Competency in nursing practice: a concept analysis

Majd T Mrayyan,1 Hamzeh Y Abunab,2 Abdallah Abu Khait,1 Mohammad J Rababa,3 Sami Al-Rawashdeh,1 Abdullah Algunmeeyn,4 Ahmed Abu Saraya

ABSTRACT
Objective Competency denotes the ability to execute a certain task or action with the necessary knowledge. Competency definitions and measurements are challenging for nursing and other professions due to their multidimensional aspects. This study aimed to clarify the concept of competency in nursing practice and propose an accurate definition.

Design Walker and Avant’s approach was used to elucidate the concept of competency in nursing practice.

Data sources ScienceDirect, PubMed, ProQuest, Scopus and CINAHL were searched from 1 January 2000 to 31 December 2021.

Eligibility criteria We included studies with the keywords: “concept analysis”, “competence”, “competency” and “nursing”. The search was limited to full-text studies written in English that used theoretical and empirical approaches.

Data extraction and synthesis We extracted the concept’s uses, defining attributes, and the consequences and antecedents of the concept.

Results 60 articles were included from the search process; after excluding duplicates and works unrelated to the study aim and context following the full-text screening, 10 articles were included in this concept analysis. The common defining attributes of competency were knowledge, self-assessment and dynamic state. Competency in nursing practice had many reported positive consequences that include but are not limited to: improving patient, nurse and organisational outcomes.

Conclusions Nurses can benefit from the result of this analysis in practice to implement professional care, in particular clinical contexts and situations to enhance patients’ health.

INTRODUCTION
Definition of competency and role in education ‘Competency’ is the capability of any given person or professional to execute a certain task or action while having the necessary training and education to do so.1 Another essential term is ‘competency-based education’, defined by the American Association of Colleges of Nursing as ‘a process whereby students are held accountable to the mastery of competencies deemed critical for an area of study’. It is ‘anchored to the outputs of an educational experience vs the inputs of the educational environment and system’ (p. 4).2 On the other hand, Zumstein-Shaha and Grace3 purported that nursing education aimed to achieve learning outcomes in the classroom and during clinical practice. It is an example of operation and structure. Nursing education is based on competency frameworks from other professions, such as in the USA and Switzerland, in contrast to this well-established method. This is a concern since the fundamental idea and philosophy conflict with those of the nursing field. Competency may signify several aspects of this approach.

Competency: theoretical background and role in clinical practice
Nurses must maintain their competency as they are on the front when carrying out tasks for their clients and performing the duties of their profession.3 4 Nurses have legal and ethical obligations to maintain their competency. Competency helps them perform their duties while integrating multiple elements, including knowledge, techniques, attitude and thinking ability.5 ‘Competency’ will result in positive outcomes for patients, nurses, their profession and organisations.5

Competence is a concept used interchangeably with competency in the literature.1 However, competence reflects an individual’s actions and abilities to fulfil job responsibilities.3 In contrast, competency represents an individual’s performance in specific
circumstances to implement successfully. Competency has always been the core goal of nursing, in contrast to other aspects of healthcare in which getting the job done has always been the primary focus. 

Although ‘competence’ has been extensively discussed in the nursing literature, 5 6 it has moved into the contemporary term ‘competency’. 5–7 Competency in nursing practice is a behaviour-oriented term, while competence is a task-based term based on the behaviourism view of the profession and trait theory. More specifically, while ‘competency’ is knowing behaviours, judgement and skills to perform duties efficiently, 4 5 ‘competence’ is the ability to do something successfully. 1

There are several assumptions about competency: (1) a comprehensive conceptualisation of competence includes skills, knowledge, attitudes, levels of sufficiency and performances; 4 6 9–13 (2) competency is an indicator of an extent of capability assumed to be sufficient in a specific task; 7 11 (3) competency can be achieved; thus, training is required; 3 10 (4) performance regarding specific behaviours may be measured to check for competency; 3 4 6 7 11 14 and (5) competency is crucial for nurses to make safe clinical judgements. 3 10 13 16 Recent reference denoted ‘competency’ as the ability to execute a certain task or action in conjunction with the necessary knowledge. 1 17

