76

77 **Abstract**

78 Introduction: Developing countries are facing a remarkable increase in elderly population.

79 Demographic transition, along with rapid urbanization and changing family structures inevitably
80 expose older adults to risks of abuse. Despite being now recognized as a global health concern,
81 there is still inadequate amount of research into elder abuse and neglect especially in the low and
82 middle income region. The purpose of this paper is to report on the design and methodology of a
83 population-based cohort study on elder mistreatment among the older Malaysian population. The
84 study aims at gathering data and evidence to estimate the prevalence and incidence of elder
85 mistreatment, identify its individual, familial and social determinants, and quantify its health
86 consequences.

87 Methods: This is a community-based prospective cohort study using randomly selected
88 households from the national census. The study is divided into two phases; phase I: cross-
89 sectional study (baseline), and phase II: a longitudinal follow-up study. The study will employ a
90 multi-stage sampling method to obtain a total of 5000 subjects. Those who agree to participate

1
2
3 91 will be enrolled in a cross-sectional assessment and contacted at the 3rd and 5th years following
4
5 92 the initial data collection for subsequent follow-ups. Besides prevalence, incidence and risk
6
7
8 93 factors, outcomes of interest include mortality, physical function, mental health, quality of life
9
10 94 and health utilization. Statistical analysis will be done using the SPSS version 21.0 software
11
12 95 program. Logistic regression models are used to examine the relationship between exposure and
13
14 96 outcome variables.

15
16
17 97 Ethics and dissemination: The study has been approved by the Medical Ethics Committee of the
18
19 98 University of Malaya Medical Center and Malaysian National Medical Research Register.

20 99 Written consent was obtained from all respondents prior to baseline assessment. Findings will be
21
22 100 published in appropriate scientific journals and presented at local and international conferences.

32 103

33 34 104 **Strengths and limitations of this study**

35 36 105 Strengths

- 37
38
39 106 • Among the first few cohort studies looking into elder abuse and neglect in the region.
40
41 107 • Prospective study design with a long period of follow-up.
42
43 108 • Emphasis not only on epidemiological characteristics but also on determinants at
44
45 109 different levels of framework.
46
47
48 110 • Face-to-face interview, active engagement of local community and personalized contact
49
50 111 to ensure high response rate and minimize loss to follow up.
51
52 112 • Study subjects are representative of the rural Malaysian older population as the sampling
53
54 113 frame is derived from the national census.
55
56
57
58
59
60

114 Limitation

- 115 • This study focuses on older adults in the rural area, therefore generalizability of findings
116 to the urban older Malaysians can be an issue.

117

118

119

120 **INTRODUCTION**

121 The publication of “Granny Bashing” in 1975 is generally regarded as the starting point for the
122 systematic research into elder abuse (1, 2). More recently, there has been an expanding
123 movement to improve elderly’s rights and their physical and emotional well-being. The World
124 Health Organization has recognized elder mistreatment, also known as elder abuse and neglect
125 (EAN) as a growing challenge to the field of public health, social and criminal justice
126 worldwide. EAN is defined as ‘a single or repeated act, or lack of appropriate action, occurring
127 within any relationship where there is an expectation of trust which causes harm or distress to an
128 elder person’. This includes detriment to older adults by people they know or with whom they
129 have a relationship, such as the spouse, partner or family member, friend or neighbour, or those
130 on whom they rely for services (3). EAN is broadly categorized into physical, psychological or
131 emotional, financial, sexual and neglect (4).

132

133 Research findings in economically developed regions and circumstantial evidence suggest that
134 elder mistreatment is a much more universal phenomenon than what is generally perceived by
135 society. EAN prevalence estimates documented by recent studies varied from as low as 1.1% to

1
2
3 136 as high as 44.6% (5). Early studies of elder mistreatment derived from Western countries
4
5
6 137 indicated an association between abuse and gender, socioeconomic status, and ethnicity (6-8).
7
8 138 For instance, older women were more likely to experience mistreatment but this differed
9
10 139 according to the type of abuse (6). Older adults with cognitive and functional impairment,
11
12 140 dementia, disabilities and other chronic health problems are particularly at risk of abuse due to
13
14 141 increased dependence on caregivers (9-11). Caregivers' psychiatric disorders, previous history of
15
16 142 victimization, poor social support, substance use, high levels of hostility and their dependence on
17
18 143 the victim for accommodation and finance also appear to be associated with elder mistreatment
19
20 144 (10, 12-14). Others reported shared living arrangement, social isolation, loneliness and caregiver
21
22 145 strain as risk factors (12, 15).
23
24
25
26
27
28
29

30
31 147 The 'mapping' of elder mistreatment occurrences and understanding of its risk factors and
32
33 148 health consequences across cultures have been significantly limited by the narrow geographical
34
35 149 base of current research, with most being conducted in economically developed countries. This
36
37 150 distinct gap in the existing literature is reflected by the paucity of robust studies on EAN in low
38
39 151 and middle-income developing nations. The 'identified' risk factors may be less pertinent or not
40
41 152 fully applicable to the more conservative Asian cultures, considering the deeply ingrained
42
43 153 concepts of family ties and filial piety. Wu and colleagues (2014) found that many Chinese
44
45 154 viewed elder mistreatment as non-existent in their community owing to the traditional values and
46
47 155 cultural norms which emphasize respect of, and provision of care for parents by adult children.
48
49
50 156 On the contrary, their study findings showed that at least one-third of the interviewed older
51
52 157 adults reported experiencing some forms of mistreatment, suggesting the pervasiveness and
53
54 158 lack of awareness on EAN in the community (16). Hence, further research to determine the
55
56
57
58
59
60

1
2
3 159 extent of elder mistreatment and the universality of its risk factors across different populations is
4
5
6 160 necessary. Empirical data is essential to identify older adults at risk and facilitate the
7
8 161 development of community-specific and evidence-based preventive measures.
9

10 162
11
12 163 Malaysia is a multiethnic and multicultural country with a population estimate of 29 million in
13
14
15 164 2014. According to the World Bank classification, Malaysia is an upper-middle income and
16
17 165 developing economy situated in the East Asia and Pacific region (17). Its population consists of
18
19
20 166 mainly ethnic Malays (47%), followed by Chinese (25%), Indians (7%), and indigenous tribal
21
22 167 groups (11%). Population projections predict that the number of people aged 60 years and above
23
24 168 will form nearly 11 % of the national population by 2020, and this figure will double by 2040
25
26
27 169 (18). This substantial increase in older populace, along with rapid urbanization and changing
28
29 170 family structures will bring about greater challenges to the provision of care for the elderly. Like
30
31 171 many Asian countries, most older Malaysians rely heavily on their children for care and financial
32
33
34 172 support. This is especially customary among those living in rural areas where there is inadequate
35
36 173 pension and social support system and limited access to medical care, as compared to that
37
38 174 enjoyed by their more affluent urban counterparts. The rural-urban migration of youths in search
39
40
41 175 of better job opportunities has also greatly weakened the family's perceived obligation of caring
42
43 176 for their elder members. The lack of social safety net coupled with heavy reliance on their
44
45
46 177 children expose the rural older population to a greater likelihood of abuse and exploitation.
47

48 178
49
50 179 A number of countries have enacted statutes for reporting EAN and protection of the elderly.
51
52 180 There is no specific legislation to address EAN in Malaysia to date. The provision of the
53
54
55 181 Domestic Violence Act 1994 is relatively non-specific; it covers all family members including
56
57
58
59
60

1
2
3 182 older adults within a household (19, 20). Official or authenticated data on EAN is also
4
5 183 unavailable to gauge the true extent of the problem. While the Malaysian government has
6
7
8 184 demonstrated commitment to protect the rights and welfare of the elderly through a number of
9
10 185 initiatives, there remains little information from well-designed community based research into
11
12 186 the multiple dimensions of EAN. To address this need, the Malaysian Elder miSTreatment
13
14 187 pROject (MAESTRO) study was designed to estimate the prevalence and incidence of elder
15
16 188 mistreatment, describe the characteristics of perpetrators, identify individual, familial,
17
18 189 community and social determinants of EAN and assess its health consequences among a
19
20 190 representative sample of Malaysian older adults.
21
22
23
24
25 191

28 192 **Objective of the study and conceptual framework**

30
31 193 The overarching aims of the study are to estimate the prevalence and incidence of elder
32
33 194 mistreatment, its subtypes and multiple types of mistreatment; to identify the extent to which
34
35 195 elder mistreatment is predicted by individual, familial, community and social determinants, and;
36
37 196 to determine the consequences of EAN in relation to injuries, physical health and function,
38
39 197 mental health, health utilization and mortality.
40
41
42
43
44 198

45
46
47 199 This project employed a conceptual framework adapted and modified from the World Health
48
49 200 Organization. Applying the ecological approach, the framework guided the development of the
50
51 201 study design and selection of the range of potential determinants and outcomes of EAN. The
52
53 202 central thesis of this framework is the emphasis on the interaction and dynamics of multiple
54
55 203 determinants at various ecological levels in which victims and perpetrators are embedded;
56
57
58
59
60

1
2
3 204 individual, relationship, community and sociocultural. In this study, we examined both the risk
4
5 205 factors for, and protective factors against elder mistreatment, along with its outcomes. Figure 1
6
7
8 206 illustrated the conceptual framework of this study.
9

10
11 207 [insert Figure 1]
12
13
14 208

17 209 **METHODS AND ANALYSIS**

20 210 **Study design**

21
22
23 211 This is a 5-year prospective longitudinal cohort study among community dwelling older adults
24
25 212 aged 60 years and older and their caregivers, residing in the district of Kuala Pilah in the state of
26
27
28 213 Negeri Sembilan, Malaysia. It commenced in November 2013 and is currently ongoing. The
29
30 214 study will be executed in two phases. Phase I comprises a cross-sectional study and phase II is an
31
32
33 215 open cohort follow-up study across a 5-year period. Participants will be followed up at baseline,
34
35 216 3rd, and 5th year.
36
37

38 217

41 218 **Sample selection and Study participants**

42
43
44 219 A two-stage cluster sampling was employed to select study subjects. In the first stage, one
45
46 220 representative district, Kuala Pilah was randomly selected from seven districts available in the
47
48
49 221 state of Negeri Sembilan. Negeri Sembilan lies in the central of Peninsular Malaysia, about 100
50
51 222 kilometres away from the capital city, Kuala Lumpur. Its population stands at 1.02 million
52
53
54 223 according to the national census. Compared to other districts, Kuala Pilah has the biggest
55
56 224 population of older adults in the state. In the second stage, the Malaysian Department of
57
58
59
60

