Background It has been suggested that prehospital providers need to be situationally aware in order to reduce human error. By reducing human error, patient outcomes may be improved. Research during the COVID19 pandemic has been difficult and while many projects were put on hold, the authors created a novel manner in which to complete this study and measure SA – through online simulation.

Method This was a mixed-methods explanatory sequential study where prehospital providers participated in an online simulation. The situational awareness global assessment technique (SAGAT) was utilized during periodic freezes in the simulation where the participants would answer questions related to the environments of the patient and the scene. Questions were focused on perception, interpretation, and prediction. Following the simulation, participants provided feedback during interviews.

Results The providers did not possess high levels of SA. Overall SA was 45% (p-value, .162), where participants performed best at perception with a steady decline to interpretation and then prediction. Those with higher levels of education did perform better, although this was not statistically significant, (p-value, .09). Those with more experience initially had higher SA but then tended to decrease with more experience (p-value, .24). Participants did feel satisfied with the online simulation and also felt that the simulation and SAGAT were beneficial to their continuing education and improving their care in the field.

Conclusion Prehospital providers are not situationally aware during online simulation. They focused on the surroundings at first, but did not focus as much on the patient. The SAGAT can be utilized in an online format and may possibly enhance overall performance. Further research is needed to determine if higher levels of education and experience play a role in prehospital SA.

Cardiac arrest

249 THE ASSOCIATION OF COMORBIDITIES AND SURVIVAL AFTER OUT-OF-HOSPITAL CARDIAC ARREST IN DENMARK

1,2,3ST Søndergren*, 1,4SG Møller, 6CT Pedersen, 1,3,5FF Folsø, 1,2AK Ersbøll. 1Copenhagen University Hospital – Emergency Medical Services Copenhagen, Denmark; 4National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark; 2Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; 2Department of Cardiology, Copenhagen University Hospital – Bispebjerg and Frederiksberg, Copenhagen, Denmark; 3Department of Cardiology, Copenhagen University Hospital – Herlev and Gentofte, Hellerup, Denmark; 6Department of Cardiology, Nephrology and Endocrinology – North Zealand, Hilleroed, Denmark

Background An increase has been observed in 30-day survival of out-of-hospital cardiac arrest (OHCA) in the past 18 years from 4% to 14% in Denmark, but OHCA survival remains low. We investigated how pre-existing comorbidities affected 30-day survival and time-to-death of OHCA patients.

Method This is a retrospective registry-based study with use of nationwide registries. Data on OHCA (2001–2015) were obtained from the Danish Cardiac Arrest Registry, data on the most clinically relevant comorbidities were collected from the Danish National Patient Registry and the Danish National Prescription Registry for up to 10 years prior to their arrest. Data on time-to-death was collected from the Danish Cause of Death Registry. Analysis was performed with use of several generalised linear models.

Results OHCA patients with AMI, ischemic heart disease (IHD), arrhythmia, and heart failure, had a 30-day survival of 7.39 [6.87; 7.95], 5.43 [4.90; 6.02], 2.87 [2.66; 3.09], 1.76 [1.60; 1.93] and 1.51 [1.39; 1.65], respectively, presented as odds ratios (OR). Patients with the co-existing conditions i) AMI and arrhythmia or ii) arrhythmia and IHD