In response to the changing healthcare environment, competency-based education emerged as a key policy in industrialised countries in the mid-1960s. Worldwide, nursing education has moved to a competency-based curriculum due to the move from ‘training’ to ‘education’ that occurred in the 1980s and 1990s. 19 20 In 2005, a project developed a competence matrix for nurses working in clinical settings within the European Union. 21 The competency-based practice emerged as a response to competency-based education. Competency has implications in nursing practice as the health and safety of patients are directly impacted by competency, whereas the absence of competency may result in harmful medical consequences. It contributes to safe care and protects nurses’ credibility, enhancing their proficiency and independent work. 6 10 22

The International Council of Nurses (ICN) supports regulation to ensure safe and competent nursing practice and safeguard the public. The scope of nursing practice defines its dimensions and bounds, and the profession must clearly describe its practice parameters to meet general societal requirements. Otherwise, the practice may become limited and fragmented, leaving needs unsatisfied. 23

The term ‘competency in nursing practice’ was used for the current concept analysis. ‘Concept analysis’ used a thematic method for presenting the findings. 24–26 Walker and Avant’s approach was used in the concept analysis as it is the simplest and most understandable method used for concept analysis.

Problem with competency in nursing and rationale for the study

No mechanism exists for most healthcare facilities to ensure that practitioners remain updated with current best practices. Nursing schools struggle to determine the best ways to educate students who demonstrate entry-level competencies. Employers struggle to determine the best ways to validate entry-level competencies and determine specialty competencies. Because the idea of competency in nursing practice is still developing and continues to suffer from a lack of clarity and operationalisation, we must have a much better grasp of the antecedents, attributes and consequences of this concept.

Competency in nursing practice is crucial for optimal health outcomes in general and advanced nursing practice. 15 Yet, the clear meaning of competency is still questionable, as this concept is multifaceted and derived from distinct attributes. 3 6 The multidimensional features of this concept complicate the process, and this conceptual unclarity has not facilitated effective communication among nurses and other professionals. 19 Regarding its actual meaning, ‘competency’ is an elusive rather than an exclusive entity. 5

Although it is one of the basic milestones in nursing practice, few studies analysed and measured competency. 4–6 10 25 27–28 It is integral in many nurses’ educational programmes but has no universal definition. 5 6 10 29 Competency definitions are challenging for nursing and other professions. 13 16

Based on the prior literature, it is clear that competence is a mix of knowledge, skills and attitude in numerous pieces of literature. However, the purpose of this research is to provide the findings from a concept analysis that looked at many aspects of competence, specifically how those aspects have changed over the last decades in terms of interpretation, application and transformation. The purpose of this concept analysis was to review and evaluate the data that were available on competency in nursing practice. The goal is to discover any important factors that shape professional understanding and, in turn, shape the actual application of that understanding in modern nursing practice.

METHODS

Concept analysis method

The eight-step model of concept analysis of Walker and Avant 26 was used to explore the concept of competency in nursing practice: (1) choosing the concept; (2) outlining the objectives of the analysis; (3) recognising the concept’s uses; (4) selecting the concept’s defining attributes; (5) constructing a model case; (6) constructing related, borderline and contrary cases; (7) defining the consequences and antecedents of the concept; and (8) determining empirical referents. 26 A concept analysis is usually used for theory development and understanding and operationalising certain terms. 10 24 26 30 Although the authors’ intention is not to develop a theory of the
concept of competency in nursing practice, applying an iterative analysis process will help remediate the lack of consensus on the key attributes of this concept.

Data sources
Five electronic databases were selected: ScienceDirect, PubMed, ProQuest, Scopus and CINAHL. The reference list of the selected studies was also reviewed to consider further resources. The keywords with Boolean operators used in the search process were: “concept analysis”, “competence”, “competency” and “nursing”. The search was limited to full-text studies written in English that used theoretical and empirical approaches published between 1 January 2000 and 31 December 2021. All studies that did not comply with these inclusion criteria were excluded.

The titles and abstracts found using the search strategies were evaluated separately by the two authors. When an abstract was first evaluated, it was discarded if it was determined that the article did not match the idea being studied. The authors determined whether or not the abstract should be included if there was any uncertainty about it meeting the inclusion requirements of the concept under study. After that, the whole texts of the selected articles were obtained. The authors independently screened the chosen full-text publications and, where necessary, checked and verified the results against the inclusion criteria.

