Validation of a survey tool to assess the patient safety attitudes of pharmacy students

Abstract

Objective: Patient safety education is a key strategy to minimise this harm, and is increasingly being introduced into junior pharmacy curricula. However, currently there is no valid and reliable survey tool to measure the patient safety attitudes of pharmacy students. This study aimed to validate a modified survey tool, originally developed by Madigosky et al., to evaluate patient safety attitudes of junior pharmacy students.

Design: A 23 item cross-sectional patient safety survey tool was utilised to evaluate first and second year pharmacy students' attitudes during May 2013 with both exploratory and confirmatory factor analyses performed to understand the psychometric properties of the survey tool and to establish construct validity.

Setting: Undergraduate university students in Sydney, Australia

Participants: 245 first year and 201 second year students enrolled in the Bachelor of Pharmacy Program at The University of Sydney, Australia in May 2013.

Results: After exploratory factor analysis on first year student responses (55.76% variance explained) and confirmatory factor analysis on second year responses, a 5-factor model consisting of 14 items was obtained with satisfactory model fit ($\chi^2(66) = 112.83, p < .001, RMSEA = 0.06, CFI = 0.91$) and nesting between year groups ($\Delta\chi^2(7) = 3.079, p = 0.8780$). The 5 factors measured students' attitudes towards: (1) being quality improvement focused, (2) internalising errors regardless of harm, (3) value of contextual learning, (4) acceptability of questioning more senior healthcare professionals' behaviour and (5) attitude towards open disclosure.

Conclusion: This study has established the reliability and validity of a modified survey tool to evaluate patient safety attitudes of pharmacy students, with the potential for use in course development and evaluation.

Article Summary

Strengths and limitations of this study

- Patient safety is considered an essential part of pharmacist's vocational training however there is no validated tool published to measure pharmacy students' safety attitudes.
- This study validated a modified version of the most highly utilised survey tools to measure the patient safety attitudes of healthcare students in order to suit the requirements of junior pharmacy students.
- The large sample size obtained (N=446) allowed for a rigorous analytical approach to be undertaken, enabling both exploratory and confirmatory factor analyses to be performed with sufficient sample sizes for validation of the survey tool.
- The high response rates of students completing the survey (87.5% of first year students and 74.7% of second year students) means that the findings are likely to be representative of the attitudes of junior pharmacy students.
- Despite two of the factors consisting of only two items being a potential limitation of the short survey, the two items that loaded on these two factors adequately described the latent concepts being measured appropriate to the level of understanding and knowledge that junior pharmacy students have of the health care system.

Introduction

Patient safety has become a key priority for health systems around the world since the publication of the seminal reports *To Err is Human*[1] and *An Organisation with a Memory*[2] fifteen years ago. In 2002, World Health Organization (WHO) member states recognised the need to reduce the harm and suffering that patients and their families experience from healthcare errors, and agreed upon a resolution to improve patient safety. Education has since been considered a crucial element in minimising patient harm.[3] In 2011, the WHO published a multi-professional *Patient Safety Curriculum Guide*, derived from the Australian Patient Safety Education Framework, to assist healthcare schools to implement patient safety education.[4] However, the implementation of patient safety specific education can be challenging in already full university teaching curricula.[5]

Most pharmacy degree programs currently include education on some elements from the WHO curriculum including aspects related to medication safety, communication and patient centred care. It has been acknowledged that to improve the safety culture of healthcare organisations, students need to be able to recognise when they are working in unsafe conditions, how to manage working in unsafe conditions, be able to take a systems approach to the provision of healthcare, and to be able to manage errors and their causal factors, as well as the open disclosure of errors.[6,7] Considering that many students across healthcare disciplines, including pharmacy, are entering the health workforce at an earlier stage in their degrees, either through experiential placements or through casual employment, there is a greater need to instil patient safety knowledge from the commencement of their degrees and entry into the profession.[8,9]

In recognition of the increasing importance of patient safety education among pharmacy students, undergraduate students enrolled in the Bachelor of Pharmacy program at The University of Sydney, Australia, are now introduced to patient safety issues in the first year of their degree rather than in later years. There are a number of survey tools that measure patient safety attitudes and values of health care students, [6,10-15] with many of these tools based on the *Patient Safety/Medical Fallibility Survey* originally developed for medical students by Madigosky et al.[6] However, no survey tool has been validated to measure patient safety attitudes specifically among pharmacy students. Therefore, this study aimed to validate an adaptation of Madigosky et al.'s survey tool[6] in order to evaluate patient safety attitudes and values of junior pharmacy students, and specifically understand the psychometric properties that underpin the survey.

Methods

A cross-sectional survey was conducted among first (n=281) and second (n=269) year undergraduate pharmacy students enrolled in the four-year Bachelor of Pharmacy program at the University of Sydney. Data were collected between 27-31 May 2013, with approval to conduct this study granted by the Human Research Ethics Committee at the University of Sydney.

Survey

The survey tool was adapted from the *Patient Safety/Medical Fallibility Curriculum Survey* developed by Madigosky et al.[6] Specifically, survey items were modified to match first year Bachelor of Pharmacy students' level of knowledge and understanding of health care systems, resulting in the exclusion of skill and knowledge-based items from the original survey. The survey consisted of two sections: the first section contained the initial 22 attitudinal items of the *Patient Safety/Medical Fallibility Curriculum Survey*, as well as an attitudinal question to peer learning, and case studies to assess responses to scenarios; the second section collected demographic details including gender, age, stage of education, prior healthcare experience and involvement with an incident that resulted in harm or potential harm as a result of receiving healthcare.

A five-point Likert-type scale was used to measure student attitudes, with possible responses ranging from strongly disagree to strongly agree. The face validity of the survey instrument was assessed using a group of pharmacy students, academics and practising hospital and community pharmacists. Based on feedback from the group, definitions of "Patient Safety", "Error" and "Incident" as defined by the *Australian Commission for Safety and Quality in Healthcare* were included to assist students to complete the survey.

Analysis

All data analyses were completed using IBM SPSS Statistics version 21 (SPSS Inc., Chicago, IL) and AMOS version 21 (Amos Development Corporation, Crawfordville, FL). Participant characteristics were compared across year groups using Chi-square tests for categorical variables and Mann-Whitney and Kruskal-Wallis tests for continuous variables. In addition, the potential relationship between each of the participant demographic characteristics and their effects on survey responses were evaluated. A Bonferroni correction was applied to account for multiple comparisons, reducing the p-value for significance to 0.002.

