BMJ Open

Systematic review of pathways for the delivery of allergy services

Lavanya Diwakar, Carole Cummins, Richard Lilford, Tracy Roberts

ABSTRACT

Objectives: The incidence and prevalence of allergies worldwide has been increasing and allergy services globally are unable to keep up with this increase in demand. This systematic review aims to understand the delivery of allergy services worldwide, challenges faced and future directions for service delivery.

Methods: A systematic scoping review of Ovid, EMBASE, HMIC, CINAHL, Cochrane, DARE, NHS EED and INAH^TA databases was carried out using predefined inclusion and exclusion criteria. Data on the geographical region, study design and treatment pathways described were collected, and the findings were narratively reported. This review followed the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines.

Results: 205 publications were screened and 27 selected for review. Only 3 were prospective studies, and none included a control group. There were no eligible publications identified from North America, Africa, Australia and most parts of Asia. Most publications relate to allergy services in the UK. In general, allergy services globally appear not to have kept pace with increasing demand. The review suggests that primary care practitioners are not being adequately trained in allergy and that there is a paucity of appropriately trained specialists, especially in paediatric allergy. There appear to be considerable barriers to service improvement, including lack of political will and reluctance to allocate funds from local budgets.

Conclusions: Demand for allergy services appears to have significantly outpaced supply. Primary and secondary care pathways in allergy seem inadequate leading to poor referral practices, delays in patient management and consequently poor outcomes. Improvement of services requires strong public and political engagement. There is a need for well-planned, prospective studies in this area and a few are currently underway. There is no evidence to suggest that any given pathway of service provision is better than another although data from a few long-term, prospective studies look very promising.

INTRODUCTION

The incidence and prevalence of allergic diseases has been steadily increasing globally. It is recognised that there has been an increase in the prevalence of allergies in children and young adults with each passing decade. Despite this increasing need, allergy services have not improved worldwide. It is now well established that developed countries bear a higher burden of allergic disease. Nevertheless, allergy services have remained woefully poor with very limited and patchy specialist service availability. This shortfall in service availability and the inherent heterogeneity of limited available services has been the focus of multiple expert body reviews in the UK, which have called for...
increased investment in allergy management and for reorganisation of allergy services.\textsuperscript{18–22}

One of the major barriers to service planning in allergy is the lack of political engagement and reluctance to allocate funds from the local budget for improving allergy services.\textsuperscript{23, 24} Allergy is not generally perceived as a serious condition with major implications for health and quality of life. There is a growing body of evidence to the contrary, however. It is now established that children with food allergies are more anxious than those with insulin-dependent diabetes and tend to have overprotective and very anxious parents.\textsuperscript{25} This is also true of adolescents with a history of anaphylaxis.\textsuperscript{26} In addition, the costs of allergies can be considerable. Allergy and related conditions are estimated to cost the UK NHS about £1 billion per year.\textsuperscript{27} Productivity losses associated with allergic rhinitis in the USA were higher than those due to stress, migraine and depression.\textsuperscript{28} Studies have shown that effective allergy services can not only improve quality of life, but can also be cost-saving.\textsuperscript{29, 30} Hence, there is an urgent need to impress on policymakers the importance and wisdom of investing in the improvement of allergy services.

There is currently no agreement on how allergy services should be structured. In the UK and Europe, Primary Care Physicians – known as GPs or General Practitioners in the UK – (PCPs) diagnose and manage the majority of individuals with allergies\textsuperscript{2} whereas in Australia and the USA, specialist services provide the bulk of allergy care.\textsuperscript{9} Allergy service delivery by non-clinician practitioners such as pharmacists and dieticians, while possible, is not optimally used.\textsuperscript{22} Various pathways have been suggested and are being tested.\textsuperscript{23, 31, 32} However, it is not yet clear whether any particular model of service delivery may be preferable to the others.

The aim of this systematic review is to assess published approaches to allergy service delivery. The objective is to identify and appraise these publications to gain an understanding of the advantages as well as challenges associated with these service pathways; and also to explore current ideas regarding the future direction for these services.

\textbf{METHODS}

The Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines were followed in conducting this systematic scoping review. The PRISMA checklist is supplied as online supplementary file S1.

\textbf{Data sources and search strategy}

A systematic search of the literature was carried out to identify articles related to allergy service pathways in humans. Search terms included allergy, eczema, care, service and pathway (see online supplementary file S2). MEDLINE, EMBASE, HMIC, CINAHL, Cochrane, DARE, NHS EED and INAHTA websites were searched for the purposes of this review. Searches included publications indexed until the 4th of October 2016. In order for the MEDLINE searches to be relevant, we stipulated that two papers selected a priori\textsuperscript{33, 35} should be identified in the search. References within the publications identified as relevant were individually examined to identify more articles of interest. Publications citing the chosen articles were also carefully examined for relevance.