Selecting the concept
Different terms related to ‘competency’ and ‘competence’ in nursing were used in the reviewed literature, such as ‘cultural competence’,24 ‘ethical competence’,31 ‘moral competency’,32 ‘professional competence’433 and ‘clinical competence’.4 As seen, ‘competency’ per se was not commonly used.

Competency is important in all professions, including nursing.6 9 It directly influences the safety and health of patients.6 22 24 Diminished competency can result in serious medical errors for patients.7 Competency in nursing practice should always be assessed to address aspects of professional development, meet learning needs and provide the best care for patients.6 10

Competency in nursing practice should always be assessed to address aspects of professional development, meet learning needs and provide the best care for patients.6 10 The standards for professional competency contain various domains, such as technical, cognitive and emotional aspects of practice, including those unmeasurable domains.6 8 14 However, no agreed-upon definition of competency contains all important domains of nursing practice and the practice of other professions.6 8 14 21 33

Patient and public involvement
None.

RESULTS
Sixty articles were yielded from the search process; however, 50 were identified as duplicates or unrelated to the study aim and context after full-text screening. Finally, 10 articles were included in this concept analysis, as they applied the elements of the studied concept and the eight-step method of Walker and Avant26 and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow chart (figure 1).34 Complete details on the search protocol are listed in online supplemental file 1, and a summary of selected articles is provided in online supplemental table 1. To comprehensively analyse a concept, its definitions and uses, defining attributes, antecedents, consequences and empirical referents should be considered. PRISMA 2020 was also used to facilitate transparent and complete reporting of the concept analysis (online supplemental file 2).

Definitions and uses of the concept
The definitions of competency have evolved. Merriam-Webster defines competency as having sufficient knowledge, behaviours, judgement and skills to perform a particular duty.9 Competency was described by Zumstein-Shaha and Grace as the ability of any given person, pending training and instruction, to carry out specific activities or actions.1

The widely acknowledged holism is that nursing competency includes skills, knowledge, professional judgement,
attitudes and values. Given that knowledge and skills are adaptable to various contexts, nurses must integrate and apply their newly learnt knowledge, abilities and personal traits to each clinical practice environment. The scope and standards of nursing practice, the ICN Framework of Competencies for the Nurse Specialist and the graduation success goals as they show the growth of nursing competency can all be used to assess the integrated and holistic nursing competency.

The definition of competency in nursing practice is not universally agreed upon, although most definitions emphasise knowledge, behaviours, judgement, skills, values and attitudes needed to perform professional obligations.

Key attributes of competency

The most important aspect of concept analysis is determining the concept’s defining characteristics, which distinguish this concept from other similar or related concepts. Defining attributes also aid researchers in identifying key qualities that repeatedly appear in a concept and highlighting their significance in the context. Attributes are the traits that have the strongest link to the concept, and they are the terms researchers use to describe the characteristics of concept.

Competency has many attributes (characteristics); however, the common defining attributes of competency in nursing practice in the reviewed literature are knowledge, self-assessment and dynamic state.

Knowledge is one of the important dimensions for assessing competency. Nurses must possess many specialty areas through special education that enriches their knowledge. Nurses with the knowledge and skills provide safe, high-quality care with the best possible outcomes. This knowledge supports their abilities in providing safe, high-quality care. Nurses with the knowledge and skills in specialty areas through special education that enriches their knowledge. Nurses with advanced and specialised education are adaptable to various contexts, nurses must integrate and apply their newly learnt knowledge, abilities and personal traits to each clinical practice environment.

The definition of competency in nursing practice is not universally agreed upon, although most definitions emphasise knowledge, behaviours, judgement, skills, values and attitudes needed to perform professional obligations.

Antecedents of competency

Antecedents are those events or situations that must be presented for the concept to occur. For a nurse to practise competently, the following must be satisfied first: (1) sufficient education, (2) a set of skills and abilities, (3) standards of actions or behaviours, and (4) positive attitudes and responsibility for applying the knowledge in practice.