1
2
3 An exploratory factor analysis (EFA) was performed on survey responses from the first year students
4 to understand the latent structure underpinning student responses to the survey using maximum
5 likelihood estimation and varimax rotation. As adequate sample sizes across both year groups were
6 obtained, Kaisers criterion for factor retention was adopted with individual factors loading greater
7 than 0.25 considered significant for retention.[16] The factor structure was assessed for a theoretical
8 basis, with an examination of the Scree plot used to verify the number of factors retained.
9
10
11

12
13
14 The construct validity of the survey was evaluated using a confirmatory factor analysis (CFA) on the
15 survey responses from the second year students. Each item was considered to have a latent
16 construct and a measurement error, with both causal effects depicted by uni-directional arrows.
17 Correlations between variables within the model were depicted using bi-directional arrows.[17]
18 Maximum likelihood estimation was performed to calculate item loading. Items were removed from
19 the model where there were: poor factor loading scores (being less than 0.25), insufficient number
20 of items loading on the construct, or an insufficient theoretical basis to the construct after item
21 removal.[16]
22
23
24
25
26
27
28

29 Boomsma's method of estimating a minimum sample size to conduct a CFA was performed based on
30 the number of items to number of factors ratio of the model; it was estimated that 200 student
31 responses would be adequate.[18] The goodness of fit of the model was evaluated using: Chi square
32 to measure model parsimony, root mean-square error of approximation (RMSEA) to measure
33 absolute fit, and the Comparative Fit Index (CFI) to evaluate the comparative fit.[19]

39 Results

40 Participant Characteristics

41 A total of 245 first-year and 201 second-year pharmacy students completed the survey, resulting in
42 survey response rates of 87.5% and 74.7%, respectively. The characteristics of the first and second
43 year students are compared in Table 1. There were very few differences in the characteristics
44 between the two groups of students, with the only significant difference being the number of
45 students engaged in current employment in a pharmacy (15.6% vs 44.4%, $p < 0.001$) and mean
46 months worked (2.4 vs 6.9, $p < 0.001$). However, as most students that are engaged in employment in
47 pharmacy are undertaking non-clinical roles (19.7% vs 8.6%), it is unlikely that current employment
48 will influence junior students' responses to the survey questions.

Table 1 – Participant characteristics

Characteristic	First year students (n=245)	Second year students (n=201)	P-value
Gender:			
Males, <i>n</i> (%)*	90 (36.9)	65 (32.8)	0.37
Females, <i>n</i> (%)*	154 (63.1)	132 (66.7)	
Age, in years, mean (SD)	19.4 (3.1)	20.0 (2.0)	<0.001
Students currently working in a pharmacy, <i>n</i> (%)*	38 (15.6)	88 (44.4)	<0.001
Months worked in pharmacy (mean, SD)	2.4 (9.5)	6.7 (11.9)	<0.001
Students who have been involved in or witnessed harm while working, <i>n</i> (%)*	21 (9.7)	29 (11.9)	0.06
Students who have witnessed harm to a loved one, <i>n</i> (%)*	35 (15.9)	35 (19.1)	0.14

*Note – percentages based on denominator of number of valid responses only

Comparisons of year group and other demographic characteristics with each of the survey items showed that demographic characteristics did not influence student responses after accounting for multiple comparisons with the Bonferroni correction (Appendix 1). However, two of the 23 attitudinal items which related to the inevitability of errors in healthcare and involving the patient in healthcare, showed statistical significance between year groups ($p=0.001$). Prior to the EFA, these items were removed as their exclusion was deemed not to have a significant impact on the model due to the inclusion of other survey items which measured similar concepts.

Exploratory Factor Analysis

Following the removal of 7 items, either due to low communalities (less than 0.2) or low factor loadings (less than 0.25) and examination of the Scree plot, a five factor solution was determined (Table 2). This solution explained 55.71% of the variance. Only one item cross-loaded and was assigned to a single factor based on theoretical reasoning. The five factors were labelled as being (1) quality improvement focused; (2) value of contextual learning; (3) internalising errors regardless of harm; (4) acceptability of questioning more senior healthcare professionals' behaviour and (5) attitude towards open disclosure of errors.

Q21	It is acceptable for a registered pharmacist to question the decisions of a prescriber (such as a doctor or nurse practitioner).					0.97	-
Q20	It is acceptable for an intern pharmacist to question the actions of a registered pharmacist.	0.34				0.36	-

3 **Confirmatory Factor Analysis**

4 In the second phase of the analysis, the construct validity of the instrument was established using
5 CFA. After mapping the responses from the second year students to the suggested model
6 determined by the EFA of first year students' responses, two items (Q5 and Q18) were removed due
7 to low factor loading (less than 0.25), resulting in the final factor structure (Table 3). The Chi-squared
8 values for overall model fit was significant, $\chi^2(69) = 134.23$, $p < 0.001$, which suggested a significant
9 misfit between the data and the model. However, it is known that in larger samples, the chi-squared
10 value can be over-sensitive and other fit indices were assessed (RMSEA = 0.07 CFI=0.88), which
11 suggested potential fit.[20] Modification indices suggested that freeing the covariance between two
12 error terms in factor 1, and one error term in factor 3, as well as between one error term in factor 2
13 and one error term in factor 3, would improve model fit. A model including these specified
14 correlations resulted in a subsequent model having better fit to the constrained model, $\chi^2(66) =$
15 112.83 , $p < 0.001$, RMSEA = 0.06, CFI = 0.91. Utilising data from both first year students and second
16 year students as part of a multi-group analysis, unconstrained nested model comparisons showed no
17 significant difference in the unconstrained model between year groups ($\Delta\chi^2(7) = 3.079, p=0.878$). This
18 indicates that both year groups satisfactorily fit the model. The combined data-set of first and
19 second year student responses (N=446) was used to calculate the final factor loadings as seen in
20 Figure 1.

3 284 29 **Discussion**

5 30 This study has validated a modified version of an existing patient safety attitudinal survey tool, the
6 31 *Patient Safety/Medical Fallibility Curriculum survey*,^[6] in pharmacy students. Given that the
7 32 literature identifies a significant need to provide more training to pharmacy and other healthcare
8 33 students on all aspects of patient safety, the use of this survey tool is crucial for evaluating the
9 34 impact of these programs.^[21-24] It is noteworthy that current patient safety programs for
10 35 pharmacy students often include elements of identifying, understanding, reporting, managing and
11 36 communicating risk. The underlying attitudes leading to the practice of these positive safety
12 37 behaviours can all be evaluated using the survey tool.