1
2
3 225 Statistics (DoS) provided a comprehensive sampling frame based on the most recent national
4
5 226 census conducted in 2010. Out of 254 enumeration blocks (EBs) within Kuala Pilah, 156 EBs
6
7
8 227 were randomly chosen. Each EB contained a minimum of 15% of older individuals. A
9
10 228 computer-generated list of households was then provided, from which 16-20 households were
11
12 229 randomly selected from every EB. Maps of the local terrain provided by the DoS were used to
13
14 230 locate selected households. The Malaysian Department of Statistics performs the national census
15
16 231 every ten years and retains the most comprehensive and up-to-date information on the population
17
18 232 demographics (18). This method of complex sampling design ensured adequate coverage of
19
20 233 older adults in all parts of the district, yielding a heterogeneous representative sample from the
21
22 234 target population.
23
24
25
26
27

28 235
29
30 236 Respondents were interviewed at home by trained personnel, using a structured questionnaire.
31
32 237 An older person and a caregiver limited per household were interviewed. For elder abuse
33
34 238 screening questions, participants were interviewed in private without the presence of any family
35
36 239 members, while their caregivers were interviewed separately. All interviewers underwent a short
37
38 240 training course prior to conducting the survey.
39
40
41
42

43 241
44
45
46 242 Table 1 presents the eligibility criteria for subject selection in this study. Information gathered
47
48 243 from respondents and caregivers included socio-demographic, physical health, medical history,
49
50 244 nutrition, psychological status, daily activities, health utilization, and social support and network.
51
52
53

54 245
55
56
57 246 Table 1 Eligibility criteria for the MAESTRO cohort study
58
59
60

Inclusion criteria	Exclusion criteria
<ul style="list-style-type: none"> • Older persons aged 60 years or more • Community dwelling elders living at home alone or with family or relatives in the past 12 months • Malaysian nationals • Elders who can communicate with the interviewers 	<ul style="list-style-type: none"> • Elderly residing in long term care institutions • Elders who are unable to communicate with the interviewers, eg. post-stroke, mentally disabled, severe cognitive impairment. • non-resident in the area in the previous 12 months or foreign nationals

247 **Recruitment and follow-up interviews**

248 Follow-up interviews will be performed on the 3rd and 5th year. Participants will be tracked for
 249 at least 5 years, or until death. To reduce losses to follow-up, a brief telephone interview will be
 250 conducted a year after the follow-up interview to detect any change of residence and health
 251 status in the past year. To gain rapport and ensure high response rate from selected subjects, the
 252 research team engaged actively with the local community via the Village Safety and
 253 Development Committee (VSDC). The VSDC acted as a mediator, assisting researchers in
 254 identifying selected house addresses and informing local residents about the possible visit by the
 255 research team.

256
 257 Prior to the commencement of the actual study, a pilot study was conducted to evaluate the
 258 feasibility of each instrument on a sample of older adults with a similar age range and geographic
 259 area. This exercise contributed to the training of interviewers and development of skills to
 260 administer the questionnaire, in order to achieve homogeneity in data collection.

261

262 **Sample size calculation**

263 We used the minimum detectable risk ratio required between an outcome and exposure to
264 estimate the sample size. The minimum detectable risk ratio was estimated to be around 2.0 for
265 an outcome (i.e. elder mistreatment) of 10% based on a previous pilot study conducted. Power
266 and a 2-sided alpha were set a priori at 80% and 0.05. Design effect due to complex sampling
267 was estimated to be 2.0. To account for loss to follow-up and mortality in 5 years, the sample
268 size was inflated by 30%. The calculated sample size required was 2470.

269 **Assessment and operational definitions**

270 *Elder mistreatment*

271 The primary outcome of interest is elder mistreatment, or elder abuse and neglect (EAN). Older
272 persons refer to those aged 60 and more, in line with the definition established by the United
273 Nations World Assembly on Ageing, Vienna, 1982 and adopted by Malaysia. The definition of
274 elder mistreatment was based on the WHO framework on violence: any abuse and neglect of
275 persons age 60 and older by a caregiver or another person in a relationship involving an
276 expectation of trust. Five types of abuse were measured including physical, sexual, financial,
277 psychological, and neglect. In this study, we identified perpetrators as caregivers or person(s)
278 whom the older adults know, or with whom they have a relationship.

279
280 An extensive review of literature was conducted, and we adapted and revised a comprehensive
281 questionnaire developed by Naughton and colleagues (2012) (21). Permission was sought from
282 the national Irish prevalence study research team to use the instrument. In our study however,
283 some items in the questionnaire were modified in order to contextualize EAN within our cultural

1
2
3 284 setting. These items were behavior-specific, referring to the types of incidents that respondents
4
5
6 285 may perceive as abusive. Behaviour-specific questions help cue respondents to think of relevant
7
8 286 incidents and respond accordingly, thereby increasing the reliability and consistency of the
9
10
11 287 reported incidents. The elderly were asked if they have ever experienced at least one incident of
12
13 288 mistreatment, i) since turning 60 years old; or ii) in the past 12 months, by a caregiver or
14
15 289 somebody with whom they have a relationship of trust.
16
17
18 290
19
20

21 291 The list of acts is presented in Table 2. Physical, sexual and financial abuse are operationalized
22
23 292 as any episode of mistreatment reported by older individuals during the reference period and
24
25
26 293 perpetrated by a caregiver or a person in a position of trust. Subsequent questions gathered
27
28 294 additional information on the frequency of events, perpetrators' characteristics, perceived
29
30 295 seriousness, injuries sustained, respondents' disclosure (or lack of), the person to whom
31
32
33 296 disclosure was made, and ensuing action following disclosure.
34
35
36 297
37
38

39 298 Similar to Naughton and colleagues' work and supported by literature elsewhere (6),
40
41 299 psychological abuse is defined as 10 or more incidents of mistreatment. When the frequency is
42
43
44 300 less than 10 it is considered to have happened if the episode(s) is perceived by the respondent as
45
46 301 having a serious impact. There is no universal or standard definition of neglect. It varies
47
48
49 302 considerably across countries and cultures. When adopting the definition of neglect, we took into
50
51 303 consideration the Malaysian context and cultural ethos, in line with the National Policy on
52
53 304 Elderly which emphasize older adults' rights to protection, welfare and dignity. In this study,
54
55
56 305 neglect is defined as a caregiver's failure to meet the elder's basic needs such as access to
57
58
59
60

1
2
3 306 medical treatment, adequate nutritional food, clean clothing, proper shelter, and clean and safe
4
5
6 307 living conditions, or the failure of caregiver to provide assistance to the elderly for basic and
7
8 308 instrumental activities of daily living. These include feeding, walking, using the toilet, dressing
9
10
11 309 and bathing, preparing food, taking medication and so on.

12
13
14 310 Table 2: Operational definitions for elder mistreatment

Type of mistreatment	Definition
Physical	<ul style="list-style-type: none"> ▪ Slapped, pushed, grabbed, or shoved ▪ Kicked, bite or hit with a fist or object ▪ Inappropriately restrained in any way, e.g. locked in room/house, tied in a chair, tied on bed, chained elderly ▪ Fed too much medicine or drugs to control ▪ Burned or scalded ▪ Threatened or assaulted with a knife, gun or other weapon
Financial	<ul style="list-style-type: none"> ▪ Stole elderly's money, things, property or documents ▪ Purposely prevented elderly from accessing their money, possessions, property, land or important documents ▪ Manipulated or forced elderly into giving money or hand over property, land, possessions or other important documents ▪ Forced or manipulated elderly into altering their will or any other financial document ▪ Deliberately forge or signed cheques or other financial documents without elderly's permission ▪ Misused the power of attorney given by elderly or forcing or manipulating elderly into giving him/her power of attorney
Sexual	<ul style="list-style-type: none"> ▪ Sexually harassed or talked in a way that made the elderly uncomfortable ▪ Touched or tried to touch in a sexual way against the elderly's will ▪ Forced or attempted to force to have sexual intercourse against the elderly's will
Psychological	<ul style="list-style-type: none"> ▪ Cursed, shouted or insulted ▪ Humiliated, belittled or embarrassed ▪ Repeatedly ignored ▪ Threatened verbally ▪ Prohibited family members, friends or doctor/nurse from visiting or vice versa

Neglect	<ul style="list-style-type: none"> ▪ Access to medical treatment ▪ Enough nutritional food ▪ Clean clothing, ▪ Adequate shelter, clean and safe living conditions ▪ Failure to provide elderly's need for support for basic activities of daily living when required such as feeding, walking, climbing stairs, going to the toilet, dressing and bathing.
---------	---

311

312

313

314 Risk and protective determinants of elder mistreatment

315 Data will be collected from various sources including self-reports by respondents and their
 316 caregivers, and physical and clinical assessment. Table 3 shows the risk and protective
 317 determinants of elder mistreatment measured at different levels of the framework.

318 Table 3. Matrix of determinants and its measurement

DETERMINANTS	MEASUREMENT
<i>INDIVIDUAL (ELDERLY)</i>	
Age	The age will be estimated based on the date of birth as recorded in the Malaysian National Registration Identification Card (NRIC). Where necessary, verification with other documents such as driving license, pension book or other government documents are performed.
Sex	Male or female as recorded in the NRIC.
Ethnicity	Ethnic status will be collected as recorded in the NRIC, mainly classified as Bumiputra Malay, Bumiputra non-Malay, Chinese, Indian or others.
Marital status	Based on current marital status as reported by the elderly, which will be categorized into married, single, divorced or widowed

Living arrangement	Living arrangement to be classified as own home, or others which includes children's home or relatives' home or other persons
Education	Elderly's level of formal schooling; categorized as none, primary, secondary or higher
Income	Elderly financial status will be measured by asking the amount of funding received every month in Ringgit Malaysia (RM). Various sources of support are recorded either current monthly income if working, monthly pension if pensionable, financial aid received through government, NGOs or official sources or estimated amount received from family members if any.
Current employment status	Elderly will be asked if they are currently employed in any capacity.
Co-morbidities (chronic diseases)	Elderly will be asked if they had being diagnosed by physician for any chronic illness, which include high blood pressure, heart problems or blood circulation problems, stroke, joint pains or arthritis, Parkinson's disease, diabetes, breathing problems (asthma, lung infections) and cancer.
Physical disability	The Katz Index of Independence in Activities of Daily Living (Katz ADL), and Lawton Instrumental Activities of Daily Living Scale (Lawton IADL), are used to assess an older adult's ability to independently perform self-care and maintenance. Katz activity of daily living has 6 items scored on a 3-point response scale (independent, some assistance, or dependent). Higher score indicates elderly's independence (22). Lawton IADL has 8 items that assess independent living skills that are considered more complex than basic ADL A summary score ranges from 0 (dependent) to 8 (independent) (23).
Physical function	Two aspects of physical function of the elderly will be measured. <ul style="list-style-type: none"> i. Walking speed– average of two readings for 2.4m walking test in seconds ii. Muscle strength – average of two readings per hand for grip strength measured by dynamometer in kPa.
Cognitive impairment	The Elderly Cognitive Assessment Questionnaire (ECAQ) is a quantitative assessment of cognitive impairment among elderly people. A score lower than 6 are categorized as being cognitively impaired (24).

