ABSTRACT

Introduction: Cancer is a growing health, social and economic problem. 1 in 3 people in the UK will develop cancer in their lifetime. With survival rates rising to over 50%, the long-term needs of cancer survivors are of growing importance. Cancer rehabilitation is tailored to address the physical or psychosocial decline in ability to engage in daily activities. Its use is supported by high-quality international, multicentre research. Incorporating strategies for self-management behaviour development into rehabilitation can prepare individuals for cancer survivorship. However, healthcare professionals will need to adjust their therapeutic interactions accordingly. Research is yet to clarify the impact of the therapeutic relationship on rehabilitation outcomes in cancer. This study aims to explore the impact of therapeutic relationships on self-management behaviours after cancer.

Methods and analysis: This qualitative study aims to understand cancer rehabilitation participants' beliefs regarding the importance of therapeutic relationships in developing self-management behaviours. A sample representative of a local cancer rehabilitation cohort will be asked to complete a semistructured interview to identify their perspectives on the importance of therapeutic relationships in cancer rehabilitation. Data obtained from the interviews will be analysed, coded and entered into a Delphi questionnaire for circulation to a local cancer rehabilitation population to determine if the views expressed by the interviewees are supported by group consensus.

Ethics and dissemination: This study was approved by Wales Research Ethics Committee 6 (15/WA/0331) in April 2016. Findings will be disseminated through the first author's doctoral thesis; peer-reviewed journals; local, national and international conference presentations; and public events involving research participants and the general public.

INTRODUCTION

The increasing incidence of cancer is a growing health, social and economic problem. Current estimates expect as many

Strengths and limitations of this study

- This study starts to explore how therapeutic relationships impact on survivorship, as perceived by cancer rehabilitation participants.
- Cancer rehabilitation participants will inform the design of future cancer services as experts in their experience.
- This foundation study will be unlikely to offer guidance on how to quantify or measure the specific impact of therapeutic relationships.

as one in three people in the UK to develop cancer in their lifetime.¹ Advancements in screening programmes and treatments have improved 5-year survival rates to over 50% for some cancers.² A joint Department of Health, Macmillan Cancer Support and NHS Improvement³ report forecasts a possible 3% annual increase in the size of this population with estimation that up to 3 million people in the UK living with a cancer diagnosis by 2030. This makes the long-term needs of cancer survivors a growing importance from a healthcare and social perspective.

Cancer rehabilitation

Cancer rehabilitation is a complex set of interventions, tailored to meet the needs of individuals who experience a decline in their physical or psychosocial ability to undertake daily activities or life roles at any point following a diagnosis.^{4 5} Cancer rehabilitation services should be multidisciplinary, focus on meeting the functional impact of cancer and cancer treatments, and aim to optimise individuals' participation in daily activities and life roles.⁶ Allied health professions (AHP), including occupational therapy (OT), physiotherapy, dietetics and speech and language therapy, play key roles in the delivery of cancer rehabilitation programmes.

The last decade has seen a rapidly expanding programme of high-quality research into cancer rehabilitation. This research portfolio has demonstrated improvements in physical and psychosocial outcomes following cancer rehabilitation.^{7–11}

Key opportunities for cancer rehabilitation to impact in improving outcomes for people with cancer include prehabilitation or preparing people for diagnostic investigations or treatment,^{12–14} supporting fluctuations in function throughout and facilitating recovery after treatment¹⁴ and supporting self-management thereby preparing individuals for cancer survivorship.¹⁵

Self-management

There is an increasing body of research guiding self-management interventions for a range of long-term health conditions including cancer.¹⁶ Much of this research is focused on the impact of patient education, skills development and self-monitoring interventions on enabling people to take control of their health.¹⁷ Using a self-management approach within a clinical context moves away from traditional rehabilitation service delivery models. Self-management expects a greater level of active participation by healthcare recipients. It also demands an adjustment to the style of therapeutic interactions by healthcare professionals.¹⁸

Therapeutic relationships

Using therapeutic relationships to support care delivery aimed at improving treatment outcomes is not unique in OT. There is also evidence supporting therapeutic relationships in other professions, including nursing¹⁹ and psychotherapy.²⁰

In addition to achieving goal-related physical rehabilitation outcomes,²¹ additional key benefits of adopting this approach in practice are the potential to facilitate the development of confidence and self-esteem by reducing anxiety.²²

In OT, the therapeutic relationship is considered one of the most significant dimensions of treatment interactions;²³ ideally built through a reflexive process whereby healthcare professionals consciously engage personal attributes and behaviours to develop therapeutic relationships with patients to optimise treatment outcomes.