13
14
15
16
17
18
19
20
21
22
23

24 39 A robust two-staged analytical method, involving EFA followed by CFA, was used to assess the
25 40 reliability and validity of the survey tool. The results of these analyses demonstrated that the
26 41 attitudes which underpin students' responses could be explained by five underlying dimensions: (1)
27 42 being quality improvement focused, (2) internalising errors regardless of harm, (3) value of
28 43 contextual learning, (4) acceptability of questioning more senior healthcare professionals' behaviour
29 44 and (5) attitude towards open disclosure of errors. Four of these dimensions related to patient
30 45 safety attitudes (Factors 1, 2, 4 & 5) and one pertained to the delivery of patient safety interventions
31 46 (Factor 3). This survey tool can therefore be used to help assess the educational needs of students
32 47 and evaluate patient safety educational interventions.^[24]

33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 49 The first factor pertained to willingness to undertake quality improvement activities. The EFA on first
50 50 year students' responses revealed a relatively low internal consistency reliability for this factor
51 51 (Cronbach alpha =0.422). Two items (Q5 – Patients have a role to play in their own safety and Q18 –
52 52 After an error occurs, an effective strategy is to work hard to be more careful) had a relatively low
53 53 loading on the factor and made little contribution to the meaning of the factor. After the removal of
54 54 these items during the CFA process, there was a significant improvement in the Cronbach alpha in
55 55 second year responses (0.654), thereby demonstrating improved internal consistency. This factor
56 56 examined a positive attitude towards patient safety. Specifically this factor, focused on quality
57 57 improvement as an indicator of positive safety culture, with higher scores indicating a greater
58 58 emphasis towards taking a systems approach to dealing with errors, a desired outcome of many
59 59 patient safety programs.^[25] The second factor, however, measured a negative attitude toward
60 60 patient safety. This factor related to managing and reporting risk, whereby students internalise the
61 61 error rather than take action, regardless of whether the patient suffered harm. Thus higher scores

1
2
3 62 indicate that students may be less likely to appropriately manage an error. Scores on these factors
4 63 are important given that there is a push towards teaching incident reporting from junior years to
5 64 foster good behaviours and to develop a culture of understanding and preventing errors.[26]
6 65 Consequently, as students become more quality improvement focused (as measured by factor 1), it
7 66 would be expected that they would be more likely to appropriately manage an error rather than
8 67 internalising the issue (resulting in a corresponding decrease in scores on factor 2).[27]
9
10
11
12
13

14 69 The fourth factor measured how acceptable it is to students to question the decisions of more senior
15 70 healthcare professionals, an important part of managing risk in healthcare. Whilst the two items in
16 71 this scale are clearly related, these two items do differ significantly. The first item in the factor
17 72 relates to questioning the decision of a prescriber, whilst the second item relates to the questioning
18 73 of an action of a more senior pharmacist. Previous studies have identified that a major obstacle to
19 74 good patient safety practices among students is the hierarchical structure of healthcare
20 75 organisations, including community pharmacies where most pharmacy students obtain their first
21 76 clinical experience.[7,28] Being able to work well within teams has been associated with reduced
22 77 medical errors and improved outcomes in primary healthcare.[29-31] In addition to effective
23 78 communication, being able to deal with conflict, particularly with more senior healthcare
24 79 practitioners, is also considered an important skill.[32] Many patient safety education programs now
25 80 include training in managing situations resulting in conflict, and whilst this factor may not be able to
26 81 directly examine this skill, by measuring students' attitudes, it indirectly evaluates whether there is a
27 82 need for further training in this area.
28
29
30
31
32
33
34
35
36
37

38 84 A core element of all patient safety programs is the concept of patient-centred care, which includes
39 85 involving the patient in decisions about their own care and openly disclosing incidents when they
40 86 occur. Factor five related to open disclosure of errors and hence may be used as a measure of
41 87 students' willingness to openly disclose errors to patients, regardless of whether or not harm occurs.
42 88 Despite being uncommon in practice, open disclosure of errors by health care practitioners is
43 89 desired by patients and required by healthcare authorities.[33] Furthermore, it has been shown that
44 90 it is important for educators to commence open disclosure training as early as possible in order to
45 91 have the greatest impact on changing this behaviour.[34]
46
47
48
49
50
51
52

53 93 The final factor (Factor 3) related to the educational delivery of patient safety interventions. It
54 94 focused on the pedagogical method that would be most effective in delivering patient safety
55 95 education to junior pharmacy students[24] with items relating to the didactic method of teaching
56
57
58
59
60

1
2
3 96 patient safety through university lectures, and learning from experience in the workplace. It is
4 97 known that the learning preferences of students change throughout their degree, with more
5 98 meaning-directed approaches preferred as they progress through their degree.[35] This factor may
6 99 therefore be useful to guide the development of teaching materials, tailored to better suit students'
7
8
9
10 100 learning style preferences.

11
12 101
13 102 Despite the survey being used previously in evaluating patient safety attitudes of both medical and
14 103 nursing students, only one study has investigated the psychometric properties of the original
15 104 survey.[12] Schnall et al.[12] utilised 17 of the skill and attitudinal items from the original survey to
16 105 identify a nine item, three factor solution: "Error detection, time investment and creating a culture
17 106 of safety". Five of the nine items included in Schnall's factor analysis were also included in our final
18 107 CFA model, however, were placed under different factors in our analysis. Like Schnall et al., the
19 108 present study observed low reliability scores in our factors during the EFA with first year students.
20 109 However, when applying the EFA factor structure to our second year students, reliability scores
21 110 increased, which indicates that students may understand and relate to survey items better the
22 111 further they have progressed in their degrees as a result of receiving more practice-specific
23 112 education.