<i>INDIVIDUAL (CAREGIVER)</i>	
Caregiver demographic	Caregiver's age, sex, education, employment and household income level will be collected. Education, employment and income will be used as indicators to determine the socio-economic status of the caregiver.
Caregiver's substance abuse	Two items to measure caregivers' substance use including alcohol and drug problem.
Caregiver's mental illness or aggressive behavior	Elderly will be asked if their caregiver has any form of mental illness or aggressive behavior.
Caregiver caregiving and coping skills	Caregiver reactive assessment (CRA) with 24 items designed to assess specific aspects of the caregiving situation, including both negative and positive dimensions of caregiving reactions (25)
Caregiver's prior history of abuse	Caregiver will be asked if they have experience any form of child abuse or domestic violence in the past.
<i>RELATIONSHIP</i>	
Caregiver-elderly relationship	Quality of the caregiver-care recipient relationship measures the quality of the current relationship in relation to general closeness, communication, similarity of views about life, and degree of getting along. It has four items on a 4-point Likert scale response (26).
Living arrangement	Current living arrangement will be categorized as own home, or others which includes children's home, relative's home or other persons
Caregiver depression	Depression Anxiety Stress scale (DASS) is 21 items self-report scale designed to measure the negative emotional states of depression, anxiety and stress experienced by the caregiver (27)
Caregiver burden	Brief COPE is a brief measure with 28 items assessing caregiver's burden and coping mechanism. Higher scores indicate ineffective coping mechanism (28).
Dependency of elderly or caregiver	Two items that measure elderly's fear of abandonment, loneliness and tolerant towards aggressive behavior.
Religious	Salience in religious commitment scale is used to measure the extent

commitment	to which elderly and their caregiver consider their religious beliefs to be important both in general and decision making. The scale has only three items on a 4-point Likert-type scale. Total scores range from 3 to 11 (29).
COMMUNITY AND SOCIETAL	
Social support	The Duke Social Support Index (DSSI) has 11 item that measure social support received by the elderly. The higher the score, the greater support perceived by elderly (30)
Social isolation	The Lubben Social Network Scale (LSNS-6) is used to screen for social isolation among community-dwelling older. A score of 11 or less on the LSNS-6 indicate social isolation (31).
Social cohesion	The social cohesion and trust domain from the Collective Efficacy Scale (CES) is utilized. It was a 5-item Likert-type scale asking how strongly they agreed to the statements regarding people around their neighbourhood (32).

319

320 **Health consequences of elder mistreatment**

321 As delineated by our conceptual framework, consequences of EAN are categorized into quality
 322 of life, mental health, physical health/ function and mortality. This study will therefore explore
 323 four scopes of outcomes: quality of life (QoL), mortality, morbidity and health utilization. For
 324 morbidity, physical function (gait speed) and mental health (depression and sleep disturbance)
 325 will be measured, whereas health utilization is represented by hospitalization rate and frequency
 326 of health visits.

327

328 *Quality of Life*

329 The Short Form Health Survey SF-12 is utilized to measure health-related quality of life in this
 330 study. The SF-12 has both physical (PCS) and mental component (MCS) summary scales which

1
2
3 331 comprise eight concepts: physical functioning, role limitations due to physical health problems,
4
5 332 bodily pain, general health, vitality (energy/fatigue), social functioning, role limitations due to
6
7
8 333 emotional problems and mental health. Each item has a rating scale of 0 to 4. The Malay version
9
10 334 of Short Form Health Survey (SF-12) has been validated (33) and will be used in this study.
11
12

13 335

16 336 *Mental Health*

17
18
19 337 Two variables will be measured in this sphere: depression and sleep disturbance. Depression will
20
21
22 338 be assessed using the fifteen-item Geriatric Depression Scale (GDS-15). Respondents will be
23
24 339 asked whether they have experienced the symptoms described during the past week using the
25
26
27 340 yes/no format. A score of greater than 6 suggests symptoms of depression. The GDS-15 has been
28
29 341 validated among the Malay elderly population and found to be reliable, with Cronbach's alpha =
30
31 342 0.84, test-retest reliability= 0.84 and concurrent validity with the Montgomery–Asberg
32
33 343 Depression Rating Scale (Spearman's rho 0.68) (34).

34
35
36 344 Sleep disturbance is measured by the Pittsburgh Sleep Quality Index (PSQI), a validated
37
38
39 345 nineteen-item questionnaire which is used to study the quality and pattern of sleep among older
40
41 346 adults. Seven domains of sleep are captured by this instrument: subjective sleep quality, sleep
42
43
44 347 latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medications,
45
46 348 and daytime dysfunction over the last month. Respondents are asked to rate each of these seven
47
48
49 349 component on a scale of 0 to 3, with 3 reflecting the negative extreme on the Likert Scale. A
50
51 350 score of 5 or more indicates 'poor sleep' or sleep disturbance. The PSQI has a Cronbach's alpha
52
53 351 of 0.83 for all its seven components, and has been said to show high validity and reliability when
54
55
56 352 used among older adult populations across countries (35).
57
58
59
60

1
2
3 353
4
5
6 354*Mortality*

7
8
9 355 Data on mortality is obtained by regular contact with respondents' family members and
10
11 356 caregivers. Reported deaths will be crosschecked with the National Registration Department
12
13
14 357 database, which provides additional information such as the date and cause of death.
15
16
17 358

Physical health/function

18
19
20 359
21
22
23 360 Gait speed will be quantified as an indicator of physical function. In gait speed assessment,
24
25 361 respondents are asked to walk for 4 meters with or without walking aids, and the time taken is
26
27
28 362 recorded. Each participant undergoes the walking test two times, and the best score (time) is
29
30 363 taken. Walking speed has been reported to be a good predictor of adverse outcomes in
31
32
33 364 community-dwelling older people (36) and was associated with survival of older individuals
34
35 365 (37).
36
37

Hospitalization and health visit

38 366
39
40
41 367 Hospitalization is defined as being admitted at any hospital (public or private) for at least 24
42
43 368 hours in the last 12 months.
44
45

46 369 Hospitalization and frequency of health visits are determined by two questions:
47
48

49 370 1) 'In the last 12 months, did you ever visit any of the following health facilities?'

50
51
52
53 371 2) 'How many times did you visit?'

1
2
3 372 The answer options include 'private clinic,' 'government clinic,' 'social service officer',
4
5 373 'outpatient department at a hospital,' 'emergency department,' and 'admitted for at least 24
6
7
8 374 hours.' Frequency options are given as 'never', 'once', '2-3 times', '4 times or more', '1-2
9
10 375 times/week' and 'everyday'.
11
12
13
14 376

16 17 377 **Statistical analysis**

18
19 378 Data entry and management will be conducted using the SPSS Version 21.0 software program.
20
21 379 Double entry method will be performed using standardized coding and labeling approach. All
22
23 380 questionnaires will be checked after the fieldwork by a second person to minimize missing data.
24
25 381 Any missing data will be investigated and where possible, the respondent will be contacted via
26
27 382 telephone. Information collected will be kept in a locked space to which only designated
28
29 383 personnel have access. Secondary data (mortality) will be collected from the national registry.
30
31
32 384
33
34
35
36
37 385 Data will be presented as mean \pm standard deviations, percentages, odds ratios (for cross-
38
39 386 sectional analysis) or relative risks (for longitudinal analysis). The prevalence (or incidence) of
40
41 387 elder abuse, its subtypes and related factors will be estimated according to age and gender.
42
43 388 Outcomes will include quality of life, mortality, physical function (walking speed), mental health
44
45 389 (depression and sleep disturbance), and health utilization (hospitalization rate and frequency of
46
47 390 health visit). Normality of the data sets will be tested for parametric tests. Student t-test or
48
49 391 analysis of variance will be used to compare variables among the different groups for continuous
50
51 392 data. For comparison of proportions, chi-square analysis will be performed. To investigate the
52
53 393 associations between outcomes and studied parameters, multivariate analysis will be employed.
54
55
56
57
58
59
60

394 Possible confounding factors found in univariate analysis will be adjusted in multivariate
395 analysis.

396
397 Complex sampling regression analysis will be performed, taking the sample design into account.
398 This procedure will estimate variances by taking into account the design used to select the
399 sample, which is probability disproportional sample without replacement in this case. P value of
400 less than 0.05 will be considered statistically significant and 95% confidence interval will be
401 reported where appropriate.

402
403 At subsequent follow-ups, respondents will be compared to non-respondents with respect to
404 characteristics such as sex, age, educational level and health status to detect any systematic
405 differences between these two groups.

406

407 **ETHICAL ASPECTS**

408 The study protocol was submitted to and approved by the Medical Ethics Committee of the
409 University of Malaya Medical Center (MEC Ref 902.2) and Malaysian National Medical
410 Research Register (NMRR-12-1444-11726). Written permission from the relevant authorities at
411 the community level was also obtained. Respondents' written, informed consent was
412 undertaken prior to the baseline interview.