In the global context, Liu and Aungsuroch reported, in their comprehensive literature review, that the antecedents related to nursing competency are: (1) socio-demographic variables, including work experience, employment status and age; (2) professional-related variables such as self-esteem, research utilisation and critical thinking; and (3) work environment variables such as ethical climate, job satisfaction, practice environment and learning environment.

Also, in the global community, the inductive content analysis yielded 11 components of nursing competency: professional clinical practice, personal traits, cooperation, therapeutics practice, management of nursing care, ensuring safe and quality legal and ethical practice, professional development, communication, leadership, critical thinking and innovation, and teaching-coaching. The researchers elaborated on each component as the following: (1) personal traits identified nurses’ consistent thoughts and behaviours such as accountability and self-control; (2) professional clinical practice focused on applying the holistic nursing care that meets patients’ needs; (3) cooperation and therapeutics practice focused on multidisciplinary team to provide high-quality nursing care; (4) ensuring quality and safety aims at improving the quality of nursing care provided; (5) management of nursing care focused on how nurses provide nursing care; (6) legal and ethical practice when nurses work in the diverse cultural practice environment; (7) innovation.
and critical thinking by which nurses’ decision-making is evidence based; (8) communication is the ability to understand and be understood; (9) ‘leadership’ means that nurses should be able to influence while providing nursing care; (10) professional development by which nurses continue to update their skills and knowledge to adapt to changes in all aspects of work environment; and (11) ‘teaching-coaching’ in which nurses are aware of teaching/learning principles.

While considering the context of nursing practice, using the inductive content analysis, the common and appropriate antecedents of competency were education, knowledge, skills and abilities, standards of actions or behaviours, positive attitudes and responsibility for applying the knowledge in practice.

**Consequences of competency**

Consequences are the outcomes of the concept’s occurrence. Competency models are critical to ensure professionals meet job requirements and produce positive outcomes for themselves, their patients and the organisation. Competency in nursing practice decreases serious medical errors for patients and maintains patient safety. It improves patients’ outcomes and nurses’ clinical judgement. It also improves the accountability and self-assessment of nurses. As a result, competency in nursing practice narrows the gap between education and practice.

**Empirical referents**

Empirical referents embrace those categories of actual manifestations that can suggest the concept’s occurrence in its context and allow quantifying its key characteristics. They can be used in the development of new measurement tools and the review of present ones. Empirical referents can further simplify the concept and facilitate its measurement. Nurses work in complex and varied clinical settings, complicating the measurement of nursing competency. Thus, the definition and measurement of nursing competency differ among researchers and professionals. Competency is also a time-specific and context-related concept. It mandates that nurses maintain their education and skills updated to accommodate society’s evolving requirements and work environments; thus, nurses must maintain contemporary nursing competency.

Various tools have been developed to measure competency. However, the tools and methods used to measure the concept lack rigour. Given the varied definitions of the concept, the challenge remains concerning selecting the research tool.

In their comprehensive literature review, Liu and Aungsu-roch explored different instruments used to assess nursing competency: (1) the European Questionnaire Tool, (2) the Competence Inventory for Registered Nurses, (3) Australian National Competency Standards for Registered Nurses, (4) Competence Scale for Senior Clinical Nurses and (5) Holistic Nursing Competency Scale. Most instruments focused on ‘competence’ rather than ‘competency’. All those instruments have good psychometric properties. Yet, the five developed instruments were designed as self-reported scales, contributing to the bias of nurses rating their competencies. However, self-assessment still serves as a career planning and learning tool; it helps nurses identify the strengths and weaknesses of their practice. The Nurse Competence Scale (NCS) is a common tool used for measuring the competency self-assessment of practising nurses; it is an easy and culturally sensitive tool. The NCS is a 73-item scale with seven subscales: teaching-coaching (16 items), helping role (7 items), managing situations (8 items), diagnostic functions (7 items), ensuring quality (6 items), work role (19 items) and therapeutic interventions (10 items). Items are rated on a Visual Analogue Scale (0–100), with a higher score indicating greater competency levels.

Assessing applied knowledge and skills is crucial for nurses’ optimal competency levels. The Knowledge and Skills Framework was launched in the UK in 2004. This framework required all non-medical, registered practitioners to demonstrate their ongoing professional development and ability to practise by demonstrating this ability against a set of competencies.