24 113
25 114 *Strengths and Limitations*

26 115 This study has a number of strengths. Firstly, in the absence of a published survey tool to evaluate
27 116 the patient safety attitudes of pharmacy students, this study modified one of the most highly utilised
28 117 survey tools to measure the patient safety attitudes of healthcare students[6 10 12] in order to suit
29 118 the requirements of junior pharmacy students. Furthermore, the relatively large sample size
30 119 obtained (N=446) allowed for a rigorous analytical approach to be undertaken, enabling both EFA
31 120 and CFA to be performed with sufficient sample sizes for validation of the survey tool. In addition,
32 121 the high response rates of students completing the survey (87.5% of first year students and 74.7% of
33 122 second year students) means that the findings are likely to be representative of the attitudes of
34 123 junior pharmacy students undertaking the Bachelor of Pharmacy program at the University of
35 124 Sydney. However, as the sample was drawn exclusively from a single institution, the findings may
36 125 not be representative of students enrolled in other pharmacy programs. Finally, two of the factors
37 126 (factor 4-questioning behaviours and factor 5-open disclosure) consisted of only two items. While
38 127 this is considered acceptable,[36] it is also a potential limitation that is likely a consequence of the
39 128 relatively short survey tool utilised. However, the two items that loaded on these two factors

1
2
3 129 adequately described the latent concepts being measured, and are appropriate to the level of
4 130 understanding and knowledge that junior pharmacy students have of the health care system.
5
6 131

8 132 **Conclusion**

9 133 This study has demonstrated the validity of a tool to evaluate the attitudes of pharmacy students
10 134 across a number of patient safety areas. Given that there is growing recognition of the need to
11 135 educate pharmacy students in patient safety concepts; this survey can be used by pharmacy schools
12 136 to evaluate the underlying dimensions of patient safety practices in order to tailor patient safety
13 137 training to better suit students' educational needs.

Validation of a survey tool to assess the patient safety attitudes of pharmacy students

Appendix 1 – Factors that may affect students' responses

Question Number	Item	Effect of demographic detail on survey response (P – Value)*						
		Year Group	Gender	Age	Prior health experience	Current Pharmacy Employment	Witnessed harm at work	Witnessed harm to a loved one
Q1	Errors in healthcare are inevitable.	0.001	0.455	0.827	0.189	0.284	0.208	0.148
Q2	Competent health care professionals do not make errors that lead to patient harm.	0.765	0.232	0.861	0.167	0.686	0.113	0.601
Q3	Pharmacists should routinely spend part of their professional time working to improve patient care.	0.830	0.891	0.493	0.548	0.506	0.336	0.931
Q4	Only medical practitioners can determine the causes of a medical error.	0.215	0.437	0.253	0.090	0.188	0.091	0.087
Q5	Patients have a role to play in their own safety.	0.001	0.896	0.318	0.747	0.140	0.132	0.916
Q6	The culture of the pharmacy workplace makes it easy for pharmacy staff to deal constructively with errors.	0.578	0.450	0.584	0.302	0.398	0.620	0.855
Q7	Learning how to improve patient safety is an appropriate use of time in pharmacy programs at university.	0.664	0.221	0.051	0.926	0.378	0.168	0.169
Q8	Healthcare professionals, including pharmacy staff, routinely	0.794	0.662	0.097	0.428	0.723	0.208	0.747

	share information about errors and what caused them.							
Q9	In my experience, faculty and staff communicate to me that patient safety is a high priority.	0.807	0.900	0.478	0.249	0.782	0.273	0.290
Q10	Pharmacists should report errors to an affected patient and their family if harm to the patient has occurred.	0.135	0.280	0.394	0.098	0.624	0.573	0.083
Q11	Pharmacists should discuss and report errors to an affected patient and their family even if the patient is <u>NOT</u> harmed.	0.048	0.340	0.330	0.223	0.598	0.674	0.685
Q12	Effective responses to errors in the delivery of healthcare focus primarily on the healthcare professional involved	0.014	0.897	0.122	0.335	0.751	0.060	0.095
Q13	Disciplinary action against an individual who made an error is an effective method of preventing future errors.	0.762	0.612	0.777	0.921	0.423	0.723	0.855
Q14	If there is no harm to a patient, there is no need to address an error.	0.917	0.961	0.057	0.210	0.537	0.884	0.264
Q15	If I saw an error that <u>DID</u> cause harm, I would keep it to myself.	0.799	0.341	0.283	0.659	0.127	0.056	0.253
Q16	If I saw an error that <u>DID NOT</u> cause harm, I would keep it to myself.	0.416	0.678	0.232	0.038	0.237	0.555	0.989
Q17	Most errors are due to things that healthcare professionals can't do anything about.	0.423	0.499	0.260	0.925	0.472	0.727	0.128
Q18	After an error occurs, an effective strategy is to work hard to be	0.091	0.087	0.154	0.297	0.410	0.635	0.125

	more careful.							
Q19	The care that we provide on a day to day basis could be improved.	0.249	0.562	0.116	0.331	0.038	0.125	0.109
Q20	It is acceptable for an intern pharmacist to question the actions of a registered pharmacist.	0.183	0.0.34	0.471	0.207	0.983	0.849	0.473
Q21	It is acceptable for a registered pharmacist to question the decisions of a prescriber (such as a doctor or nurse practitioner).	0.864	0.276	0.856	0.491	0.477	0.252	0.703

Validation of a survey tool to assess the patient safety attitudes of pharmacy students

Abstract

Objective: Patient safety education is a key strategy to minimise this harm, and is increasingly being introduced into junior pharmacy curricula. However, currently there is no valid and reliable survey tool to measure the patient safety attitudes of pharmacy students. This study aimed to validate a modified survey tool, originally developed by Madigosky et al., to evaluate patient safety attitudes of junior pharmacy students.

Design: A 23 item cross-sectional patient safety survey tool was utilised to evaluate first and second year pharmacy students' attitudes during May 2013 with both exploratory and confirmatory factor analyses performed to understand the psychometric properties of the survey tool and to establish construct validity.

Setting: Undergraduate university students in Sydney, Australia

Participants: 245 first year and 201 second year students enrolled in the Bachelor of Pharmacy Program at The University of Sydney, Australia in May 2013.

Results: After exploratory factor analysis on first year student responses (55.76% variance explained) and confirmatory factor analysis on second year responses, a 5-factor model consisting of 14 items was obtained with satisfactory model fit ($\chi^2(66) = 112.83, p < .001, RMSEA = 0.06, CFI = 0.91$) and nesting between year groups ($\Delta\chi^2(7) = 3.079, p = 0.8780$). The 5 factors measured students' attitudes towards: (1) being quality improvement focused, (2) internalising errors regardless of harm, (3) value of contextual learning, (4) acceptability of questioning more senior healthcare professionals' behaviour and (5) attitude towards open disclosure.