413

414 All respondents were provided with various hotline numbers to report abuse including hotlines
415 dedicated for domestic violence and child abuse such as Talian Nur 15999, Teledera toll-free

1
2
3 416 hotline 1-800-88-3040, and the contact numbers of social workers and counselors available in the
4
5
6 417 district. In the event of disclosure of abuse during the interview, respondents would be advised to
7
8 418 discuss strategies to deal with this problem with family members or a trusted person. They would
9
10
11 419 also be referred to the social worker or health officer of the district if circumstances were judged
12
13 420 to be life-threatening, or if direct requests were made. Respondents' rights and autonomy were
14
15 421 observed during the entire research process.
16
17
18 422
19
20

21 423 **DISCUSSION**

22
23
24 424 The MAESTRO cohort study aims at estimating the prevalence and incidence of elder abuse,
25
26 425 identifying its risk factors and characteristics of perpetrators, and assessing its health
27
28
29 426 consequences among community-dwelling older Malaysians. This study is one of the pioneering
30
31 427 prospective cohort studies that explore the issue of elder abuse and neglect in this region,
32
33
34 428 particularly among South East Asian countries.
35
36
37 429

38
39
40 430 There are several strengths of this study. First, the prospective study design with a long follow-
41
42 431 up period is appropriate to determine causality between predicted outcomes and exposure (abuse
43
44 432 and neglect). We focus not only on epidemiological characteristics of elder abuse, but also the
45
46
47 433 relationship between determinants at different levels and elder abuse. This study thus is able to
48
49 434 evaluate the impact of social environment and elucidate other risk factors of abuse. Second, we
50
51 435 are able to follow-up a group of respondents who report having experienced abuse, and assess a
52
53
54 436 range of outcomes including mortality, morbidity and health utilization. Active recruitment and
55
56 437 face-to-face interview ensured a highly personalized contact with respondents to increase the
57
58
59
60

1
2
3 438 response rate and retain participants. Face-to face interview is useful to obtain more accurate
4
5
6 439 information as older respondents who have difficulty understanding can directly ask the
7
8 440 interviewers for explanation. Using the census provided by the national Department of Statistics
9
10 441 as our sampling frame, the MAESTRO study subjects can be considered representative of the
11
12 442 Malaysian rural older population.
13
14
15
16 443
17
18

19 444 One major limitation of this study is the locality in which data was collected. As the focus in on
20
21 445 rural community dwelling older adults in the district of Kuala Pilah, generalizability of our study
22
23 446 findings to the urban elderly populace could be an issue. Results from this study however will
24
25
26 447 provide robust evidence and re-inforce the need for programmes to raise awareness, and
27
28 448 interventions at the appropriate level to address elder abuse and neglect in Malaysia.
29
30
31 449

32
33
34 450 Upon completing the baseline assessment, we gathered a number of lessons which would be
35
36 451 useful for other researchers when conducting a similar study. Active engagement of the local
37
38 452 community is extremely important. In rural areas where the social fabric is largely intact and
39
40 453 dynamics of social structure is different from that of the urban community, getting the local
41
42 454 leaders or influential figures of the locality into the picture will facilitate rapport building with
43
44 455 residents and smoother data collection. It is crucial that the research team listens to the local
45
46
47 456 people's needs and suggestions, understands their cultural norms and expectations, and always
48
49 457 attempts to create a win-win situation throughout the research processes. Employing local people
50
51 458 as part of the research team can be an effective strategy to win the trust of the local community,
52
53 459 as the presence of familiar faces will make the elderly feel 'at home' rather than viewing the
54
55 460 researchers as outsiders who should be treated with suspicion. In our case, we got several
56
57
58
59
60

1
2
3 461 authoritative bodies involved; the local leaders, local police force, local health workers, district
4
5 462 office, Ministry of Health, and Ministry of Rural and Regional Development. Engagement of
6
7
8 463 multiple and cross-sectoral partners not only ensures researchers' safety but increases
9
10 464 accountability and transparency of the research process.
11
12
13 465

14
15 466 With regards to a sensitive subject like abuse and neglect, an ethical dilemma might arise as to
16
17 467 what is the subsequent action by the interviewer upon identifying abuse victims. Indifference or
18
19
20 468 lack of response by the researcher may create misunderstanding among the local elderly, apart
21
22 469 from going against the principles of ethics in research. This points to the need for thorough
23
24 470 planning before going onto the ground. Adequate information on the local resources, healthcare
25
26
27 471 and social support system is crucial to identify the channels through which abuse victims can
28
29 472 receive help. We collaborated with the local health district office and engaged local health
30
31 473 personnel and social workers, in order to facilitate referral of abuse victims for further
32
33
34 474 assessment and assistance. However, being a relatively new issue in the healthcare system,
35
36 475 limitations were inevitable: we were uncertain of how fast the referral process worked, and
37
38 476 whether follow-up was done accordingly. Lack of expertise was another overwhelming issue.
39
40
41 477 Health workers comprised mainly medical officers with no official training in geriatrics or
42
43 478 gerontology. Consequently, the research team in collaboration with the Health State Department
44
45
46 479 provided a series of training on detection and management of EAN for all the district medical
47
48 480 officers and nurses working in public health facilities.
49

50
51 481
52
53 482 Incentives are without doubt an effective retention strategy in a cohort study. We provided both
54
55 483 pecuniary and non-pecuniary inducements at different phases of baseline assessment. Our
56
57
58
59
60

1
2
3 484 observation was that, despite pecuniary incentive being more attractive, it has a number of
4
5
6 485 drawbacks. Collecting data in a rural setting forced our team members to carry huge amount of
7
8 486 cash from one place to another, which was highly risky and unfeasible. There were attempts by
9
10 487 some respondents to profit from what was offered, thereby creating ill feelings and resentment.
11
12 488 Non-monetary incentives in the form of small gifts and souvenirs were found to be more
13
14 489 reasonable and practical.
15
16
17
18 490

19
20 491 Logistics plays a huge role in determining the flow and success of research processes, mainly
21
22 492 data collection. When conducting studies in rural areas of developing countries where the local
23
24 493 topography has not been properly mapped out, researchers need to anticipate few issues: the
25
26 494 available map may be outdated so locating addresses can be a challenging task. Some areas can
27
28 495 be difficult to reach via ordinary transportation, and previous physical construction or
29
30 496 infrastructure might have undergone transformation at a speed faster than what those in charge of
31
32 497 survey and mapping are able to track. While locating the addresses of study subjects, we
33
34 498 encountered difficulties as mentioned above, despite being provided with maps of the
35
36 499 neighborhood.
37
38
39
40
41
42

43 501 In conclusion, the MAESTRO study is one of the first few cohort studies exploring the issue of
44
45 502 elder mistreatment in the South East Asian region. It will greatly contribute to a better
46
47 503 understanding of the subject of abuse and neglect among older adults in a middle income and
48
49 504 developing country. The lessons we learnt in the initial phase of the study are valuable, and will
50
51 505 act as a guide during the next phase.
52
53
54
55
56
57
58
59

507 FUNDING AND ACKNOWLEDGMENT

508 This study was peer reviewed and supported primarily by the following grants: University of
509 Malaya Research Grant (RG468-12HTM) and University of Malaya Grant Challenge on
510 Preventing Elder Abuse and Neglect Initiative (PEACE) (GC001B-14HTM). The authors would
511 like to thank the Negeri Sembilan State Department of Health, Kuala Pilah District Health Office
512 and Seremban District Health Office for administrative and logistic support. We also thank Dr.
513 Corina Naughton, University College Dublin, Ireland for permission to use the elder abuse
514 questionnaire.

515 516 517 COMPETING INTERESTS

518 No conflict of interest has been declared by the author(s).

520 AUTHORS' CONTRIBUTION

521 CWY, NNH, RS, RY, FH, NI, and SK conceived the study design. CWY, NNH, RS and RY
522 prepared and drafted the manuscript. RS, SK, NI, DP, SNA, IAR, ZMA, SO, NCW, TMP, MIA,
523 TNP, KC, PB and AB contributed to the study protocol in their areas of expertise. RS, SK, NI,
524 DP, NCW, SNA, IAR, and ZMA were involved in acquisition of data. CWY and NNH were the
525 principal investigators and led the grant application. All authors approved the final manuscript.

Abstract

Introduction: Despite being now recognized as a global health concern, there is still inadequate amount of research into elder mistreatment especially in the low and middle income region. The purpose of this paper is to report on the design and methodology of a population-based cohort study on elder mistreatment among the older Malaysian population. The study aims at gathering data and evidence to estimate the prevalence and incidence of elder mistreatment, identify its individual, familial and social determinants, and quantify its health consequences.

Methods and analysis: This is a community-based prospective cohort study using randomly selected households from the national census. A multistage sampling method were employed to obtain a total of 2496 subjects living in the rural Kuala Pilah district. The study is divided into two phases; cross-sectional study (baseline), and a longitudinal follow-up study at 3rd and 5th year. Elder mistreatment was measured using instrument derived upon previous literature and

1
2
3 modified Conflict Tactic Scales. Outcomes of elder mistreatment include mortality, physical
4 function, mental health, quality of life and health utilization. Logistic regression models are used
5
6 to examine the relationship between risk factors and abuse estimates. Cox proportional hazard
7
8 regression will be used to estimate risk of mortality associated with abuse. Association annual
9
10 rate of hospitalization and health visit frequency and reporting of abuse will be estimated using
11
12 Poisson regression.
13

20 Ethics and dissemination: The study has been approved by the Medical Ethics Committee of the
21
22 University of Malaya Medical Center (MEC Ref 902.2) and Malaysian National Medical
23
24 Research Register (NMRR-12-1444-11726). Written consent was obtained from all respondents
25
26 prior to baseline assessment and subsequent follow up. Findings will be disseminated to local
27
28 stakeholders via forums with community leaders, health and social welfare departments; and
29
30 published in appropriate scientific journals and presented at conferences.

43 **Strengths and limitations of this study**

- 44 • This study is among the first few cohort studies investigating into elder mistreatment in
45 the South East Asian region.
- 46 • It has a prospective study design with a long period of follow-up, with emphasis not only
47 on epidemiological characteristics of elder mistreatment but also on determinants at
48 different levels of framework and measuring consequences of abuse.
49

- The study subjects are representative of the rural Malaysian older population as the sampling frame is derived from the national census.
- Face-to-face interview, active engagement of local community and personalized contact to ensure high response rate.
- Given the study focuses on older adults in the rural area, therefore generalizability of findings to the urban older Malaysians can be an issue.
- Exclusion of group most at risk of elder mistreatment, in particularly older adults with dementia, severe cognitive impairment, and residing in long term care institutions may potentially underreport the abuse estimates.