Although research to date cannot provide clear associations between the impact of the therapeutic relationship on psychosocial outcomes in cancer,²⁴ due to complexity of these relationships, it does form a solid foundation from which to further look into how this powerful tool might better support self-management for those who are learning to live with or after cancer.

Theoretical framework

Self-determination theory (SDT) is a person-centred behaviour change model which encourages healthcare professionals to focus on supporting the development of personal autonomy for patient self-managing long-term conditions. Within this framework, the idea of

relatedness (identifiable as the therapeutic relationship) can be considered a key mechanism by which change is achieved.²⁵ Despite evidence supporting SDT as an effective model in healthcare, Ng *et al*²⁶ call for more research into the mechanisms that effect health behaviour change.

Boger *et al*²⁷ highlight therapeutic relationships with healthcare professionals, as part of a broader positive network, as a fundamental element in providing effective self-management support. This relationship can promote knowledge, skills, development of identity and independence commonly associated with optimal self-management outcomes, and can be a key feature in people feeling enabled to manage their own care.

METHODS

Objectives

The objectives of this study are to:

- ▶ Describe therapeutic relationships as experienced by people affected by cancer during rehabilitation.
- ▶ Identify participants' perspective of potential barriers and facilitators to effective therapeutic relationships during cancer rehabilitation.
- ▶ Understand the importance of the therapeutic relationship during cancer rehabilitation in relation to achieving participant-driven outcomes.

Setting

This qualitative study aims to explore the experiences and perceptions of participants connected with a cancer rehabilitation service located in South West Wales, UK. This service is provided by specialist oncology occupational therapists and physiotherapists based in secondary care, who work closely with specialist oncology medical, nursing, dietetics and speech and language therapy teams. The cancer rehabilitation service links with community, leisure and voluntary sector organisations across South West Wales to ensure participants have access to a holistic programme of physical, emotional and social support. The Health Board, within which this team sits, hosts the South West Wales Cancer Centre, which is responsible for providing specialist cancer services for residents of the local Health Board and one adjacent Health Board. The cancer rehabilitation service provides inpatient rehabilitation to the local oncology/haematology ward, and outpatient rehabilitation for this population.

This study focuses on the outpatient programme, which is free of charge to participants and offers a holistic needs assessment on first contact and at 12 weeks following individual and/or group rehabilitation. This service is available to individuals with all tumour sites, including blood cancers; and can be accessed by self or professional referral before, during and after surgical or oncological treatment. This includes availability for people presenting with long term or late-onset consequences of treatment. See figure 1 for tumour site

Figure 1 Relative tumour site profile of cancer rehabilitation population (2011–2015).

profile of cancer rehabilitation population from 2011 to 2015.

Participant recruitment

All people referred to and recorded on the cancer rehabilitation service database from 2011 to 2015 will be eligible to take part in this research. The cancer rehabilitation service does not provide treatment for children. Therefore, eligible research participants would include persons aged 18 years or older, having been affected by cancer of any type, at any disease stage and having completed or be in the process of participating in the local cancer rehabilitation programme (see figure 2 for details).