Conclusion: This study has established the reliability and validity of a modified survey tool to evaluate patient safety attitudes of pharmacy students, with the potential for use in course development and evaluation.

Keywords (MeSH): Patient safety; education; pharmacy ; attitude; questionnaire

Introduction

Patient safety has become a key priority for health systems around the world since the publication of the seminal reports *To Err is Human*[1] and *An Organisation with a Memory*[2] fifteen years ago. In 2002, World Health Organization (WHO) member states recognised the need to reduce the harm and suffering that patients and their families experience from healthcare errors, and agreed upon a resolution to improve patient safety. Education has since been considered a crucial element in minimising patient harm.[3] In 2011, the WHO published a multi-professional *Patient Safety Curriculum Guide* to assist healthcare schools to implement patient safety education.[4] However, the implementation of patient safety specific education can be challenging in already full university teaching curricula.[5]

Most pharmacy degree programs currently include education on some elements from the WHO curriculum, including aspects related to medication safety, communication and patient centred care.[6] Many students now gain work experience in healthcare settings at an earlier stage of their degrees, either through experiential placements or through casual employment, and therefore, there is a greater emphasis on the need to integrate patient safety education earlier on in professional degree programs.[7,8] In response to this, many pharmacy schools now incorporate patient safety education earlier in the curriculum.[9,10] Although evaluating patient safety knowledge is a key consideration when undertaking curriculum evaluation, it is also crucial that patient safety attitudes are understood and evaluated. This is particularly important in light of evidence that attitudes can considerably influence behaviours.[11]

There are a number of survey tools that have been used to measure patient safety attitudes and values of health care students, each to varying degrees.[9,10,12-19] The most widely adapted and validated tool is the Patient Safety/Medical Fallibility Survey, originally developed by Madigosky et al. for use in medical students.[12] Previous studies among pharmacy students have focused on evaluating patient safety knowledge and practice beliefs using unvalidated survey tools,[9,10] and attitudes to patient safety have been largely unstudied. Therefore, the aim of this study was to validate an adaptation of Madigosky et al.'s survey tool[12] in order to evaluate patient safety attitudes and values of junior pharmacy students, and specifically understand the psychometric properties that underpin the survey.

Methods

A cross-sectional survey was conducted among first (n=281) and second (n=269) year undergraduate pharmacy students enrolled in the four-year Bachelor of Pharmacy program at the University of Sydney. As both year groups would have completed an introductory pharmacy practice unit of study and introductory clinical placements (four hours) at the time of survey completion, it was hypothesised that these two groups of students would have the most comparable clinical experience and be suitable participants in the validation of the survey instrument. Data were collected between 27-31 May 2013, with approval to conduct this study granted by the Human Research Ethics Committee at the University of Sydney (project number 2013/219).

Survey

Survey Modification

The survey tool was adapted from the *Patient Safety/Medical Fallibility Curriculum Survey* developed by Madigosky et al.[12] Specifically, the original survey items that were included, suited first year Bachelor of Pharmacy students' level of knowledge and understanding of health care systems, which resulted in the exclusion of skill and knowledge-based items from the original survey. The survey consisted of two sections. The first section consisted of 23 attitudinal items, and included 17 of the original 18 attitudinal items and utilised the original five-point Likert-type scale to measure student attitudes, with possible responses ranging from strongly disagree to strongly agree. As the survey was being modified for pharmacy students, the use of the term "physician" was changed to "pharmacist" or "medical practitioner" based on the item. Items that related to the reporting of errors were split into two questions to evaluate whether students' responses would change due to the presence or absence of patient harm. In addition, two questions to evaluate attitudes towards questioning more senior health care professionals, one question on patients' role in healthcare and one question on peer learning were added. The second section collected demographic details including gender, age, stage of education, prior healthcare experience and involvement with an incident that resulted in harm or potential harm as a result of receiving healthcare.

Face validation

The face validity of the survey instrument was assessed through focus groups among three populations: initially among 5 pharmacy academics, 5 practising pharmacists and 7 pharmacy student representatives. Based on feedback from the three groups, one of the original questions relating to uncertainty in healthcare was considered ambiguous and was removed from the final survey tool. Pharmacy academics also perceived that due to junior pharmacy students' limited

1
2
3 clinical experience, definitions of “Patient Safety”, “Error” and “Incident” should be included in the
4 pretext to the survey. The student group were provided with terms defined by a range of healthcare
5 organisations. As a result, the definitions used by the *Australian Commission for Safety and Quality*
6 *in Healthcare* were selected due to both the perceived ease of understanding and perceived
7 contextual relevance to junior pharmacy students. The final survey was approved by each group in a
8 subsequent focus group.
9
10
11

12 13 14 **Analysis**

15 All data analyses were completed using IBM SPSS Statistics version 21 (SPSS Inc., Chicago, IL) and
16 AMOS version 21 (Amos Development Corporation, Crawfordville, FL). Surveys with missing data
17 were excluded from the analysis. The survey response rate was calculated by dividing the total
18 number of surveys completed by the number of students enrolled in each year group. Participant
19 characteristics were compared across year groups using Chi-square tests for categorical variables
20 and Mann-Whitney and Kruskal-Wallis tests for continuous variables. In addition, the potential
21 relationship between each of the participant demographic characteristics and their effects on survey
22 responses were evaluated. A Bonferroni correction was applied to account for multiple comparisons,
23 reducing the p-value for significance to 0.002.
24
25
26
27
28
29
30
31

32 An exploratory factor analysis (EFA) was performed on survey responses from the first year students
33 to understand the latent structure underpinning student responses to the survey using maximum
34 likelihood estimation and varimax rotation. As adequate sample sizes across both year groups were
35 obtained, Kaisers criterion for factor retention was adopted with individual factors loading greater
36 than 0.25 considered significant for retention.[20] The factor structure was assessed for a theoretical
37 basis, with an examination of the Scree plot used to verify the number of factors retained.
38
39
40
41
42