INTRODUCTION

The publication of “Granny Bashing” in 1975 is generally regarded as the starting point for the systematic research into elder abuse^{1,2}. More recently, there has been an expanding movement to improve elderly’s rights and their physical and emotional well-being. The World Health Organization has recognized elder mistreatment (or known as elder abuse and neglect) as a growing challenge to the field of public health, social and criminal justice worldwide. Elder mistreatment is defined as ‘a single or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an elder person’. This includes detriment to older adults by people they know or with whom they have a relationship, such as the spouse, partner or family member, friend or neighbour, or those on whom they rely for services³. Elder mistreatment is broadly categorized into physical, psychological or emotional, financial, sexual and neglect⁴.

Research findings in economically developed regions and circumstantial evidence suggest that elder mistreatment is a much more universal phenomenon than what is generally perceived by society. Elder mistreatment prevalence estimates documented by recent studies varied from as low as 1.1% to as high as 44.6%⁵, while Cooper and colleagues in an earlier review found that older population studies generated a prevalence estimate of between 3.2-27.5%. Dependent or vulnerable older people are at higher risk of abuse with nearly a quarter of them reported psychological abuse and a fifth reported neglect⁶. Early studies of elder mistreatment derived from Western countries indicated an association between abuse and gender, socioeconomic status, and ethnicity⁷⁻⁹. For instance, older women were more likely to experience abuse but this differed according to the type of abuse⁷. Older adults with cognitive and functional impairment,

1
2
3 dementia, disabilities and other chronic health problems are particularly at risk of abuse due to
4 increased dependence on caregivers¹⁰⁻¹². Caregivers' psychiatric disorders, previous history of
5 victimization, poor social support, substance use, high levels of hostility and their dependence on
6 the victim for accommodation and finance also appear to be associated with elder mistreatment

dementia, disabilities and other chronic health problems are particularly at risk of abuse due to increased dependence on caregivers¹⁰⁻¹². Caregivers' psychiatric disorders, previous history of victimization, poor social support, substance use, high levels of hostility and their dependence on the victim for accommodation and finance also appear to be associated with elder mistreatment^{11,13-15}. Others reported shared living arrangement, social isolation, loneliness and caregiver strain as risk factors^{13,16}.

The 'mapping' of elder mistreatment occurrences and understanding of its risk factors and health consequences across cultures have been significantly limited by the narrow geographical base of current research, with most being conducted in economically developed countries. This distinct gap in the existing literature is reflected by the paucity of robust studies on elder mistreatment in low and middle-income developing nations. The 'identified' risk factors may be less pertinent or not fully applicable to the more conservative Asian cultures, considering the deeply ingrained concepts of family ties and filial piety. Wu and colleagues (2014) found that many Chinese viewed elder mistreatment as non-existent in their community owing to the traditional values and cultural norms which emphasize respect of, and provision of care for parents by adult children. On the contrary, their study findings showed that at least one-third of the interviewed older adults reported experiencing some forms of abuse, suggesting the pervasiveness and lack of awareness on elder mistreatment in the community¹⁷. One of the earliest attempt to quantify the elder mistreatment issue among the Asian older populations were conducted by Dong and colleagues who performed a cross sectional survey among Chinese older adults in a medical center in Nanjing, China. They found about 35% of elderly screened positive for elder mistreatment with neglect found to be most common form of abuse, followed by

1
2
3 financial exploitation, psychological abuse¹⁸. Epidemiological evidence on elder mistreatment in
4 this region remains apathy. Further research to determine the extent of elder mistreatment and
5 the universality of its risk factors across different populations is necessary. Empirical data is
6 essential to identify older adults at risk and facilitate the development of community-specific and
7 evidence-based preventive measures.

11
12
13
14
15
16
17
18 Malaysia is a multiethnic and multicultural country with a population estimate of 29 million in
19 2014. According to the World Bank classification, Malaysia is an upper-middle income and
20 developing economy situated in the East Asia and Pacific region¹⁹. Its population consists of
21 mainly ethnic Malays (47%), followed by Chinese (25%), Indians (7%), and indigenous tribal
22 groups (11%). Population projections predict that the number of people aged 60 years and above
23 will form nearly 11 % of the national population by 2020, and this figure will double by 2040²⁰.
24
25 This substantial increase in older populace, along with rapid urbanization and changing family
26 structures will bring about greater challenges to the provision of care for the older person. Like
27 many Asian countries, most older Malaysians rely heavily on their children for care and financial
28 support. This is especially customary among those living in rural areas where there is inadequate
29 pension and social support system and limited access to medical care, as compared to that
30 enjoyed by their more affluent urban counterparts. The rural-urban migration of youths in search
31 of better job opportunities has also greatly weakened the family's perceived obligation of caring
32 for their elder members. The lack of social safety net coupled with heavy reliance on their
33 children expose the rural older population to a greater likelihood of abuse and exploitation.

1
2
3 A number of countries have enacted statutes for reporting elder mistreatment and protection of
4 the elderly. There is no specific legislation to address elder mistreatment in Malaysia to date.
5
6
7
8 The provision of the Domestic Violence Act 1994 is relatively non-specific; it covers all family
9 members including older adults within a household^{21,22}. Official or authenticated data on elder
10 mistreatment is also unavailable to gauge the true extent of the problem. While the Malaysian
11 government has demonstrated commitment to protect the rights and welfare of the elderly
12 through a number of initiatives, there remains little information from well-designed community
13 based research into the multiple dimensions of elder mistreatment. To address this need, the
14 MALaysian Elder miSTreatment pROject (MAESTRO) study was designed to estimate the
15 prevalence and incidence of elder mistreatment, describe the characteristics of perpetrators,
16 identify individual, familial, community and social determinants of elder mistreatment and assess
17 its health consequences among a representative sample of Malaysian older adults.

35 **Objective of the study and conceptual framework**

36
37
38 The overarching aims of the study are to estimate the prevalence and incidence of elder
39 mistreatment, its subtypes and multiple types of abuse; to identify the extent to which elder
40 mistreatment is predicted by individual, familial, community and social determinants, and; to
41 determine the consequences of elder mistreatment in relation to injuries, physical health and
42 function, mental health, health utilization and mortality.

49
50
51
52
53

54 This project employed a conceptual framework adapted and modified from the World Health
55 Organization. Applying the ecological approach, the framework guided the development of the
56
57
58
59
60

1
2
3 study design and selection of the range of potential determinants and outcomes of elder
4
5 mistreatment. The central thesis of this framework is the emphasis on the interaction and
6
7 dynamics of multiple determinants at various ecological levels in which victims and perpetrators
8
9 are embedded; individual, relationship, community and sociocultural. In this study, we
10
11 examined both the risk factors for, and protective factors against elder mistreatment, along with
12
13 its outcomes. Figure 1 illustrated the conceptual framework of this study.

21
22
23

24 **METHODS AND ANALYSIS**

25 26 27 **Study design**

28
29
30 This is a 5-year prospective longitudinal cohort study among community dwelling older adults
31
32 aged 60 years and older and their caregivers, residing in the district of Kuala Pilah in the state of
33
34 Negeri Sembilan, Malaysia. It commenced in November 2013 and is currently ongoing. The
35
36 study will be executed in two phases. Phase I comprises a cross-sectional study (baseline) and
37
38 phase II is a cohort follow-up study across a 5-year period. Participants will be followed up at
39
40 3rd, and 5th year.
41
42
43
44
45
46
47

48 **Sample selection and Study participants**

49
50
51 A two-stage cluster sampling was employed to select study subjects. In the first stage, one
52
53 representative district, Kuala Pilah was randomly selected from seven districts available in the
54
55 state of Negeri Sembilan. Negeri Sembilan lies in the central of Peninsular Malaysia, about 100
56
57
58
59
60

1
2
3 kilometres away from the capital city, Kuala Lumpur. Its population stands at 1.02 million
4
5 according to the national census. Compared to other districts, Kuala Pilah has the biggest
6
7 population of older adults in the state. In the second stage, the Malaysian Department of
8
9 Statistics (DoS) provided a comprehensive sampling frame based on the most recent national
10
11 census conducted in 2010. Out of 254 enumeration blocks (EBs) within Kuala Pilah, 156 EBs
12
13 were randomly chosen. Each EB contained a minimum of 15% of older individuals. A
14
15 computer-generated list of households was then provided, from which 16-20 households were
16
17 randomly selected from every EB. Maps of the local terrain provided by the DoS were used to
18
19 locate selected households. The Malaysian Department of Statistics performs the national census
20
21 every ten years and retains the most comprehensive and up-to-date information on the population
22
23 demographics ²⁰. This method of complex sampling design ensured adequate coverage of older
24
25 adults in all parts of the district, yielding a heterogeneous representative sample from the target
26
27 population.

37

38 Respondents were interviewed at home by trained personnel, using a structured questionnaire.
39
40 An older person and a caregiver limited per household were interviewed. For elder abuse
41
42 screening questions, participants were interviewed in private without the presence of any family
43
44 members, while their caregivers were interviewed separately.
45
46
47
48
49
50

51 Table 1 presents the eligibility criteria for subject selection in this study. Information gathered
52
53 from respondents and caregivers included socio-demographic, physical health, medical history,
54
55 nutrition, psychological status, daily activities, health utilization, and social support and network.
56
57
58
59
60

Table 1 Eligibility criteria for the MAESTRO cohort study

Inclusion criteria	Exclusion criteria
<ul style="list-style-type: none"> • Older persons aged 60 years or more • Community dwelling elders living at home alone or with family or relatives in the past 12 months • Malaysian nationals • Elders who can communicate with the interviewers 	<ul style="list-style-type: none"> • Elderly residing in long term care institutions • Elders who are unable to communicate with the interviewers, eg. post-stroke, mentally disabled, severe cognitive impairment. • non-resident in the area in the previous 12 months or foreign nationals

Recruitment and follow-up interviews Follow-up interviews will be performed on the 3rd and 5th year. Participants will be tracked for at least 5 years, or until death. To reduce losses to follow-up, a brief telephone interview will be conducted a year after the follow-up interview to detect any change of residence and health status in the past year. To gain rapport and ensure high response rate from selected subjects, the research team engaged actively with the local community via the Village Safety and Development Committee (VSDC). The VSDC acted as a mediator, assisting researchers in identifying selected house addresses and informing local residents about the possible visit by the research team.