\textbf{Selection of literature}

After discarding duplicates, the title and abstract of the articles were examined for relevance. Where these were not informative, the full text of the publication was reviewed. Articles were included for review if they discussed pathways for the delivery of allergy or eczema services. Publications which reported opinions, conference abstracts, case reports or case series were excluded. Non-English language articles were not included in the review. Asthma service pathways were also not considered. One of the researchers (LD) carried out the searches with help and advice from an information specialist from the University of Birmingham. LD screened all the articles as per the predetermined criteria. A total of 50% of the unscreened articles (25% each) were reviewed independently by two of the coauthors (TR and CC). Disagreements, if any, were resolved through discussion and consensus.

The PRISMA flow chart for selection of articles is shown in figure 1.

\textbf{Data extraction and analysis}

The data extraction form was piloted initially using a few publications. Appropriate modifications were made before starting the full extraction process.

The data were extracted by LD using extraction table that was previously agreed with the coauthors. Data extraction was scrutinised independently by two other authors (CC and TR).

For each publication, the author, year of publication, geographical region of interest, type of study (report, discussion, consensus, etc), study design (retrospective, cross section), treatment pathway (primary, secondary or both), principal findings and key recommendations were extracted.

Most of the articles were descriptive; hence the analysis followed a narrative synthesis. This is common in reviews of very heterogeneous studies which aim to describe and scope the area of interest.\textsuperscript{34} Since the objective of the report was to explore options for service delivery, the review was designed to be inclusive. Publications were, therefore, not excluded based on quality criteria but were described and briefly critiqued as appropriate given the nature of the studies. We aimed to map the current literature and understand the type of evidence available in this area (ie, allergy pathways).
RESULTS

The database search identified 351 articles of which 158 were duplicates. Additional 12 articles were included following reference and citation searches. After consideration of the title and abstract, a further 142 articles were excluded and a total of 63 publications were screened thoroughly for their relevance to the review. Figure 1 shows a flow diagram of the papers screened, identified, retained or excluded at each stage, and the reasons for exclusion of articles as per the PRISMA guidelines.

Twenty-seven publications were included in the final review which are summarised in table 1. Only three publications describe prospective data collection alongside service reorganisation. There were no eligible prospective, randomised controlled trials identified.

| Sinnott et al (2011)<sup>23</sup> | UK | Prospective planning and implementation of care pathways | Description of a pilot project undertaken to improve allergy services in the North of England. | ✓ | ▶ Poor training of PCPs leads to inappropriate referrals due to lack of confidence in managing allergies.  
▶ Specialist services are often deluged with patients who could have been managed in primary care.  
▶ Variable tariffs for allergy pose a disincentive for trusts to develop services.  
▶ Postcode lottery exists especially for those with severe allergies. | ▶ Linking clinicians with an interest in allergy is a good way to improve standards and increase awareness of patient pathways.  
▶ Developments should support existing service provision.  
▶ Commissioners need to be educated regarding the impact of allergies.  
▶ Good transition between adult and paediatric services needed. | £1.8 million pump priming for services from the DoH, UK.  
▶ Getting commissioners in the NHS interested in improvement of allergy services was challenging.  
▶ The project helped formation of a specialist nurse group in the region as well as a good network of clinicians interested in allergy. |
| Warner and Lloyd (2011)<sup>12</sup> | UK | Discussion/pathway development | Background for the development of paediatric allergy care pathways by the Royal College of Paediatrics and Child Health (RCPCH) | ✓ ✓ | ▶ The pathways are aimed at commissioners, health professionals, patients, parents and carers.  
▶ They aim to provide a bench-mark for service provision. | ▶ Eight pathways developed by six multidisciplinary working groups.  
▶ The authors define competencies rather than criteria for onward referral, so that guidance can be applicable even when there are regional variations in service provision. | Existing literature was systematically reviewed to identify ideal pathways for care and competencies required.  
▶ Pathways for anaphylaxis, asthma/rhinitis, drug allergy, eczema, food allergy, latex allergy, urticaria and venom allergy were proposed. |
▶ Some progress since 2007  
▶ Additional trainees in adult and paediatric allergy were appointed.  
▶ The Northwest SHA spearheaded a pilot into restructuring of allergy services.  
▶ NICE had adopted a few projects for issuance of guidelines.  
▶ Some areas of concern remained unaddressed including:  
▶ Poor coding of allergy clinical work.  
▶ Patient engagement underused | ▶ Services should join up to serve the population of a defined geographic area.  
▶ Validated Patient Reported Outcome Measures (PROMs) need to be developed to evaluate the effectiveness of services.  
▶ Quality Assurance schemes should be developed for clinical allergy services.  
▶ Protocols and guidelines should be shared freely between centres.  
▶ More allergy training should be incorporated into PCP and medical student curriculum (and all other related specialty training) | Working party for this report consisted of clinical experts and patient representatives from all over the UK.  
▶ Data from the pilot study in North West were discussed in the report.  
▶ Selected publications were reviewed (non-systematic).  
▶ Views from charities supporting patients with allergy also represented.  
▶ Concerns expressed about the lack of funding for outcome evaluation with allergy service remodelling in the North West. |

