know that autism is not a mental illness.

**Geographical variations**

Some barriers to access for autistic respondents varied by geographical location (UK vs elsewhere in the world). Autistic respondents from the UK had more difficulty using the telephone to book appointments (66% vs 54%, \( p=0.012 \)), more difficulty communicating with reception staff (52% vs 37%, \( p=0.002 \)) and were less likely to experience no barriers to access at all (0.3% vs 2.8%, \( p=0.038 \)). Autistic respondents from the UK also found it harder to see a known or preferred doctor (58% vs 29%, \( p<0.001 \)), reported longer waits to get appointments (59% vs 33%, \( p<0.01 \)) and found their online appointment booking systems more confusing (26% vs 10%, \( p<0.001 \)). However, they were less likely to report no access to online booking systems compared with those from elsewhere in the world (26% vs 42%, \( p<0.001 \)). There were no other significant differences for autistic respondents by geographical location.

There was only one significant geographical variation in self-reported adverse outcomes. For autistic respondents, those in the UK were less likely than those from elsewhere in the world to miss/not attend specialist referrals (43% vs 55%, \( p=0.019 \)).

![Figure 2 Adverse outcomes according to difficulty attending a GP.](http://bmjopen.bmj.com/)

![Table 4 Barriers and outcomes associations for autistic respondents.](http://bmjopen.bmj.com/)
Associations between barriers and outcomes for autistic respondents

Table 4 outlines associations between reported barriers and outcomes for autistic respondents. There were no significant associations between any adverse outcomes and difficulty deciding if symptoms warrant a GP visit, not having an online booking system, having a confusing online booking system, having a long wait to get an appointment or having enough time to visit a doctor. In contrast, difficulty communicating with reception staff and difficulty communicating with the doctor during appointments were both significantly associated with all adverse outcomes.

Difficulty using the telephone to book an appointment was significantly associated with all adverse outcomes apart from having to undergo more extensive treatment or surgery than if they had attended sooner. Challenges with the waiting room environment were significantly associated with all adverse outcomes apart from missing specialist referrals and having a potentially serious or life-threatening condition for which they did not access treatment. Difficulty planning an appointment in advance was significantly associated with all adverse outcomes apart from having a potentially serious or life-threatening condition for which they did not access treatment, and having to undergo more extensive treatment or surgery than if they had attended sooner. Needing a support person to attend appointments was significantly associated with all adverse outcomes apart from having a telephone which is a distilled, concentrated essence of verbal communication. Communication was also impaired by anxiety and sensory issues. We linked those barriers to self-reported adverse outcomes. Our data indicated that autistic people may present for healthcare later in the natural course of an illness. Autistic participants reported reduced attendance for screening, late presentations, missed opportunities for early detection and more extensive therapy being required. They also delayed or avoided healthcare because they did not feel understood by their doctors. Furthermore, a substantial minority of autistic adults did not disclose their autism diagnosis, which may impede identification of their autism-specific needs. These barriers may have real consequences, as evidenced in reduced life expectancy, and higher levels of physical and mental health conditions among autistic people.

Comparison with the existing literature

This study confirms the findings of Vohra, Raymaker and several recent reviews, which all identified three groups of barriers: (1) patient-level factors; (2) provider-level factors and (3) system-level factors. Our study stratifies individual barriers from the perspective of autistic individuals. We couple these barriers to self-reported adverse consequences, highlighting factors that may lead to excess morbidity and mortality in the autistic population.

Strengths and limitations

Our study arose from a community-identified need to develop autism awareness training for healthcare providers. It benefited from an autistic-led research team, including autistic doctors, using participatory methods. Our study provided a unique picture of autistic adults’ healthcare experiences, including those entirely excluded from healthcare due to access barriers. In particular, we highlighted the difficulties with using the telephone which is a distilled, concentrated essence of verbal communication.

As we used a convenience sample and self-report survey, generalisability of the data may be limited. Respondents required the ability to complete the survey, which excluded those with reduced ability to self-report. While we did not set out to create a validated tool, our survey may have benefited from some validity and reliability testing. As the initial quality improvement questionnaire was undertaken in the UK, we did not include issues specific to other healthcare systems, such as cost or insurance. Our analyses did not account for potential confounding factors, such as ethnicity or socioeconomic status. Female participants were over-represented in both groups, which is not unusual for online surveys, but it is interesting given the higher rate of autism diagnosis in men. While we noted significant gender differences in relation to non-binary participants, these participants were almost all autistic and we were, therefore, unable to attribute differences to gender identity or autism with

Toolkit includes a publicly available online programme, lemmatic for autistic adults. The AASPIRE Healthcare with a vulnerable population, similar approaches care facilitators in general practice have shown benefit and researched. Social care interventions and health-toolkit in NHS General Practice should be considered healthcare accommodations. Adaptation of such a which generates a computerised report of required accommodations.27 Our data suggest that this could be problematic for autistic adults. The AASPIRE Healthcare Toolkit includes a publicly available online programme, which generates a computerised report of required healthcare accommodations. Adaptation of such a toolkit in NHS General Practice should be considered and researched. Social care interventions and healthcare facilitators in general practice have shown benefit with a vulnerable population, similar approaches could benefit an autistic population. The significant difficulties among the small number of autistic people not registered with any GP indicate a need for further research into this group.