Recruitment to the semistructured interviews and Delphi questionnaire will follow the procedure outlined in the study overview (see figure 3). An initial list of potential research participants from the service referral database will be cross-checked against a Health Board patient information management system, to ensure that up-to-date contact details are available and ensure that undue distress is not caused by contacting the households of individuals who have not survived their cancer. Eligible participants will be posted a research invitation and preconsent form, allowing time to consider participation in the study. On return of the preconsent form using a reply paid envelope, names and contact details will be held on a password-protected database, accessed by the research team only. This will be required for the practical purposes of providing supplemental information or explanation of the study, to answer any questions, complete demographic screening questions and register participant preference for research activity, arranging of

face-to-face interviews and recording the return rate from each round of questionnaires.

A demographic data collection tool, based on the National Cancer Patient Experience Survey,²⁸ will be used to identify sample age, sex, ethnicity, highest level of education and main employment status at the time of starting rehabilitation. In addition to this, data will be collected relating to any non-cancer long-term conditions, time since first cancer treatment, whether participants have been treated for one or more cancer diagnoses and type of cancer treatment/disease responses status at the time of rehabilitation.

Following a period of 4 weeks, a second mail out will take place to participants who are yet to have responded. If no further response has been received from potential participants within the following 4 weeks, non-consent will be assumed. These individuals will not be approached again.

Participant choice

Participant collaboration in service development has been highly valued by the local cancer rehabilitation service from its inception in 2008. In an attempt to maintain this collaborative philosophy throughout the research, the study design will offer participants a choice whether they would like to take part in one semistructured interview and/or up to three Delphi questionnaires.

Ideally, all participants who identify a preference to participate in semistructured interviews will be accommodated. However, in the event that there are more volunteers for the semistructured interviews than are required, participants will be advised during screening

Figure 2 Sampling procedure.

that the interview cohort will be selected from volunteers to provide best fit representation of variables, including tumour site, disease stage, sex and age by the variables' percentage proportion of the total local cancer rehabilitation population. Those participants who indicate a preference for interview, but are not selected, will be asked to consider taking part in the Delphi Technique in order to continue their involvement in the study.

Data collection

Data collection for this study will take place in two stages. The first stage will include semistructured interviews. The second stage will use a Delphi Technique.

Semistructured interviews

Semistructured interviews will offer local cancer rehabilitation participants the opportunity to describe their experiences of therapeutic relationships with local practitioners. These data will inform the first round of themes for the Delphi questionnaires. This is aimed to reduce the potential for value judgements to be imposed on the research by the principal investigator. It is estimated that 20 interview participants can be selected to form a representational sample of the local cancer rehabilitation population. The research team

reserves the decision to cease interviewing before this quota is reached if data saturation occurs.²⁹

A semistructured interview schedule (see table 1) will be piloted and then used to facilitate face-to-face interviews. The interviews will be conducted by the principal investigator who is a member of the specialist oncology therapy team which provides a local cancer rehabilitation programme. A participant briefing will precede each interview, during which informed consent will be confirmed for audio-recording of the interview. It is anticipated that the interviews will last no longer than 60 min, and will take place in an agreed NHS, cancer charity or other location offering a suitably quiet, comfortable and confidential environment. A debriefing opportunity will follow each interview, to ensure that the research participant is aware of the purpose of, and proposed use of the interview content; provide support and signposting to appropriate services if the participant found the interview upsetting.

The interview transcripts will be analysed by the principal investigator using the content analysis framework offered by Graneheim and Lundman.³⁰ Each interview transcript will be read, identifying meaning themes including words, phrases and sentences relating to the therapeutic relationships in cancer rehabilitation. These will then be condensed and grouped into themes. It will be these themes which are used to design the first Delphi questionnaire rather than professionals' preconceived codes.³¹

In order to cross-check data analysis to ensure data quality, consistency in approach and transparency of analytical decision-making,²⁹ 20% of the interview transcripts will be analysed by a second reviewer. A third reviewer will be used where needed to undertake a further analysis and used if thematic discrepancies occur between the first and second reviewer.

Reflexivity

Stanley and Nayar³² advise a reflexive approach to managing the relationship between the researcher and the research participants. Maintaining a research journal, which articulates the experiences of the practitioner-researcher relationship with study participants, is one method which will be used to ensure study rigour. This will explore the advantages and disadvantages of having a prior therapeutic relationship with research participants on eliciting accurate research data which is a true reflection of the participants' beliefs. This journal will also articulate the reasoning behind decision-making during data analysis.