Sample size calculation

Sample size calculation was estimated using the OpenEpi programme for cohort study. The minimum detectable risk ratio for primary outcome, mortality, among those exposed to abuse and non-abused was estimated to be around 2.28²³. The proportion of abuse is estimated to be an

1
2
3 average of 15% based on a previous study and systematic review conducted ^{5,24}. Power and a 2-
4
5 sided alpha were set a priori at 80% and 0.05. Design effect due to complex sampling was
6
7
8 estimated to be 2.0. To account for loss to follow-up, the sample size was inflated by 30%. The
9
10 calculated sample size required was 2418.
11

12 13 14 15 16 17 **Assessment and operational definitions**

18 19 20 *Elder mistreatment*

21
22 The primary outcome of interest is elder mistreatment. Older persons refer to those aged 60 and
23
24 more, in line with the definition established by the United Nations World Assembly on Ageing,
25
26 Vienna, 1982 and adopted by Malaysia. The definition of elder mistreatment was based on the
27
28 WHO framework on violence: any abuse and neglect of persons age 60 and older by a caregiver
29
30 or another person in a relationship involving an expectation of trust. Five types of abuse were
31
32 measured including physical, sexual, financial, psychological, and neglect. In this study, we
33
34 identified perpetrators as caregivers or person(s) whom the older adults know, or with whom
35
36 they have a relationship.
37
38
39

40
41
42 An extensive review of literature was conducted ⁵, and we adapted and revised a comprehensive
43
44 questionnaire developed by Naughton and colleagues ²⁵. Permission was sought from the
45
46 national Irish prevalence study research team to use the instrument. This instrument was
47
48 originally adapted from the revised Conflict Tactic Scale which was widely used ⁵. In our study
49
50 however, some items in the questionnaire were modified in order to contextualize elder
51
52 mistreatment within our cultural setting. These items were behavior-specific, referring to the
53
54 types of incidents that respondents may perceive as abusive. Behaviour-specific questions help
55
56
57
58
59
60

1
2
3 cue respondents to think of relevant incidents and respond accordingly, thereby increasing the
4 reliability and consistency of the reported incidents. The elderly were asked if they have ever
5 experienced at least one incident of abuse, i) since turning 60 years old; or ii) in the past 12
6 months, by a caregiver or somebody with whom they have a relationship of trust. To further
7 ensure cultural appropriateness, applicability and usefulness of the adapted abuse measures to the
8 targeted population, the research instrument was pretested and reviewed by a panel of experts
9 and face-to-face interviews with elderly. The measures was first translated from English to
10 Malay language using the forward-backward translation technique, a standard procedure for
11 questionnaire translation²⁶. The instrument underwent a review by a group of local experts in
12 public health, social work and services, physicians and geriatricians. Feedback were also sought
13 from in-depth interviews with elderly on item content, readability, clarity, item interpretation and
14 acceptability of survey procedures. There was general consensus that the proposed abuse
15 questions measured the concepts being assessed. Additional items such as lack of access to food,
16 clean clothing, medication or treatment, and shelter which was considered basic necessity for an
17 older adult were included in the final instrument. The instrument was subsequently pretested
18 with 350 elder respondents living in government subsidised residential area. The results of the
19 reliability analysis suggest all abuse measures show fair to good internal consistency. The overall
20 Cronbach's α for financial abuse, psychological abuse, physical abuse, sexual abuse and neglect
21 were 0.728, 0.730, 0.685, 0.642 and 0.709 respectively. All abuse domains were significantly
22 correlated with coefficients reported ranging from 0.10 to 0.86.
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50

51
52
53
54 The list of acts is presented in Table 2. Physical, sexual and financial abuse are operationalized
55 as any episode of elder mistreatment reported by older individuals during the reference period
56
57
58
59
60

1
2
3 and perpetrated by a caregiver or a person in a position of trust. Subsequent questions gathered
4
5 additional information on the frequency of events, perpetrators' characteristics, perceived
6
7 seriousness, injuries sustained, respondents' disclosure (or lack of), the person to whom
8
9 disclosure was made, and ensuing action following disclosure.
10
11
12
13

14
15
16 Similar to Naughton and colleagues' work and supported by literature elsewhere ⁷, psychological
17
18 abuse is defined as 10 or more incidents of abuse. When the frequency is less than 10 it is
19
20 considered to have happened if the episode(s) is perceived by the respondent as having a serious
21
22 impact. There is no universal or standard definition of neglect. It varies considerably across
23
24 countries and cultures. When adopting the definition of neglect, we took into consideration the
25
26 Malaysian context and cultural ethos, in line with the National Policy on Elderly which
27
28 emphasize older adults' rights to protection, welfare and dignity. In this study, neglect is
29
30 defined as a caregiver's failure to meet the elder's basic needs such as access to medical
31
32 treatment, adequate nutritional food, clean clothing, proper shelter, and clean and safe living
33
34 conditions, or the failure of caregiver to provide assistance to the elderly for basic and
35
36 instrumental activities of daily living. These include feeding, walking, using the toilet, dressing
37
38 and bathing, preparing food, taking medication and so on.
39
40
41
42
43
44

45
46 Table 2: Operational definitions for elder mistreatment

Type of mistreatment	Definition
Physical	<ul style="list-style-type: none"> ▪ Slapped, pushed, grabbed, or shoved ▪ Kicked, bite or hit with a fist or object ▪ Inappropriately restrained in any way, e.g. locked in room/house, tied in a chair, tied on bed, chained elderly ▪ Fed too much medicine or drugs to control ▪ Burned or scalded

	<ul style="list-style-type: none"> ▪ Threatened or assaulted with a knife, gun or other weapon
Financial	<ul style="list-style-type: none"> ▪ Stole elderly's money, things, property or documents ▪ Purposely prevented elderly from accessing their money, possessions, property, land or important documents ▪ Manipulated or forced elderly into giving money or hand over property, land, possessions or other important documents ▪ Forced or manipulated elderly into altering their will or any other financial document ▪ Deliberately forge or signed cheques or other financial documents without elderly's permission ▪ Misused the power of attorney given by elderly or forcing or manipulating elderly into giving him/her power of attorney
Sexual	<ul style="list-style-type: none"> ▪ Sexually harassed or talked in a way that made the elderly uncomfortable ▪ Touched or tried to touch in a sexual way against the elderly's will ▪ Forced or attempted to force to have sexual intercourse against the elderly's will
Psychological	<ul style="list-style-type: none"> ▪ Cursed, shouted or insulted ▪ Humiliated, belittled or embarrassed ▪ Repeatedly ignored ▪ Threatened verbally ▪ Prohibited family members, friends or doctor/nurse from visiting or vice versa
Neglect	<ul style="list-style-type: none"> ▪ Access to medical treatment ▪ Enough nutritional food ▪ Clean clothing, ▪ Adequate shelter, clean and safe living conditions ▪ Failure to provide elderly's need for support for basic activities of daily living when required such as feeding, walking, climbing stairs, going to the toilet, dressing and bathing.

Risk and protective determinants of elder mistreatment

Data will be collected from various sources including self-reports by respondents and their caregivers, and physical and clinical assessment. Table 3 shows the risk and protective determinants of elder mistreatment measured at different levels of the framework.

Table 3. Matrix of determinants and its measurement

DETERMINANTS	MEASUREMENT
<i>INDIVIDUAL (ELDERLY)</i>	
Age	The age will be estimated based on the date of birth as recorded in the Malaysian National Registration Identification Card (NRIC). Where necessary, verification with other documents such as driving license, pension book or other government documents are performed.
Sex	Male or female as recorded in the NRIC.
Ethnicity	Ethnic status will be collected as recorded in the NRIC, mainly classified as Bumiputra Malay, Bumiputra non-Malay, Chinese, Indian or others.
Marital status	Based on current marital status as reported by the elderly, which will be categorized into married, single, divorced or widowed
Living arrangement	Living arrangement to be classified as own home, or others which includes children's home or relatives' home or other persons
Education	Elderly's level of formal schooling; categorized as none, primary, secondary or higher
Income	Elderly financial status will be measured by asking the amount of funding received every month in Ringgit Malaysia (RM). Various sources of support are recorded either current monthly income if working, monthly pension if pensionable, financial aid received through government, NGOs or official sources or estimated amount received from family members if any.
Current employment status	Elderly will be asked if they are currently employed in any capacity.
Co-morbidities (chronic diseases)	Elderly will be asked if they had being diagnosed by physician for any chronic illness, which include high blood pressure, heart problems or blood circulation problems, stroke, joint pains or arthritis, Parkinson's disease, diabetes, breathing problems (asthma, lung infections) and cancer.
Physical disability	The Katz Index of Independence in Activities of Daily Living (Katz ADL), and Lawton Instrumental Activities of Daily Living Scale (Lawton IADL), are used to assess an older adult's ability to

	independently perform self-care and maintenance. Katz activity of daily living has 6 items scored on a 3-point response scale (independent, some assistance, or dependent). Higher score indicates elderly's independence ²⁷ . Lawton IADL has 8 items that assess independent living skills that are considered more complex than basic ADL. A summary score ranges from 0 (dependent) to 8 (independent) ²⁸ .
Physical function	Two aspects of physical function of the elderly will be measured. <ul style="list-style-type: none"> i. Walking speed– average of two readings for 2.4m walking test in seconds ii. Muscle strength – average of two readings per hand for grip strength measured by dynamometer in kPa.
Cognitive impairment	The Elderly Cognitive Assessment Questionnaire (ECAQ) is a quantitative assessment of cognitive impairment among elderly people. A score lower than 6 are categorized as being cognitively impaired ²⁹ .
<i>INDIVIDUAL (CAREGIVER)</i>	
Caregiver demographic	Caregiver's age, sex, education, employment and household income level will be collected. Education, employment and income will be used as indicators to determine the socio-economic status of the caregiver.
Caregiver's substance abuse	Two items to measure caregivers' substance use including alcohol and drug problem.
Caregiver's mental illness or aggressive behavior	Elderly will be asked if their caregiver has any form of mental illness or aggressive behavior.
Caregiver caregiving and coping skills	Caregiver reactive assessment (CRA) with 24 items designed to assess specific aspects of the caregiving situation, including both negative and positive dimensions of caregiving reactions ³⁰
Caregiver's prior history of abuse	Caregiver will be asked if they have experience any form of child abuse or domestic violence in the past.
<i>RELATIONSHIP</i>	
Caregiver-elderly	Quality of the caregiver-care recipient relationship measures the

relationship	quality of the current relationship in relation to general closeness, communication, similarity of views about life, and degree of getting along. It has four items on a 4-point Likert scale response ³¹ .
Living arrangement	Current living arrangement will be categorized as own home, or others which includes children's home, relative's home or other persons
Caregiver depression	Depression Anxiety Stress scale (DASS) is 21 items self-report scale designed to measure the negative emotional states of depression, anxiety and stress experienced by the caregiver ³²
Caregiver burden	Brief COPE is a brief measure with 28 items assessing caregiver's burden and coping mechanism. Higher scores indicate ineffective coping mechanism ³³ .
Dependency of elderly or caregiver	Two items that measure elderly's fear of abandonment, loneliness and tolerant towards aggressive behavior.
Religious commitment	Salience in religious commitment scale is used to measure the extent to which elderly and their caregiver consider their religious beliefs to be important both in general and decision making. The scale has only three items on a 4-point Likert-type scale. Total scores range from 3 to 11 ³⁴ .
COMMUNITY AND SOCIETAL	
Social support	The Duke Social Support Index (DSSI) has 11 item that measure social support received by the elderly. The higher the score, the greater support perceived by elderly ³⁵
Social isolation	The Lubben Social Network Scale (LSNS-6) is used to screen for social isolation among community-dwelling older. A score of 11 or less on the LSNS-6 indicate social isolation ³⁶ .
Social cohesion	The social cohesion and trust domain from the Collective Efficacy Scale (CES) is utilized. It was a 5-item Likert-type scale asking how strongly they agreed to the statements regarding people around their neighbourhood ³⁷ .

