258 CLINICAL EVALUATION OF THE NOVEL ‘FULLSTOP’ Tourniquet USING REAL TIME DOPPLER ULTRASOUND IN A HUMAN MODEL

R Lyon*, B Earle-Wright. Emergency Department, Royal Infirmary of Edinburgh, UK
10.1136/bmjopen-2022-EMS.15

Background Major haemorrhage following trauma is a leading cause of preventable death. In the case of major haemorrhage from a limb, early application of a tourniquet can be life-saving. Tourniquets often need to be applied by lay persons, prior to the arrival of emergency medical services, in order to prevent exsanguination. A tourniquet needs to be completely reliable and easy to apply rapidly. We sought to evaluate the novel FullStop tourniquet (Safeguard Medical) in a human model.

Method A standard training session covering the FullStop method of application was provided. The FullStop tourniquet was applied to the upper arm of an adult human. Colour doppler ultrasound was used to identify the radial artery and visualise the radial pulse prior to tourniquet application and then following application. The time to full apply the FullStop was recorded. Successful application was defined as absence of any arterial pulsation on ultrasound.

Results 28 medical professionals participated in the study. They included doctors (n=9), nurses (n=8), medical students (n=5) and paramedics (n=6). Median time to application was 24 seconds (IQR 19–28 s). All (n=28, 100%) applications were successful in achieving complete occlusion of arterial flow in the arm.

Conclusion The FullStop tourniquet was rapid to apply and entirely effective in achieving complete occlusion of arterial flow in the upper limb. Further research is warranted to explore how effective the FullStop would be for lay person responders.

262 PARAMEDICS’ PERCEPTIONS OF JOB DEMANDS AND RESOURCES IN FINNISH EMERGENCY MEDICAL SERVICES: A QUALITATIVE DESCRIPTIVE STUDY

1,2CR Ericsson*, 3,4V Lindström, 6,7A Rudman, 2,8H Nordquist. 1Department of Healthcare, Arcadia University of Applied Sciences, Helsinki, Finland; 2Faculty of Medicine, University of Helsinki, Helsinki, Finland; 3Department of Neurobiology, Care Sciences and Society, Section of Nursing, Karolinska Institute, Stockholm, Sweden; 4Samaritain Ambulance, Stockholm, Sweden; 5Sophiahemmet University, Stockholm, Sweden; 6Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden; 7Department of Health and Welfare, Dalarna University, Falun, Sweden; 8Faculty of Social Sciences, University of Helsinki, Helsinki, Finland; 9South-Eastern Finland University of Applied Sciences, Kotka, Finland
10.1136/bmjopen-2022-EMS.16

Background Paramedic professionals’ fatigue is rising 1,2. Stress factors show increased risk for burnout and fatigue, leaving the profession, decreased performance and risk for patient safety. (1) Meanwhile, paramedics’ strong community of practice, autonomy of practice and a sense of professional respect are important factors in forming psychological resilience.3 This study aimed to explore Finnish paramedics’ perceptions of job demands and resources.

Method A cross-sectional descriptive study with qualitative design, utilizing an inductive constructivist approach. The study used reflexive thematic analysis, by Braun and Clarke, to analyse two data sets of responses from professional Finnish paramedics; open-ended questions from a web-based survey (n=174) and essays written by masters-degree students (n=34).

Results The results were categorized into job demands or resources, as defined in Job Demands and Resource model by Demerouti and Bakker. Themes identified as paramedics’ job demands were continuous stress from mentally burdening work (high workload, environmental stress factors and bearing patients’ and relatives’ emotional burden), uncertainty under expectation pressures (sense of inadequacy and a pressure to perform) and organizational lack of support. Themes identified as paramedics’ job resources were pressure management strategies (distancing coping mechanisms, ability to handle clinical demands and ability to affect own work) and professional self-actualization (psychologically safe work community, professional sense of pride and internal drive to professional development).

Conclusion Finnish paramedics exhibit both job demands and resources. Performance pressure, uncertainty and emotional burden and also environmental hazards and psychological safety in communities. This indicates a need to address not only physical aspects of the paramedic work but also early stage performance expectations and organizational cultures.

Pain and trauma

267 REVIEW OF PREHOSPITAL PAIN MANAGEMENT IN PEDIATRIC TRAUMA

SI Montero*, CL Villamor, JA Lara, E Corral, F Miguel, D Bélangier-Quintana. SAMUR Civil Protection, Emergency Medical Service. Madrid, Spain
10.1136/bmjopen-2022-EMS.15

Background Adequate management of pain in children if often a neglected aspect, usually underevaluated and under-treated. This study is a continuous review to see if pharmacological methods provided during the prehospital care of pediatric trauma patients is proper.

Method Retrospective study of clinical records of children up to 18 year of age, assisted between 2017 and 2018. Mild pathologies excluded. Epidemiological variables: age, gender,
Quantitative variables: central and dispersion measures. Inferential statistical analysis: relationship between quantitative variables, Student’s t test and categorical variables, and Chi square. 95% confidence intervals, p<0.05. SPSS 20.