43 The construct validity of the survey was evaluated using a confirmatory factor analysis (CFA) on the
44 survey responses from the second year students. Each item was considered to have a latent
45 construct and a measurement error, with both causal effects depicted by uni-directional arrows.
46 Correlations between variables within the model were depicted using bi-directional arrows.[21]
47 Maximum likelihood estimation was performed to calculate item loading. Items were removed from
48 the model where there were: poor factor loading scores (being less than 0.25), insufficient number
49 of items loading on the construct, or an insufficient theoretical basis to the construct after item
50 removal.[20]

53
54
55
56
57
58
59
60

1
2
3 Boomsma's method of estimating a minimum sample size to conduct a CFA was performed based on
4 the number of items to number of factors ratio of the model; it was estimated that 200 student
5 responses would be adequate.[22] To evaluate the goodness of fit of the model, a number of fit
6 statistics were examined. Firstly, the Chi Square statistic was used to evaluate model parsimony (i.e.
7 that the model accomplishes a desired level of explanation with as few variables and relationships
8 between variables as possible). In addition, root mean-square error of approximation (RMSEA) was
9 used to evaluate absolute fit (a measure of how well the data sits the proposed model) and the
10 Comparative Fit Index (CFI) was used to evaluate the comparative fit (a measure of how well the
11 data fits a model where relationships exist between the survey items compared to a model where no
12 relationships exist).[23,24]

Results

Participant Characteristics

A total of 245 first-year and 201 second-year pharmacy students completed the survey, resulting in survey response rates of 87.5% and 74.7%, respectively. The characteristics of the first and second year students are compared in Table 1. There were very few differences in the characteristics between the two groups of students, with the only significant difference being the number of students engaged in current employment in a pharmacy (15.6% vs 44.4%, $p < 0.001$) and mean months worked (2.4 vs 6.9, $p < 0.001$). However, as most students that are engaged in employment in pharmacy are undertaking non-clinical roles (19.7% vs 8.6%), it is unlikely that current employment will influence junior students' responses to the survey questions.

Table 1 – Participant characteristics

Characteristic	First year students (n=245)	Second year students (n=201)	P-value
Gender:			
Males, <i>n</i> (%)*	90 (36.9)	65 (32.8)	0.37
Females, <i>n</i> (%)*	154 (63.1)	132 (66.7)	
Age, in years, mean (SD)	19.4 (3.1)	20.0 (2.0)	<0.001
Students currently working in a pharmacy, <i>n</i> (%)*	38 (15.6)	88 (44.4)	<0.001
Months worked in pharmacy (mean, SD)	2.4 (9.5)	6.7 (11.9)	<0.001
Students who have been involved in or witnessed harm while working, <i>n</i> (%)*	21 (9.7)	29 (11.9)	0.06
Students who have witnessed harm to a loved one, <i>n</i> (%)*	35 (15.9)	35 (19.1)	0.14

*Note – percentages based on denominator of number of valid responses only

Comparisons of year group and other demographic characteristics with each of the survey items showed that demographic characteristics did not influence student responses after accounting for multiple comparisons with the Bonferroni correction (Appendix 1). However, two of the 23 attitudinal items which related to the inevitability of errors in healthcare and involving the patient in healthcare, showed statistical significance between year groups ($p = 0.001$). Prior to the EFA, these

1
2
3 items were removed as their exclusion was deemed not to have a significant impact on the model
4 due to the inclusion of other survey items which measured similar concepts.
5
6

7 8 **Exploratory Factor Analysis**

9
10 Following the removal of 7 items, either due to low communalities (less than 0.2) or low factor
11 loadings (less than 0.25) and examination of the Scree plot, a five factor solution was
12 determined (Table 2). This solution explained 55.71% of the variance. Only one item cross-loaded and
13 was assigned to a single factor based on theoretical reasoning. The five factors were labelled as
14 being (1) quality improvement focused; (2) value of contextual learning; (3) internalising errors
15 regardless of harm; (4) acceptability of questioning more senior healthcare professionals' behaviour
16 and (5) attitude towards open disclosure of errors.

Peer review only

3 Confirmatory Factor Analysis

4 In the second phase of the analysis, the construct validity of the instrument was established using
5 CFA. After mapping the responses from the second year students to the suggested model
6 determined by the EFA of first year students' responses, two items (Q5 and Q18) were removed due
7 to low factor loading (less than 0.25), resulting in the final factor structure (Table 3). The Chi-squared
8 values for overall model fit was significant, $\chi^2(69) = 134.23$, $p < 0.001$, which suggested a significant
9 misfit between the data and the model. However, it is known that in larger samples, the chi-squared
10 value can be over-sensitive and other fit indices were assessed (RMSEA = 0.07 CFI=0.88), which
11 suggested potential fit.[25] Modification indices suggested that freeing the covariance between two
12 error terms in factor 1, and one error term in factor 3, as well as between one error term in factor 2
13 and one error term in factor 3, would improve model fit. A model including these specified
14 correlations resulted in a subsequent model having better fit to the constrained model, $\chi^2(66) =$
15 112.83 , $p < 0.001$, RMSEA = 0.06, CFI = 0.91. Utilising data from both first year students and second
16 year students as part of a multi-group analysis, unconstrained nested model comparisons showed no
17 significant difference in the unconstrained model between year groups ($\Delta\chi^2(7) = 3.079$, $p = 0.878$). This
18 indicates that both year groups satisfactorily fit the model. The combined data-set of first and
19 second year student responses (N=446) was used to calculate the final factor loadings as seen in
20 Figure 1.

28 Discussion

29 This study has validated a modified version of an existing patient safety attitudinal survey tool, the
30 *Patient Safety/Medical Fallibility Curriculum survey*,^[12] in pharmacy students. A robust two-staged
31 analytical method, involving EFA followed by CFA, was used to assess the reliability and validity of
32 the survey tool. The results of these analyses demonstrated that the attitudes which underpin
33 students' responses could be explained by five underlying dimensions: (1) being quality
34 improvement focused, (2) internalising errors regardless of harm, (3) value of contextual learning,
35 (4) acceptability of questioning more senior healthcare professionals' behaviour and (5) attitude
36 towards open disclosure of errors. Four of these dimensions related to patient safety attitudes
37 (Factors 1, 2, 4 & 5) and one pertained to the delivery of patient safety interventions (Factor 3). This
38 survey tool can therefore be used to help assess the educational needs of students and evaluate
39 patient safety educational interventions.^[26]