Health consequences of elder abuse and neglect

1
2
3 As delineated by our conceptual framework, consequences of elder mistreatment are categorized
4 into quality of life, mental health, physical health/ function and mortality. This study will
5
6 therefore explore four scopes of outcomes: quality of life (QoL), mortality, morbidity and health
7
8 utilization. For morbidity, physical function (gait speed) and mental health (depression and sleep
9
10 disturbance) will be measured, whereas health utilization is represented by hospitalization rate
11
12 and frequency of health visits.
13
14
15

16 17 18 *Quality of Life* 19

20
21 The Short Form Health Survey SF-12 is utilized to measure health-related quality of life in this
22
23 study. The SF-12 has both physical (PCS) and mental component (MCS) summary scales which
24
25 comprise eight concepts: physical functioning, role limitations due to physical health problems,
26
27 bodily pain, general health, vitality (energy/fatigue), social functioning, role limitations due to
28
29 emotional problems and mental health. Each item has a rating scale of 0 to 4. The Malay version
30
31 of Short Form Health Survey (SF-12) has been validated³⁸ and will be used in this study.
32
33
34
35

36 37 38 *Mental Health* 39

40
41 Two variables will be measured in this sphere: depression and sleep disturbance. Depression will
42
43 be assessed using the fifteen-item Geriatric Depression Scale (GDS-15). Respondents will be
44
45 asked whether they have experienced the symptoms described during the past week using the
46
47 yes/no format. A score of greater than 6 suggests symptoms of depression. The GDS-15 has been
48
49 validated among the Malay elderly population and found to be reliable, with Cronbach's alpha =
50
51 0.84, test-retest reliability= 0.84 and concurrent validity with the Montgomery–Asberg
52
53 Depression Rating Scale (Spearman's rho 0.68)³⁹.
54
55
56
57
58
59
60

1
2
3 Sleep disturbance is measured by the Pittsburgh Sleep Quality Index (PSQI), a validated
4
5 nineteen-item questionnaire which is used to study the quality and pattern of sleep among older
6
7 adults. Seven domains of sleep are captured by this instrument: subjective sleep quality, sleep
8
9 latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medications,
10
11 and daytime dysfunction over the last month. Respondents are asked to rate each of these seven
12
13 component on a scale of 0 to 3, with 3 reflecting the negative extreme on the Likert Scale. A
14
15 score of 5 or more indicates 'poor sleep' or sleep disturbance. The PSQI has a Cronbach's alpha
16
17 of 0.83 for all its seven components, and has been said to show high validity and reliability when
18
19 used among older adult populations across countries⁴⁰.
20
21
22
23
24

25 *Mortality*

26
27
28 Data on mortality is obtained by regular contact with respondents' family members and
29
30 caregivers. Reported deaths will be crosschecked with the National Registration Department
31
32 database, which provides additional information such as the date and cause of death.
33
34
35

36 *Physical health/function*

37
38
39 Gait speed will be quantified as an indicator of physical function. In gait speed assessment,
40
41 respondents are asked to walk for 4 meters with or without walking aids, and the time taken is
42
43 recorded. Each participant undergoes the walking test two times, and the best score (time) is
44
45 taken. Walking speed has been reported to be a good predictor of adverse outcomes in
46
47 community-dwelling older people⁴¹ and was associated with survival of older individuals⁴².
48
49
50

51 *Hospitalization and health visit*

52
53
54 Hospitalization is defined as being admitted at any hospital (public or private) for at least 24
55
56 hours in the last 12 months.
57
58
59
60

Hospitalization and frequency of health visits are determined by two questions:

- 1) 'In the last 12 months, did you ever visit any of the following health facilities?'
- 2) 'How many times did you visit?'

The answer options include 'private clinic,' 'government clinic,' 'social service officer,' 'outpatient department at a hospital,' 'emergency department,' and 'admitted for at least 24 hours.' Frequency options are given as 'never,' 'once,' '2-3 times,' '4 times or more,' '1-2 times/week' and 'everyday'.

Statistical analysis plan

Data entry and management will be conducted using the SPSS Version 21.0 software program.

Double entry method will be performed using standardized coding and labeling approach. All questionnaires will be checked after the fieldwork by a second person to minimize missing data.

Any missing data will be investigated and where possible, the respondent will be contacted via telephone. Information collected will be kept in a locked space to which only designated personnel have access. Secondary data (mortality) will be collected from the national registry.

Data will be presented as mean \pm standard deviations, percentages, odds ratios (for cross-sectional analysis) or relative risks (for longitudinal analysis). The prevalence (or incidence) of elder abuse, its subtypes and related factors will be estimated according to age and gender.

Outcomes will include mortality, quality of life, mortality, physical function (walking speed), mental health (depression and sleep disturbance), and health utilization (hospitalization rate and frequency of health visit). Normality of the data sets will be tested for parametric tests. Student t-

1
2
3 test or analysis of variance will be used to compare variables among the different groups for
4
5 continuous data. For comparison of proportions, chi-square analysis will be performed. To
6
7 investigate the associations between outcomes and studied parameters, multivariate analysis will
8
9 be employed. Possible confounding factors found in univariate analysis will be adjusted in
10
11 multivariate analysis. The relationship between various risk factors and abuse estimates are
12
13 subjected to logistic regression models. Cox proportional hazard regression models will be
14
15 performed to predict the effect of abuse on time to each outcome, e.g. risk of mortality. A
16
17 survival curve will be constructed to enable 'time-to-event' analysis and comparison between
18
19 those abused and not abused. The relationship between elder abuse and annual rate of
20
21 hospitalization and health visit frequency will be calculated using Poisson regression models.
22
23
24
25
26
27 Complex sampling regression analysis will be performed, taking the sample design into account.
28
29 This procedure will estimate variances by taking into account the design used to select the
30
31 sample, which is probability disproportional sample without replacement in this case. P value of
32
33 less than 0.05 will be considered statistically significant and 95% confidence interval will be
34
35 reported where appropriate.
36
37

38
39 At subsequent follow-ups, respondents will be compared to non-respondents with respect to
40
41 characteristics such as sex, age, educational level and health status to detect any systematic
42
43 differences between these two groups.
44
45

46 47 48 49 **ETHICAL ASPECTS**

50
51
52 The study protocol was submitted to and approved by the Medical Ethics Committee of the
53
54 University of Malaya Medical Center (MEC Ref 902.2) and Malaysian National Medical
55
56 Research Register (NMRR-12-1444-11726). Written permission from the relevant authorities at
57
58
59
60

1
2
3 the community level was also obtained. Respondents' written, informed consent was
4
5 undertaken prior to the baseline interview. The participation of both older adults and their
6
7 caregivers was voluntary. Any information provided by the respondents to the interviewers
8
9 remain confidential and anonymous. The purpose, risk and benefits, were explained making clear
10
11 to the respondents that they can opt out or withdraw at any time without affecting their rights to
12
13 access to medical care or social welfare services provided in the public facilities.
14
15

16 17 18 *Safety protocol* 19

20
21 Participating in research involving sensitive topic may have an impact on the older adults' and
22
23 the interviewers' safety and wellbeing. Disclosure of abuse or identification of abuse victims
24
25 may worsen the existing problem through either retaliation by the perpetrator or further isolation
26
27 of the victims. Other ethical dilemmas include the obligation on the researcher to take the right
28
29 action upon identifying abuse victims, and the manner in which questions on abuse are being
30
31 asked due to the sensitive nature of this subject. To minimize possible threats and risks, one older
32
33 person and one caregiver per household was interviewed and they are interviewed in separate
34
35 occasions. Interviews were held in private and without the presence of family members,
36
37 caregivers or a third person. Appointments were made with selected respondents via telephone
38
39 prior to the interviews to ensure privacy and prevent imposter interviewers from gaining access
40
41 to older person's residence. The interviewers were assigned in pairs to visit each selected
42
43 household, a strategy undertaken to ensure the safety of team members. The research team
44
45 informed the local police stations and local residential committees about the data collection. The
46
47 potential respondents were able to verify the authenticity of the survey with the police,
48
49 residential committees or health district office.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 All respondents were provided with various hotline numbers to report abuse including hotlines
4
5 dedicated for domestic violence and child abuse such as Talian Nur 15999, Teledera toll-free
6
7 hotline 1-800-88-3040, and the contact numbers of social workers and counselors available in the
8
9 district. In the event of disclosure of abuse during the interview, respondents would be advised to
10
11 discuss strategies to deal with this problem with family members or a trusted person. They would
12
13 also be referred to the social worker or health officer of the district if circumstances were judged
14
15 to be life-threatening, or if direct requests were made. Respondents' rights and autonomy were
16
17 observed during the entire research process.
18
19

20
21
22
23 Prior to the conduct of the study, a two day training session were held for all interviewers to
24
25 familiarize with the study objectives, methodology and research safety protocol. The topics
26
27 covered include general topics on elderly and aging process, types of abuse and neglect,
28
29 interviewing techniques, ethics of conducting sensitive topics, communication skills, and stress
30
31 management. The session also included role play, mock interviews, group discussions and
32
33 appropriate responses when handling difficult situations such as an elder respondent who could
34
35 be hostile, got upset or cried during the interview. A medical doctor and two counsellors who
36
37 were part of the research team provided emotional support when necessary.
38
39
40
41
42
43