<td>Levy et al (2009)&lt;sup&gt;43&lt;/sup&gt;</td>
<td>UK</td>
<td>Prospective; no control group.</td>
<td>Evaluation of a PCP with special interest clinic in allergy.</td>
<td>✓</td>
<td>– Governance and training within existing services remains poor. – Occupational allergy provision remains poor. ▶ Serious deficiencies found in the commissioner’s knowledge of the allergy needs of the local population. ▶ PCP survey in 2009 showed that most (70%) continued to rate NHS allergy services as poor (similar to 2002 survey).</td>
<td>▶ Clinical services should establish good links with the local patient groups. ▶ There should be better allergen labelling.</td>
<td></td>
</tr>
<tr>
<td>Working group of the Scottish Medical and Scientific Advisory Committee (2009)&lt;sup&gt;22&lt;/sup&gt;</td>
<td>UK</td>
<td>Report from a publicly funded organisation.</td>
<td>To report on the diagnostic and clinical allergy services within Scotland</td>
<td>✓ ✓</td>
<td>▶ High burden of allergy in Scotland; 30% children and 25% adults are affected. ▶ The levels are rising for all conditions (except perhaps asthma) and services have only improved marginally since last report in 2000. ▶ There are insufficient numbers of medical specialists, trainees, PCPs, dieticians, nurses and pharmacists trained in allergy. ▶ Service is fragmented with no collaboration between primary, secondary and tertiary services.</td>
<td>▶ Primary care staff should have access to basic initial and ongoing training. ▶ There is a need to encourage and facilitate standardised and evidence-based practice through shared protocols and pathways. ▶ Data collection, audit and research facilities in allergy should be improved to ensure better future planning of services. ▶ Regional MCN for adult allergy and a national MCN for paediatric allergy services are needed.</td>
<td></td>

</table>
| Haahtela et al (2008) | Finland | Prospective; intervention; no control group. | Nationwide allergy programme being adopted in Finland. Proposed to run between 2008 and 2018. | ✓ ✓ | ▶ Dietetic services fragmented and patchy and are not always backed up with clinician support.  
▶ Allergy curriculum in undergraduate and postgraduate medical training needs improving. | ▶ Involvement of voluntary sector should be encouraged to publicize the deficiencies in service.  
▶ Project is currently underway. Its goals include:  
– Prevention of allergic symptoms.  
– Increase tolerance against allergens.  
– Improve allergy diagnostics.  
– Increase resources for allergy management.  
– Decrease healthcare costs due to allergies. | ▶ The project builds on the very successful Finnish asthma model.  
▶ Being followed in other countries (Norway, UK), preliminary results are expected soon. |
| House of Lords Science and Technology Committee, 6th report of session 2006/7 (2007) | UK | Report from a publicly funded organisation | To explore the impact of allergy in the UK upon patients, society and the economy as a whole. | ✓ ✓ | ▶ Allergy exerts a considerable social and economic burden upon the nation.  
▶ There is a severe shortage of allergy specialists in the UK and the services lag far behind those of many countries in Western Europe.  
▶ There are problems with data collection rendering statistics imprecise and affecting service redevelopment plans.  
▶ There has been a chronic lack of training of PCPs and medical trainees in allergy, leading to problems with diagnosis and management at the primary care level. | ▶ Improved education of medical practitioners to diagnose and treat occupational allergies needed.  
▶ Improve undergraduate and PCP allergy training.  
▶ New centres should build on existing excellence.  
▶ Some specialist services can be restricted to few centres across the country.  
▶ Educators and Commissioners should work together to develop generic quality assured clinical post graduate allergy courses.  
▶ NICE to appraise immunotherapy and cost-effectiveness. | ▶ This report was published by the allergy subcommittee UK House of Lords Science and Technology Committee 2007.  
▶ Recommendations made for non-NHS management of allergies (eg, training teachers in managing allergic emergencies, supporting children with hay fever during school examinations, helping those with occupational allergies return to work, improving allergen food labelling, etc).  
▶ Authors visited numerous national and international allergy centres of repute to compile this report. |