40
41 The first factor pertained to willingness to undertake quality improvement activities. The EFA on first
42 year students' responses revealed a relatively low internal consistency reliability for this factor
43 (Cronbach alpha =0.422). Two items (Q5 – Patients have a role to play in their own safety and Q18 –
44 After an error occurs, an effective strategy is to work hard to be more careful) had a relatively low
45 loading on the factor and made little contribution to the meaning of the factor. After the removal of
46 these items during the CFA process, there was a significant improvement in the Cronbach alpha in
47 second year responses (0.654), thereby demonstrating improved internal consistency. This factor
48 examined a positive attitude towards patient safety. Specifically this factor, focused on quality
49 improvement as an indicator of positive safety culture, with higher scores indicating a greater
50 emphasis towards taking a systems approach to dealing with errors, a desired outcome of many
51 patient safety programs.^[27] The second factor, however, measured a negative attitude toward
52 patient safety. This factor related to managing and reporting risk, whereby students internalise the
53 error rather than take action, regardless of whether the patient suffered harm. Thus higher scores
54 indicate that students may be less likely to appropriately manage an error. Scores on these factors
55 are important given that there is a push towards teaching incident reporting from junior years to
56 foster good behaviours and to develop a culture of understanding and preventing errors.^[28]
57 Consequently, as students become more quality improvement focused (as measured by factor 1), it
58 would be expected that they would be more likely to appropriately manage an error rather than
59 internalising the issue (resulting in a corresponding decrease in scores on factor 2).^[29]

60

1
2
3 61 The fourth factor measured how acceptable it is to students to question the decisions of more senior
4 62 healthcare professionals, an important part of managing risk in healthcare. Whilst the two items in
5 63 this scale are clearly related, these two items do differ significantly. The first item in the factor
6 64 relates to questioning the decision of a prescriber, whilst the second item relates to the questioning
7 65 of an action of a more senior pharmacist. Previous studies have identified that a major obstacle to
8 66 good patient safety practices among students is the hierarchical structure of healthcare
9 67 organisations, including community pharmacies where most pharmacy students obtain their first
10 68 clinical experience.[30,31] Being able to work well within teams has been associated with reduced
11 69 medical errors and improved outcomes in primary healthcare.[32-34] In addition to effective
12 70 communication, being able to deal with conflict, particularly with more senior healthcare
13 71 practitioners, is also considered an important skill.[35] Many patient safety education programs now
14 72 include training in managing situations resulting in conflict, and whilst this factor may not be able to
15 73 directly examine this skill, by measuring students' attitudes, it indirectly evaluates whether there is a
16 74 need for further training in this area.
17
18
19
20
21
22
23
24
25
26

27 76 A core element of all patient safety programs is the concept of patient-centred care, which includes
28 77 involving the patient in decisions about their own care and openly disclosing incidents when they
29 78 occur. Factor five related to open disclosure of errors and hence may be used as a measure of
30 79 students' willingness to openly disclose errors to patients, regardless of whether or not harm occurs.
31 80 Despite being uncommon in practice, open disclosure of errors by health care practitioners is
32 81 desired by patients and required by healthcare authorities.[36] Furthermore, it has been shown that
33 82 it is important for educators to commence open disclosure training as early as possible in order to
34 83 have the greatest impact on changing this behaviour.[37]
35
36
37
38
39
40
41

42 85 The final factor (Factor 3) related to the educational delivery of patient safety interventions. It
43 86 focused on the pedagogical method that would be most effective in delivering patient safety
44 87 education to junior pharmacy students[26] with items relating to the didactic method of teaching
45 88 patient safety through university lectures, and learning from experience in the workplace. It is
46 89 known that the learning preferences of students change throughout their degree, with more
47 90 meaning-directed approaches preferred as they progress through their degree.[38] This factor may
48 91 therefore be useful to guide the development of teaching materials, tailored to better suit students'
49 92 learning style preferences.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 94 Despite the survey being used previously in evaluating patient safety attitudes of both medical and
4 95 nursing students, only one study has investigated the psychometric properties of the original
5 96 survey.[15] Schnall et al.[15] utilised 17 of the skill and attitudinal items from the original survey to
6 97 identify a nine item, three factor solution: "Error detection, time investment and creating a culture
7 98 of safety". Five of the nine items included in Schnall's factor analysis were also included in our final
8 99 CFA model, however, were placed under different factors in our analysis. Like Schnall et al., the
9 100 present study observed low reliability scores in our factors during the EFA with first year students.
10 101 However, when applying the EFA factor structure to our second year students, reliability scores
11 102 increased, which indicates that students may understand and relate to survey items better the
12 103 further they have progressed in their degrees as a result of receiving more practice-specific
13 104 education.

105

106 **Implications for Educators**

107 The use of this survey tool provides a number of benefits for educators. Given that the literature
108 identifies a significant need to provide more training to pharmacy and other healthcare students on
109 all aspects of patient safety, it is crucial that pharmacy schools have a mechanism for evaluating the
110 impact of these programs.[26,39-41] It is noteworthy that current patient safety programs for
111 pharmacy students often include elements of identifying, understanding, reporting, managing and
112 communicating risk. The underlying attitudes leading to the practice of these positive safety
113 behaviours can all be evaluated using the survey tool. In addition, there are a number of potential
114 benefits which may arise through the repeated use of this tool throughout a student's degree
115 program. Firstly, it will provide a means to evaluate the longitudinal effect of patient safety
116 education interventions and changes in students' attitudes. It can also be used to measure the effect
117 of the informal and hidden curricula on students' patient safety attitudes, which is particularly
118 important as students commence experiential learning placements and as more students engage in
119 casual employment in assistance roles. Thus the evaluation of these changes can provide useful
120 information about the educational needs of students through their degrees and when additional and
121 more targeted interventions will need to be provided.