Results Total of 725 patients. Median age was 13 years (IQR 8–15). 70.9% males (514). Critically ill patients constitute 5.8% (42). Children received analgesia: 43.6% (316); <4 years: 17.3% (14), 5 to 11: 36.7% (80) and 12 to 18: 52.1% (222). IV route: 70.8% (240), intranasal: 21.4% (74). Fentanyl was used in 73.4% (232), Paracetamol 23.1% (73), Ketorolac 22.8% (72). IV mean doses: 1.9μg/Kg, 15.1mg/Kg, 0.34mg/Kg respectively. Analgesia with PTS <9: 76.5% and PTS ≥ 9: 42.8%. NRS used in 12.5% (91); median initial: 8 (IQR 7–9) and after analgesia: 3 (IQR 2–4).

Conclusion IV opioids are the most widely used. Doses administered by weight are correct. The use of analgesia predominates in critically ill patients although not as high as indicated in international guidelines. We observed undertreatment in the groups of younger children, possibly due to a higher incidence of TBI. Alternative routes to IV administration could increase the use. Although pain scales were seldom used, the results show notable reduction of pain.

MATHEMATICALLY OPTIMISED PUBLIC ACCESS DEFIBRILLATOR PLACEMENT – FAIRNESS OR ACCESSIBILITY?

1KHB Leung*, 2DL Lac, 3TCY Chan, 4GR Clegg. 1University of Toronto, Canada; 2University of Edinburgh, UK; 3Scottish Ambulance Service, UK

10.1136/bmjopen-2022-EMS.18

Background Mathematical optimisation can be used to maximise public access defibrillator (PAD) accessibility for out-of-hospital cardiac arrest (OHCA). It is unclear whether enforcing ‘fairness’ (defined as parity of PAD accessibility) across city wards would impact resulting PAD accessibility compared to an unconstrained approach.

Method We included all suspected OHCA responses and 424 existing PADs. PADS registered with SAS as of Feb. 2020. We computed the accessibility (defined as within 100 m of OHCA) for existing PADS and developed a mathematical model to select locations for additional PADS under two scenarios: (1) select optimal locations across whole cities, and (2) select optimal locations distributed equally between city wards. Up to 20 additional PAD locations per ward were considered. For both scenarios, we compared PAD accessibility on out-of-sample OHCA using McNemar’s test and fairness across wards using the Nash social welfare function.

Results We identified 14,674 OHCA responses and 424 existing PADS. PADS were within range of 11.0% of OHCA (0.4–2.0% per city). Optimising new PAD locations per city, regardless of wards, increased PAD accessibility to 15.4% of OHCA (14.9–17.9% per city). Constraining an equal number of PADS in each ward resulted in accessibility loss of 0.2–1.4 percentage points depending on the quantity of PADS placed (P<0.05 for 18 of 20 cases) but improved fairness values by up to 89% for smaller quantities of PADS.

Conclusion Enforcing ward-level parity when selecting optimal new PAD locations results in fairer but less accessible PADS for OHCA.

OPTIMIZING RESIDENTIAL AUTOMATED EXTERNAL DEFIBRILLATOR COVERAGE BY TARGETING SOCIAL HOUSING AREAS

1,2AJ Jørgensen*, 1,2S Kjølbye, 3,P Ett, 4,M Krammel, 1,2NB Christensen, 4,K Ringgren, 7C Torp-Pedersen, 1,F Folke, 4,5CH Hansen. 1Emergency Medical Services Copenhagen, Denmark; 2Faculty of Medicine, Copenhagen University, Denmark; 3Department of Emergency Medicine, Medical University of Vienna, Austria; 4PULS – Austrian Cardiac Arrest Awareness Association; 5Emergency Medical Service Vienna, Vienna, Austria; 6Department of Cardiology, Aalborg University Hospital, Denmark; 7Department of Cardiology, North Zealand Hospital, Denmark; 8Department of Cardiology, Rigshospitalet, Denmark

10.1136/bmjopen-2022-EMS.19

Background Strategies for deployment of automated external defibrillators (AEDs) in residential areas are warranted. Social housing is widespread in Europe, has a high frequency of socio-economic predictors for out-of-hospital cardiac arrest, and consists of well-defined units with local leadership. We aimed to optimize AED placement by targeting social housing in Vienna and Copenhagen.

Method Population density was obtained from Urban Atlas®; AED and social housing data from Vienna through City of Vienna, and from Copenhagen through the Danish AED Network and the National Building Foundation, respectively. From April 2020, all 24-hour accessible AEDs in residential areas were included. AED coverage was defined as number of inhabitants within 100 meters of an AED. AEDs were randomly distributed in social housing accounting for current AEDs and a density of 0.5 AED/hectare. Current vs. optimized AED coverage were compared in Vienna and Copenhagen.

Results In Vienna vs. Copenhagen, respectively, 25% (n=492,752) vs. 31% (n=304,966) of the population live in social housing areas, characterized by a high average population density: 361 inhabitants/hectare (all residential areas 173) vs. 142 inhabitants/hectare (all residential areas 71). AED density was 0.02 AED/hectare (271 AEDs) vs. 0.12 AED/hectare (1,641 AEDs) for Vienna vs. Copenhagen, and AED coverage was 358 (95%CI:309;414) inhabitants/AED vs. 119 (95%CI:114;128) inhabitants/AED, respectively. Application of the AED optimization model in social housing increased population coverage by nearly 2-fold: Vienna to 661 (95%CI:628;695, p-value<0.0001) inhabitants/AED; Copenhagen to 243 (95%CI:231;255, p-value<0.0001) inhabitants/AED.

Conclusion AED deployment targeting social housing may be a feasible strategy for optimizing coverage of residential out-of-hospital cardiac arrest.