In addition to this, the principal investigator is skilled in recognising if the research relationship runs the risk of transitioning to a therapeutic relationship as a result of rapport building. Redirecting the activity back to the research topic, or sensitively terminating the research activity and offering aftercare will ensure participant safety and research validity.²⁹ Ongoing data analysis cross-checking and monthly discussion in formal

Figure 3 Study overview.

academic supervision with research mentors will provide impartiality to the analysis and help to minimise practitioner bias.³³

Delphi technique

The Delphi technique is a multistage process seeking to understand the experiences of individuals by identifying areas of consensus and diversity of opinion on a certain topic, through the use of questionnaires. Statements in the first Delphi questionnaire will be designed based on the themes which emerge from the semistructured interviews. It will be piloted and sent to the research participants for whom a returned consent form is held. The participants will be asked to rate each statement along a five-point Likert Scale, where 0 indicates 'of no importance at all', and 4 indicates 'of absolute importance'. Participants would also be invited to rank, in order of importance, behaviours which typify the features of the therapeutic relationship which they perceive as important to them.

The data analysis following this first questionnaire will look to identify the diversity of opinion, highlight common viewpoints and remove irrelevant data. Participants will be invited to comment on the statements and suggest additional ideas which will also be summarised, analysed and used to generate new or modified statements which will populate the questionnaire for use in the second round.

The second questionnaire will reflect the participants' responses back to them, aiming to understand relationships between statements, clarify topics and start to

either build consensus or clarify the scope of diversity in opinions. In order to ensure the quality of the data analysis, consensus will be considered to have been achieved if there is a >75% agreement or disagreement for each statement on the questionnaire.³⁴

It is expected that there would be at least two rounds in this Delphi, to offer the opportunity to provide feedback to participants, but no more than three rounds. Following guidance provided by Keeney *et al*,³⁵ the investigator will determine the number of rounds from a pragmatic viewpoint considering the time available, the number of rounds required to scope opinion and participant fatigue. Heiko³⁶ argues that consensus without stability in responses between the Delphi rounds leaves the results open to misinterpretation. Consensus will be calculated for each round in order to determine the stability of the groups' responses. A third round, if undertaken, will seek to focus on agreement between participants, and stability of consensus or diversity in responses.

Expected outcomes of the study

Anecdotal evidence from conversations with cancer rehabilitation participants to date would suggest that therapeutic relationships with healthcare providers will be perceived as of a high level of importance. There are a range of other factors which may also be considered important in developing self-management outcomes. This research offers a unique opportunity for the beliefs and opinions of cancer rehabilitation participants to drive service development.

Table 1 Semistructured interview schedule**Introduction**

Interviewer and interviewee introductions (Read verbatim to interviewee) "This interview will help us to learn more about how rehabilitation works for people affected by cancer. I will ask you questions to help you describe in your own words your thoughts, feelings and beliefs about if/how cancer rehabilitation has helped you to make life changes after cancer. We know that everybody's experience of cancer is different. I want you to feel comfortable enough to say what you really think"

Self-determination theory domains

Autonomy

Interview prompts

1. Can you tell me how you first came in contact with the cancer rehabilitation service? (eg, Keyworker/doctor/nurse/self-referral)
2. Can you tell me why you came in contact with the cancer rehabilitation service? (eg, symptoms of cancer/treatment or return to life role)

Understanding and expectations of cancer rehabilitation

1. What did you expect from cancer rehabilitation before you had your first assessment? (eg, Get back to normal?/Didn't know what else to do?)
2. Did these expectations change after starting cancer rehabilitation? If so, what made you change? If not, was there a reason?

Competence

3. What was the best part about being involved in cancer rehabilitation? (If any)
4. What was the worst part about being involved in cancer rehabilitation? (If any)
1. Has taking part in cancer rehabilitation helped to make changes to your lifestyle or behaviour? (If so, what types of changes have been made? If not, was there a reason?)