Competency is a context-specific as well as a time-specific concept. Garside and Nhemachena and Liu and Aungsu-roch suggested that ‘date-stamping’ qualifications, which are related to a system of updates of 5–10 years, should be seriously considered. Continued ‘exposure’ and ‘performance feedback’ provide continuous development and maintenance of competency and confidence within the designated clinical context. Competency should not be viewed merely as the aptitude for nurses to act efficiently once, and the nurse should deliver their performance constantly to reach a satisfactory standard. In conclusion, developing new tools is required to measure competency in nursing practice as an evolving concept.

**The proposed definition of the concept**

Based on the present concept analysis, ‘competency’ is the ability to execute a certain task or action with the necessary knowledge. It is the dynamic process of acquiring knowledge, behaviours, judgement, skills, values and attitudes to provide patients with effective, safe and quality care. This definition is consistent with the ICN’s (2009) definition of nursing competency and the ‘holism’ view of competency.

**DISCUSSION**

The current concept analysis findings indicate that competency in nursing practice is the ability to deliver safe and quality patient care. It has been claimed there is very much professional freedom in defining nursing competency. Competency does not suddenly occur; nurses must maintain updated knowledge and keep the evolving ‘continuously developing’ status. Nurses also maintain...
specific technical skills and affective and cognitive characteristics; these are crucial antecedents for maintaining competency in nursing practice. Nurses acknowledged that unlimited tasks must not evaluate competency or be too extensive.

Based on the present concept analysis, ‘competency’ is the ability to execute assigned tasks or actions with the necessary knowledge. This definition is consistent with the ICN’s (2009) definition of nursing competency, which focuses on the scope of nursing practice that originally depended on nurses’ knowledge levels. In nursing definitions, there is general agreement that competence reflects the knowledge, comprehension, judgement, cognitive, technical, psychomotor and interpersonal abilities, and personal traits and attitudes. Moreover, this definition is consistent with the ‘holism’ view of competency based on certain elements, knowledge and skills in particular.

Certain antecedents, such as educational preparation for nurses, should precede to develop and maintain competency in nursing practice. Integrating the concept of competency into nursing course syllabi, and conducting educational sessions and training workshops for nursing instructors are important to maintain competent nurses and nursing students. Administrative aid and funding are also crucial to developing and maintaining competency in nursing practice.

Other antecedents related to nursing competency were professional, work environment related and sociodemographic variables. Therefore, nursing managers need to establish and maintain a supportive work environment. Leaders who encourage their employees to learn and teach one another, provide coaching when needed and empower their employees’ professional development will improve their practice competency.

Recent studies reported the consequences of competency concerning patients, nurses and healthcare organisations. These consequences include decreased medical errors, lowered healthcare costs and continuous safety of patients, improved patient outcomes and nurses’ clinical judgement, and increased accountability and self-assessment of nurses. Competent nurses provide patient-centred care, and promote patient empowerment, personal and professional development, and emotional interaction with their patients.

Implications of the findings
The findings of this concept analysis reveal implications for nursing practice, education, research, and organisational and managerial planning. For nursing practice, paying attention to competency is among the main keys of clinical nursing. Competency in nursing practice includes core abilities required to fulfil one’s clinical roles. Thus, it is critical to clearly define the concept to establish a foundation for competent nursing practice.

For nursing education, in-service competency sessions are essential for nurses to expand and update their knowledge and improve their skills. Practice-based learning and individualised learning experiences could be established in in-service competency education programmes. Educators must integrate competency care into the curricula. The profound change in educational policy during the 1980s and 1990s by adopting a competency-based curriculum mandates examining the effects of this curriculum on defining and measuring competency in nursing practice; thus, a policy is warranted. For nursing research, future studies are still needed to examine the impacts of nursing competency on health-related outcomes. Instead of self-rating nursing competency, more objective approaches are recommended to evaluate competencies in nursing practice, such as observing patients, and administrators’ and peers’ evaluations. These different tools are more comprehensive and objective. For organisational and managerial planning, ‘competency in nursing practice’ could be integrated into healthcare organisations’ philosophy, mission and goals.