Implications for research
Our study suggests a need for personalised approaches to healthcare access. A prior study investigated using a previsit telephone call to identify individualised accommodation.25 Our data suggest that this could be problematic for autistic adults. The AASPIRE Healthcare Toolkit includes a publicly available online programme, which generates a computerised report of required healthcare accommodations. Adaptation of such a toolkit in NHS General Practice should be considered and researched. Social care interventions and healthcare facilitators in general practice have shown benefit with a vulnerable population, similar approaches could benefit an autistic population. The significant difficulties among the small number of autistic people not registered with any GP indicate a need for further research into this group.

Implications for clinical practice
Based on online supplemental table 5 and the lived experience of the autistic members of our research team, figure 3 outlines our proposed elements of an autism friendly practice. Such adjustments may minimise anxiety, manage sensory issues and ensure mutual understanding—promoting clear, unambiguous communication. Autism friendly practices should employ a personalised approach, with a healthcare access needs assessment and, where possible, a specialist liaison nurse or facilitator.

Implications for policy
Given the identified barriers, the extension of annual health checks to autistic adults and the recently announced Oliver McGowan Mandatory Training in Learning Disability and Autism are welcome. These will likely bring important benefits provided they are informed by the autistic community and autistic healthcare providers. Autism registers in GP practice have been recommended. The success of such initiatives will likely depend on greater awareness by medical practitioners of autistic culture and communication needs. Specific training for GPs during core training and continuing professional development may be beneficial. GPs with a special interest in autism should be facilitated to develop their skills, but management of general health needs and co-occurring conditions fall within the remit of every GP. Implementing existing autism legislation or development where lacking is required in order to reduce health inequities for autistic people.

CONCLUSIONS
Autistic people face barriers accessing the healthcare system, followed by difficulties interacting with healthcare providers, which may contribute to known healthcare disparities, including increased morbidity and mortality. Our study has highlighted a variety of specific barriers to accessing primary healthcare for autistic adults, including use of the telephone to book appointments, not feeling understood, and difficulty communicating with doctors as well as sensory and organisational issues, which impede healthcare access. We identified a variety of significant associations between self-reported barriers to healthcare access and adverse outcomes for autistic respondents. One of our most impactful findings was the lack of any significant differences between formally diagnosed and self-identified autistic respondents in difficulty attending a GP, barriers experienced or self-reported adverse healthcare outcomes. Progress towards eliminating healthcare disparities for autistic people may be achieved by understanding the healthcare experiences and access barriers for this vulnerable patient group. These barriers represent not so much a failure to deliver or to avail of healthcare, but a lack of intersection between the communication patterns of autistic healthcare users and non-autistic providers. Reasonable accommodations are legally and morally required. Adjustments for communication needs are as necessary for autistic people as ramps for wheelchair users.

Acknowledgements We are indebted to Professor Louise Gallagher for her guidance during the early stages of this project. We acknowledge the input received from the autistic adult community recruited via local groups and online contacts during the development of the online survey. Assistance with content, structure and proofreading of the surveys was received from nine autistic adults in Ireland and the UK. We received assistance from members of peer support group ‘Autistic Doctors International’. We also thank Dr David Hillebrandt, Dr Natalie Teasdale, Elaine McGoldrick and Karen Leneh Buckle for their assistance during this project.

Figure 3 Autism friendly general practice.
CONTRIBUTORS Conception and design of study: MD, SN, JO’S, with contributions from those listed in acknowledgements. Acquisition of data: MD, SN, JO’S. Analysis of data: SN, MD, SCKS. Interpretation of data: MD, SN, JO’S, LC, MJ, WC, SCKS.

Drafting and revising the manuscript: MD, SN, JO’S, LC, MJ, WC, SCKS. Approval of the version of the manuscript to be published: MD, SN, JO’S, LC, MJ, WC, SCKS. MD is the Guarantor of this work.

FUNDING We are grateful to AsIAm, Ireland’s National Autism Charity and Scally’s SuperValu, Clonaklity, for the funding to enable open access publication.

COMPETING INTERESTS None declared.

PATIENT CONSENT FOR PUBLICATION Not applicable.

ETHICS APPROVAL This study involves human participants and was approved by SJH/TUH Joint Research and Ethics Committee REC: 2019-06 Chairman’s Action (17). Participants gave informed consent to participate in the study before taking part.

PROVENANCE AND PEER REVIEW Not commissioned; externally peer reviewed.

DATA AVAILABILITY STATEMENT Data are available upon reasonable request. All data relevant to the study are included in the article or uploaded as supplementary information.

SUPPLEMENTAL MATERIAL This content has been supplied by the author(s). It has not been vetted by BMJ Publishing Group Limited (BMJ) and may not have been peer-reviewed.