44 For interviewers, it is important to be able to talk with other team members about the feeling
45
46 evoked from the interview process. The process can be emotionally demanding. At the end of
47
48 each surveyed day, regular meetings were held between the interviewers and researcher to check
49
50 for questionnaires completeness, discussed any difficulties faced during fieldwork, and identified
51
52 cases required referrals to the district health or social welfare offices. During the data collection
53
54
55
56
57
58
59
60

1
2
3 period, debriefing sessions allowing peer sharing and exchanging experiences were conducted
4
5 for the interviewers every week by two counsellors in the research team.
6
7
8
9

10 11 **DISCUSSION**

12
13
14 The MAESTRO cohort study aims at estimating the prevalence and incidence of elder
15 mistreatment, identifying its risk factors and characteristics of perpetrators, and assessing
16 mortality and its health consequences among community-dwelling older Malaysians. This study
17 is one of the pioneering prospective cohort studies that explore the issue of elder mistreatment in
18 this region, particularly among South East Asian countries.
19
20
21
22
23
24
25

26
27 There are several strengths of this study. First, the prospective study design with a long follow-
28 up period is appropriate to determine causality between predicted outcomes and exposure (abuse
29 and neglect). We focus not only on epidemiological characteristics of elder mistreatment, but
30 also the relationship between determinants at different levels and elder mistreatment. This study
31 thus is able to evaluate the impact of social environment and elucidate other risk factors of abuse.
32
33 Second, we are able to follow-up a group of respondents who report having experienced abuse,
34 and assess a range of outcomes including mortality, morbidity and health utilization. Active
35 recruitment and face-to-face interview ensured a highly personalized contact with respondents to
36 increase the response rate. Of the total 2,496 elderly respondents listed in the sampling frame
37 used for the survey, our preliminary analysis estimated 2,118 older adults participated and
38 interviewed for the baseline study, giving a high response rate of 84.9%. Approximately 378
39 older adults did not participate in the study. Reasons for non-participation were: refusal (33%),
40 living elsewhere/not at home at the time of study (31%), ineligible (11%), death (9%) and others
41
42
43
44
45
46
47
48
49
50
51
52
53

59
60

1
2
3 (16%). Face-to face interviews were useful to obtain more accurate information as older
4
5 respondents who have difficulty understanding can directly ask the interviewers for explanation.
6
7 This is a practical approach particularly in settings where a large proportion of the older
8
9 populations are still illiterate or with minimal education. Using the census provided by the
10
11 national Department of Statistics as our sampling frame, the MAESTRO study subjects can be
12
13 considered representative of the Malaysian rural older population.
14
15

16
17
18 One major limitation of this study is the locality in which data was collected. As the focus in on
19
20 rural community dwelling older adults in the district of Kuala Pilah, generalizability of our study
21
22 findings to the urban elderly populace could be an issue. Results from this study however will
23
24 provide robust evidence and re-inforce the need for programmes to raise awareness, and
25
26 interventions at the appropriate level to address elder abuse and neglect in Malaysia. Another
27
28 limitation in our study is the absence of measurement for dementia status as a risk factor or
29
30 covariate. Also, older adults living in care homes, post stroke or with severe cognitive
31
32 impairment who are most at risk of elder mistreatment were excluded in this study, likely to
33
34 underestimate the magnitude of elder mistreatment. This is a double-edged sword situation,
35
36 balancing between the need for respondents to fully understand and respond to questions
37
38 accurately, or exclusion of high risk groups that might add to underestimation of the elder
39
40 mistreatment problem. We included measures of cognitive functioning such as ECAQ to gauge
41
42 the respondents' cognitive capacity to consent to participation and ability to provide information
43
44 as accurate as possible.
45
46
47
48
49
50

51
52 Upon completing the baseline assessment, we gathered a number of lessons which would be
53
54 useful for other researchers when conducting a similar study. Active engagement of the local
55
56 community is extremely important. In rural areas where the social fabric is largely intact and
57
58
59
60

1
2
3 dynamics of social structure is different from that of the urban community, getting the local
4
5 leaders or influential figures of the locality into the picture will facilitate rapport building with
6
7 residents and smoother data collection. It is crucial that the research team listens to the local
8
9 people's needs and suggestions, understands their cultural norms and expectations, and always
10
11 attempts to create a win-win situation throughout the research processes. Employing local people
12
13 as part of the research team can be an effective strategy to win the trust of the local community,
14
15 as the presence of familiar faces will make the elderly feel 'at home' rather than viewing the
16
17 researchers as outsiders who should be treated with suspicion. In our case, we got several
18
19 authoritative bodies involved; the local leaders, local police force, local health workers, district
20
21 office, Ministry of Health, and Ministry of Rural and Regional Development. Engagement of
22
23 multiple and cross-sectoral partners not only ensures researchers' safety but increases
24
25 accountability and transparency of the research process.
26
27
28
29
30
31
32
33

34 With regards to a sensitive subject like abuse and neglect, an ethical dilemma might arise as to
35
36 what is the subsequent action by the interviewer upon identifying abuse victims. Indifference or
37
38 lack of response by the researcher may create misunderstanding among the local elderly, apart
39
40 from going against the principles of ethics in research. Researchers and interviewers involved in
41
42 the researching sensitive topics should be aware of their own behaviour and the effects of the
43
44 study on the participants. The research process itself might affect the researchers' values,
45
46 emotions and standpoints. Researchers may need support or supervision for themselves while
47
48 listening to heart wrenching experiences of older adults or dealing with sensitive issues
49
50 concerning family life. The interviewers shared their thoughts and feelings on the project, inner
51
52 personal reflections of their behaviours and attitudes and role playing various real-life scenarios
53
54
55
56
57
58
59
60

1
2
3 encountered during the fieldwork. The counsellors discussed the groups' collective experiences
4 for everyone's benefit, drawing upon constructivist debriefing methods used in counselling⁴³.
5
6

7
8 These sessions were helpful to reduce burden, stress and anxiety accumulated during the
9 interview process and also improved team dynamics and productivity in our study.
10
11

12
13 To increase respondents' privacy and protection, we asked respondents whether they were in a
14 place where they could talk alone or in private. It was important to conduct the interviews in a
15 safe and comfortable environment or when the respondents were ready to be interviewed. The
16 strategy to assign two interviewers per household was effective, with one person interviewing the
17 elder, while the other could engage with family members if present, so as to allow better privacy
18 between the interviewer and the elderly respondent. While asking questions on abuse/ neglect,
19 the respondent is interviewed alone without the presence of any family members or caregivers.
20
21

22
23 There were no adverse events or complaints reported during the conduct of the baseline
24 assessment study, hence the concern that the victims potentially at risk of subsequent abuse due
25 to their participation were minimal. Although the interviews itself might add temporary suffering
26 to the respondents while recounting their experiences, it was also an opportunity for them to deal
27 with their painful experience and facilitate the healing and recovery process.
28
29

30
31 Adequate information on the local resources, healthcare and social support system is crucial to
32 identify the channels through which abuse victims can receive help. We collaborated with the
33 local health district office and engaged local health personnel and social workers, in order to
34 facilitate referral of abuse victims for further assessment and assistance. The research team
35 referred 28 cases to the State Department of Social Welfare or Department of Health for further
36 assessment and follow-up upon interviewee's consent. However, being a relatively new issue in
37 the healthcare system, limitations were inevitable: we were uncertain of how fast the referral
38

56
57
58
59
60

1
2
3 process worked, and whether follow-up was done accordingly. Lack of expertise was another
4
5 overwhelming issue. Health workers comprised mainly medical officers with no official training
6
7 in geriatrics or gerontology. Consequently, the research team in collaboration with the Health
8
9 State Department provided a series of training on detection and management of elder
10
11 mistreatment for all the district medical officers and nurses working in public health facilities.
12
13

14
15
16 Incentives are without doubt an effective strategy to encourage participation in a cohort study.
17

18 We provided both pecuniary and non-pecuniary inducements at different phases of baseline
19
20 assessment. Our observation was that, despite pecuniary incentive being more attractive, it has a
21
22 number of drawbacks. Collecting data in a rural setting forced our team members to carry huge
23
24 amount of cash from one place to another, which was highly risky and unfeasible. There were
25
26 attempts by some respondents to profit from what was offered, thereby creating ill feelings and
27
28 resentment. Non-monetary incentives in the form of small gifts and souvenirs were found to be
29
30 more reasonable and practical.
31
32
33

34
35 Logistics plays a huge role in determining the flow and success of research processes, mainly
36
37 data collection. When conducting studies in rural areas of developing countries where the local
38
39 topography has not been properly mapped out, researchers need to anticipate few issues: the
40
41 available map may outdated as the last national census was conducted in 2010, so locating
42
43 addresses can be a challenging task. Some areas can be difficult to reach via ordinary
44
45 transportation, and previous physical construction or infrastructure might have undergone
46
47 transformation at a speed faster than what those in charge of survey and mapping are able to
48
49 track. While locating the addresses of study subjects, we encountered difficulties as mentioned
50
51 above, despite being provided with maps of the neighborhood.

1
2
3 In conclusion, the MAESTRO study is one of the first few cohort studies exploring the issue of
4 elder mistreatment in the South East Asian region. It will greatly contribute to a better
5 understanding of the subject of elder mistreatment among older adults in a middle income and

FUNDING AND ACKNOWLEDGMENT

This study was peer reviewed and supported primarily by the following grants: University of Malaya Research Grant (RG468-12HTM) and University of Malaya Grant Challenge on Preventing Elder Abuse and Neglect Initiative (PEACE) (GC001B-14HTM). The publication fee was partially sponsored by University of Malaya Population Studies Unit. The authors would like to thank the Negeri Sembilan State Department of Health, Negeri Sembilan State Department of Social Welfare, Kuala Pilah District Health Office and Seremban District Health Office for administrative and logistic support. We also thank Dr. Corina Naughton and their research team, University College Dublin, Ireland for permission to use the elder abuse questionnaire.

COMPETING INTERESTS

No conflict of interest has been declared by the author(s).

AUTHORS' CONTRIBUTION

CWY, NNH, RS, RY, FH, NI, and SK conceived the study design. CWY, NNH, RS and RY prepared and drafted the manuscript. SNA, IAR, ZMA, SO, FHM, TMP, PB and AB contributed to the study protocol in their areas of expertise. RS, SK, NI, RY, DP, SNA and IAR were involved in acquisition of data. CWY and NNH were the principal investigators and led the grant application. All authors approved the final manuscript.