The organisation will be visible to the public in its competency-related matters. Healthcare organisations should provide necessary programmes to develop nurses and other healthcare providers. Having up-to-date knowledge and skills are essential antecedents of competency in nursing practice.

Study limitations
Some limitations should be acknowledged in this concept analysis. The major shortcoming of using Walker and Avant’s eight-step method is that no particular strategy is recommended for outlining the concept’s uses. However, the rigorous methodology used in this analysis has diminished this limitation. The constructed cases in this analysis were artificially developed, restricting their real-world applicability. Despite these limitations, the current analysis may contribute to creating an agreed language enclosing the concept, which helps nurses discern competency from other closely related concepts such as competence.

Conclusions
Competency is a challenging concept that addresses gaps between theoretical knowledge, education and clinical practice; thus, it warrants more research. A consensus is lacking about several important issues surrounding competency, of which a clear definition of competency. This concept evolves over time; it is defined in the current concept analysis as the ability to execute assigned tasks or actions with the knowledge and skills needed to deliver safe, effective and quality care to individuals. This definition is consistent with the ICN and the ‘holism’ view of competency.

Concept analysis is a useful tool for conducting research in nursing. The outcome of this concept analysis would set the defining characteristics of ‘competency in nursing practice’, which will give the direction of what counts in clinical practice. Moreover, the attributes of competency in nursing practice are applying skills in all aspects of
the nursing practice. These characteristics and attributes would bring safe and high-quality nursing practice. The definitions, uses, attributes, antecedents and consequences of ‘competency in nursing practice’ were identified. This concept analysis provided further interpretation and specificity to the meaning of competency in nursing practice. The defining attributes of competency in nursing practice were knowledge, self-assessment and dynamic state. The antecedents of competency in nursing practice were education, knowledge, skills and abilities, standards of actions or behaviours, positive attitudes and responsibility for applying the knowledge. Other global antecedents included certain work environments and professional-related and sociodemographic variables. On the global level, 11 components of nursing competency were also identified. The common consequences of competency in nursing practice were decreased serious medical errors, patient safety, improved patient outcomes and nurses’ decision-making, self-assessment and accountability. Most existing tools were developed to assess competency in nursing practice from professionals’ perspectives; thus, new tools are required to measure competency in nursing practice from patients’ and healthcare administrators’ perspectives.

Acknowledgements The researchers would like to acknowledge the input of all research papers included in this study.

Contributors MTM and HYA conceptualised the study, developed literature review, wrote the first draft of the methodology and discussion, and developed the study’s protocol and the summary table of the included studies. AAK wrote the abstract and the significance, synthesised the literature review, and wrote the integrated draft of the methodology and the implications. MJR developed and synthesised concept analysis cases of nursing practice competency and did the critical revisions accordingly. AAK and SA-R did the critical revisions for the whole study, synthesised the whole parts and proofread the first draft of the paper. MTM and AAK wrote the final draft of the paper and supervised the whole work. HYA and AA proofread the final paper and did further syntheses, and HYA supervised the final stages of the paper after both reviews. AAS applied the method part of the concept analysis of competency in nursing. MTM and HYA accept full responsibility for the finished work and/or the conduct of the study as guarantors, had access to the data, and controlled the decision to publish.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient and public involvement Patients and/or the public were not involved in the design, conduct, or reporting, or dissemination plans of this research.

Patient consent for publication Not required.

Ethics approval This study does not involve human participants. As it is a concept analysis, it did not require the approval of an Institutional Review Board.

Provenance and peer review Not commissioned; externally peer reviewed.

Data availability statement All data relevant to the study are included in the article or uploaded as supplemental information.

Supplemental material This content has been supplied by the author(s). It has not been vetted by BMJ Publishing Group Limited (BMJ) and may not have been peer-reviewed. Any opinions or recommendations discussed are solely those of the author(s) and are not endorsed by BMJ. BMJ disclaims all liability and responsibility arising from any reliance placed on the content. Where the content includes any translated material, BMJ does not warrant the accuracy and reliability of the translations (including but not limited to local regulations, clinical guidelines, terminology, drug names and drug dosages), and is not responsible for any error and/or omissions arising from translation and adaptation or otherwise.