122

123 **Strengths and Limitations**

124 This study has a number of strengths. Firstly, in the absence of a published survey tool to evaluate
125 the patient safety attitudes of pharmacy students, this study modified one of the most highly utilised
126 survey tools to measure the patient safety attitudes of healthcare students[12,13,15] in order to suit
127 the requirements of junior pharmacy students. Furthermore, the relatively large sample size

1
2
3 128 obtained (N=446) allowed for a rigorous analytical approach to be undertaken, enabling both EFA
4 129 and CFA to be performed with sufficient sample sizes for validation of the survey tool. In addition,
5 130 the high response rates of students completing the survey (87.5% of first year students and 74.7% of
6 131 second year students) means that the findings are likely to be representative of the attitudes of
7 132 junior pharmacy students undertaking the Bachelor of Pharmacy program at the University of
8 133 Sydney. However, as the sample was drawn exclusively from a single institution, the findings may
9 134 not be representative of students enrolled in other pharmacy programs. In addition, despite test-
10 135 retest reliability not being performed, conducting a CFA on data collected at the same time ensured
11 136 a form of reliability in the study. Finally, two of the factors (factor 4-questioning behaviours and
12 137 factor 5-open disclosure) consisted of only two items. While this is considered acceptable,[42] it is
13 138 also a potential limitation that is likely a consequence of the relatively short survey tool utilised.
14 139 However, the two items that loaded on these two factors adequately described the latent concepts
15 140 being measured, and are appropriate to the level of understanding and knowledge that junior
16 141 pharmacy students have of the health care system.

3 144 **Conclusion**

4 145 This study has demonstrated the validity of a tool to evaluate the attitudes of pharmacy students
5
6 146 across a number of patient safety areas. Given that there is growing recognition of the need to
7
8 147 educate pharmacy students in patient safety concepts, this survey can be used by pharmacy schools
9
10 148 to evaluate the underlying dimensions of students' patient safety attitudes, which have direct effects
11
12 149 on the manner in which students practice. Through the use of this tool, pharmacy schools will be
13
14 150 able to further develop and tailor their patient safety training to better suit students' educational
15
16 151 needs.

17 152
18 153 **Acknowledgements**

19 154 The authors would like to thank the Faculty of Pharmacy for supporting this project and the
20
21 155 undergraduate students who participated in this study.

22 156
23
24 157 **Funding**

25 158 This work was supported by the International Pharmaceutical Federation's (FIP) Young
26
27 159 Pharmacist/Pharmaceutical Scientist Grant for Professional Innovation 2012. FIP had no involvement
28
29 160 in the development, execution or evaluation of this study.

33 163 None

34 164
35
36
37 165 **Contributorship Statement**

38 166 RW conceived and designed the study, delivered peer educator training, collected and analysed the
39
40 167 data and drafted the manuscript. RF assisted in the design of the study, analysis of the results and
41
42 168 revised the manuscript. SC assisted in the analysis of the results and revised the manuscript. AM and
43
44 169 TC assisted in the design of the study and revised the manuscript.

45 170
46
47 171 **Data Sharing Statement**

48 172 No additional data are available

Validation of a survey tool to assess the patient safety attitudes of pharmacy students

Appendix 1 – Factors that may affect students' responses

Question Number	Item	Effect of demographic detail on survey response (P – Value)*						
		Year Group	Gender	Age	Prior health experience	Current Pharmacy Employment	Witnessed harm at work	Witnessed harm to a loved one
Q1	Errors in healthcare are inevitable.	0.001	0.455	0.827	0.189	0.284	0.208	0.148
Q2	Competent health care professionals do not make errors that lead to patient harm.	0.765	0.232	0.861	0.167	0.686	0.113	0.601
Q3	Pharmacists should routinely spend part of their professional time working to improve patient care.	0.830	0.891	0.493	0.548	0.506	0.336	0.931
Q4	Only medical practitioners can determine the causes of a medical error.	0.215	0.437	0.253	0.090	0.188	0.991	0.087
Q5	Patients have a role to play in their own safety.	0.001	0.896	0.318	0.747	0.140	0.332	0.916
Q6	The culture of the pharmacy workplace makes it easy for pharmacy staff to deal constructively with errors.	0.578	0.450	0.584	0.302	0.398	0.420	0.855
Q7	Learning how to improve patient safety is an appropriate use of time in pharmacy programs at university.	0.664	0.221	0.051	0.926	0.378	0.168	0.169
Q8	Healthcare professionals, including pharmacy staff, routinely	0.794	0.662	0.097	0.428	0.723	0.208	0.747

	share information about errors and what caused them.							
Q9	In my experience, faculty and staff communicate to me that patient safety is a high priority.	0.807	0.900	0.478	0.249	0.782	0.773	0.290
Q10	Pharmacists should report errors to an affected patient and their family if harm to the patient has occurred.	0.135	0.280	0.394	0.098	0.624	0.673	0.083
Q11	Pharmacists should discuss and report errors to an affected patient and their family even if the patient is <u>NOT</u> harmed.	0.048	0.340	0.330	0.223	0.598	0.674	0.685
Q12	Effective responses to errors in the delivery of healthcare focus primarily on the healthcare professional involved	0.014	0.897	0.122	0.335	0.751	0.660	0.095
Q13	Disciplinary action against an individual who made an error is an effective method of preventing future errors.	0.762	0.612	0.777	0.921	0.423	0.623	0.855
Q14	If there is no harm to a patient, there is no need to address an error.	0.917	0.961	0.057	0.210	0.537	0.684	0.264
Q15	If I saw an error that <u>DID</u> cause harm, I would keep it to myself.	0.799	0.341	0.283	0.659	0.127	0.656	0.253
Q16	If I saw an error that <u>DID NOT</u> cause harm, I would keep it to myself.	0.416	0.678	0.232	0.038	0.237	0.655	0.989
Q17	Most errors are due to things that healthcare professionals can't do anything about.	0.423	0.499	0.260	0.925	0.472	0.627	0.128
Q18	After an error occurs, an effective strategy is to work hard to be	0.091	0.087	0.154	0.297	0.410	0.635	0.125

36/bmjopen-2015-008442 on September 10, 2015. Downloaded from http://bmjopen.bmj.com/ on April 26, 2024 by guest. Protected by copyright.

	more careful.							
Q19	The care that we provide on a day to day basis could be improved.	0.249	0.562	0.116	0.331	0.038	0.125	0.109
Q20	It is acceptable for an intern pharmacist to question the actions of a registered pharmacist.	0.183	0.0.34	0.471	0.207	0.983	0.449	0.473
Q21	It is acceptable for a registered pharmacist to question the decisions of a prescriber (such as a doctor or nurse practitioner).	0.864	0.276	0.856	0.491	0.477	0.52	0.703
Q22	Patient safety education requires university lecturers to teach patient safety concepts.	0.879	0.528	0.358	0.245	0.604	0.21	0.056
Q23	Peer-led education, such as from pharmacist colleagues or fellow students can help my understanding of patient safety concepts.	0.603	0.441	0.450	0.563	0.269	0.98	0.247