Participant perspective of relatedness

2. Can you tell me how important to you it has been to make changes to your lifestyle or behaviour?
3. Can you tell me how confident you feel in maintaining any changes into the future?

Importance of relatedness

1. Can you tell me what you think the rehabilitation team does the best?
2. Can you tell me what the rehabilitation team could do better?
3. Is there anything that the rehabilitation team did or said that stands out in your memory? (eg, special/significant/specific moments that were good or bad)
1. How important has the relationship between you and the rehabilitation team been in making lifestyle or behaviour changes?
2. Many people think of rehabilitation being provided by NHS therapists. Sometimes other practitioners have an important role in your recovery from cancer. Is there anyone else who you feel you have had a significant therapeutic relationship with?
3. Can you describe what it is about this relationship that has helped you/held you back?

Ethical considerations

This study has been reviewed by the Wales Research Ethics Committee 6. Favourable ethical opinion has been given (15/WA/0331).

DISCUSSION

There is a growing body of research which has been exploring the effectiveness of cancer rehabilitation programmes. This research has compiled a robust case for the use of physical activity in supporting people to live well with the impact of cancer or cancer treatments. However, there has been little exploration into the relationship between the rehabilitation participants and the professionals delivering the rehabilitation programmes; or the rehabilitation participants' experiences of these programmes.

Strengths and limitations

Groundwater-Smith and Mockler³⁷ propose a framework for ensuring quality of practitioner research. In addition

to observing ethical processes, it incorporates demonstrating transparency in processes, being collaborative in nature, being transformative in intent and being able to justify itself to its community or practice. This research protocol has set out to achieve these quality indicators. However, there are limitations to this study which need to be considered.

There is a risk of an overly positive bias in the data, given the existing clinical relationship between participants and the principal investigator. Professional practice doctorates were designed to close the gap between clinical practice and academic knowledge generation by enabling practitioners to approach the solution of real-world problems through researching their own field of practice.³⁸ This approach recognises the need to consider practice issues within the complexities of their context, and may limit the generalisability of the findings.

Selecting an external interviewer may have reduced the bias of the pre-existing therapeutic relationship between the participants and the principal investigator.

However, the decision for the principal investigator to conduct the interviews is congruent with the principles of practitioner research and is closely scrutinised through academic supervision and reflexive journaling. The impact of this relationship will be a point of focus in the analysis and interpretation of results.

Using the Delphi technique offers the advantage of participants' contributions via adding additional ideas and comments, reinforcing the validity of the interview findings. A Delphi technique offers participants a focused structure for providing their thoughts on personal experiences, while remaining anonymous during rounds of consensus building. Being able to reconsider and revise answers in private may also emphasise the reliability of the findings by reducing the risk of group coercion.²² Considering the participants in cancer rehabilitation to be the experts in their experience as a group is not only crucial to the design of a Delphi study; it is an opportunity for cancer rehabilitation participants to voice their opinions formally. This will add a unique angle to research into cancer rehabilitation which has been largely researched from a healthcare professional perspective.¹⁰

Therapeutic relationships have historically been a challenging construct to define. Holmqvist *et al*²² used a Delphi study to define the therapeutic relationship from a professional perspective. This research aims to build on their work by exploring rehabilitation participants' perceptions of importance of therapeutic relationships, given their role as collaborators in self-management outcome development.²⁷ It is not considered likely that this work will be able to identify therapeutic relationships as being effective in isolation from other treatment modalities. Given the focus of this study is to understand the importance, and identify barriers and facilitators, of therapeutic relationships, it is unlikely that the issues of quantifying and subsequently measuring therapeutic relationships will be able to be addressed by this study.

CONCLUSIONS

The purpose of this study is to better understand how cancer rehabilitation participants perceive the importance of therapeutic relationships, in preference to relying on professional observations. This will enable a foundation for the further development of cancer rehabilitation services. This will aim to ensure future services are fit for purpose, and inform education programmes for professionals working in cancer and non-cancer-specific settings.