▶ No data on existing skills.  
▶ There are also no analyses of effects of active demand management of patient flows in allergy care.  
▶ No data on allergy needs in various regions across the country. | ▶ The royal colleges should work together to set up curricula for health professional training in allergy.  
▶ Health commissioners should work with local service providers to ensure best possible service planning for their catchment areas.  
▶ Much clearer understanding of skills and competencies of the existing workforce needed.  
▶ NICE advised to provide guidance on allergen immunotherapy. | ▶ Funding identified for an allergy centre in the North West region of England.  
▶ Most of the recommendations from the House of Lords report could not be acted upon due to insufficient and unreliable data on the existing state of allergy management, according to this report. |
| Warner et al (2006) | Worldwide | Cross-section; Questionnaire survey | To define the current state of allergy training and services in the countries represented within the WAO | ✓ | ▶ Prevalence rates for allergies in the responding countries ranged from 7.5% to 40% (mean 22%).  
▶ Number of certified allergists varied widely from 1:25 million in Indonesia to 1:16,000 in Germany.  
▶ Formal certification procedure is not available for clinicians in some of the countries surveyed. | ▶ There is a very wide gap between demand and provision of allergy services worldwide.  
▶ Training of medical students, general practitioners, generalists as well as system specialists who deal with allergy must improve to ensure better care provision. | ▶ Survey sent to all WAO national society member organisations to be completed by allergists knowledgeable about services within their own countries (61 sent, 34 responses received).  
▶ Data based on impressions of these experts in some countries rather than on published data. |

- In most countries, patients are first referred to organ-based specialists before being referred to allergists.
- More tertiary level centres needed to set the standards, advance research, support training and provide expertise to primary and secondary care.
- Patients feel let down by a poor and often inaccessible service.
- Specialist services are usually not available, resulting in very long waits to see consultants where services do exist.
- Self-care can be particularly useful in allergy and should be promoted.
- Some conflict between the main two specialties offering allergy services in the UK (ie, allergy and clinical immunology).
- Immunology centres are the only providers of tertiary allergy care for most of the UK.
- Consultant immunologists are likely to be providers of tertiary level allergy care in the medium and long term for the UK.
- Waiting times for allergy patients in these clinics were long, sometimes waiting over a year for urgent appointments.
- Very few centres benefitted from dietician support.

- No compelling evidence on need or on quality of allergy services since relevant research lacking.
- Patients feel let down by a poor and often inaccessible service.
- Specialist services are usually not available, resulting in very long waits to see consultants where services do exist.
- Self-care can be particularly useful in allergy and should be promoted.
- Some conflict between the main two specialties offering allergy services in the UK (ie, allergy and clinical immunology).
- Immunology centres are the only providers of tertiary allergy care for most of the UK.
- Consultant immunologists are likely to be providers of tertiary level allergy care in the medium and long term for the UK.
- Waiting times for allergy patients in these clinics were long, sometimes waiting over a year for urgent appointments.
- Very few centres benefitted from dietician support.

- There needs to be a collaborative effort between clinical immunologists and allergists in the UK in order to improve services.
- There needs to be a collaborative effort between clinical immunologists and allergists in the UK in order to improve services.
- Questionnaires sent via three supra-regional immunology audit groups to the various participating immunology regional centres in the country.
- 17 immunology centres serving a total population of 32 million individuals responded.

- Local commissioners need to establish levels of need for services for allergy in their health community.
- Educators and Commissioners should work together to create additional training spaces for doctors.
- Guidelines for management and care pathways should be developed by NICE.

- Data obtained by review of existing literature and also by interviewing stakeholders.
- Highlights the difficulties in developing national strategy for allergy services without baseline data on needs and costs involved.
- It is important to understand the skills and competencies that exist and those that are needed from the diverse workforce to enable future development and provision of services.

Level: 1° (primary) refers to care delivered by primary care physicians, nurses and other practitioners who are non-specialist and offer services in the home or community.  
2° (secondary) services refer to those provided in hospitals by clinicians (doctors or nurses) deemed to have specialist training and knowledge relevant to the management of the condition.
Seven of the publications discussed allergy services in other parts of the world, whereas the rest are focused specifically on services in the UK. Of the 19 UK papers, 8 are reports published by governmental organisations discussing the state of allergy services in the UK. One of these reports provides a brief overview on aspects of allergy services in other European countries (Germany and Denmark). Another summarises experiences following the establishment of a pilot allergy service in the North West of England.

Reorganisation of primary care was addressed by seven articles, secondary care services were the focus of six publications, whereas four papers discuss both levels of care. The eight government reports discuss all aspects of service delivery (table 1). Three studies discussed the use of digital technology-based interventions for allergy, one of these retrospectively evaluated such a service. Findings, statements and recommendations about allergy services pathways from the included papers are reported in table 1 and are synthesised thematically.

Primary care services
PCPs in allergy service delivery
PCPs are the first-line providers of healthcare in most countries around Europe. They are well placed to provide diagnosis and management of mild and most of the moderate allergic conditions as well as to refer individuals with complex and severe allergies to specialist services. Many publications have identified that the training offered to PCPs in allergy currently is inadequate. The current inadequacies in training and the need for more information and training for PCPs in allergy were reinforced in studies reported from Scotland, Italy and Spain.

It was argued in the two European publications that a model of care which is centred on specialists or consultants is untenable in allergy. In public-funded health systems such as the UK where PCPs assess and manage the majority of patients, the burden placed by allergy and related conditions on primary care could be significant. For example, it was estimated that allergy accounts for 8% of all general practice consultations in the UK and that up to 11% of the total drugs budget is spent on allergy-related medication (including asthma and eczema).

One particular article mentioned the lack of access to secondary services as allergy’s ‘greatest unmet need’. Referral times to specialists vary considerably across Europe from over 3 months in some tax-funded health systems to as little as 1 week when specialists can be accessed privately. Across Europe organ specialists are generally more readily accessible to PCPs than allergists. In a UK-based survey of over 480 PCPs, 81.5% of the 240 PCPs who responded felt that the NHS allergy services were poor and 80% felt that secondary care provision was inadequate. These practitioners admitted to being especially anxious about treating children with food allergies, although most felt quite confident about managing common allergic conditions such as anaphylaxis, urticaria, allergic rhinitis and drug allergy.

PCPs with an interest in allergy
Two publications specifically discussed a second tier service for allergy within primary care. Such an arrangement was also proposed by the House of Lords report. In the UK, a prospective evaluation of patients referred to a General Practitioner with Special Interest (GPwSI) in allergy revealed that the services were well received, reduced the levels of secondary care referral and had a potential for cost savings. Further, PCPs in this study referred patients more readily to the GPwSI than to secondary care. However, establishing these services would need a well-defined process of accreditation and specialist mentorship, which may be difficult to achieve in most countries given the current severe shortage in the availability of specialists across Europe.

Non-physician services in primary care
Non-physician services for allergy were specifically discussed by six publications in this review. Most of the articles discuss the underusage of these professionals in allergy and suggest that there is a scope for better training of nurses, pharmacists and dieticians in allergy. Depending on the extent of training and the competencies achieved, nurses could be involved with testing, diagnosis and management of patients with allergy.

Some authors felt that pharmacists could, if adequately trained and sufficiently supervised, provide information to patients regarding techniques for using devices such as nasal sprays, eye drops, epinephrine auto-injectors as well as inhalers for allergy and related conditions. They could help patients choose over the counter medication for allergy judiciously. They can also be trained to advice individuals on the need for consultation with their PCP, where appropriate. The House of Lords committee suggested that pharmacists should be formally trained in allergy to ensure that good quality advice on allergy medication can be provided to all patients. This committee also reported concerns from clinicians regarding availability of validated tests over the counter for allergies in some establishments. There are, however, no publications to-date formally assessing the role of pharmacists in the diagnosis and management of allergy.

Barriers to providing optimal allergy care in the primary care sector
Several authors were concerned that PCPs do not receive structured instruction in allergy during their training, and very few are familiar with guidelines for the management of allergic disease. The House of Commons health committee highlighted the lack of allergy knowledge in primary care as “...one of the
principal causes of distress to patients. Some articles have specifically highlighted the significant gaps in allergy training at the undergraduate and postgraduate levels, as well as inadequate continuing medical education programmes for PCPs in allergy. This was identified as leading to inappropriate referrals to a range of specialists, lack of engagement with secondary care services for allergy, delays in diagnosis and starting appropriate management and, sometimes, to inappropriate management. All these issues resulted in poor patient experience and also cause a significant wastage of scarce healthcare resources. A retrospective review of the patients at a secondary care allergy clinic in Sussex showed that at least 42% of patients were referred for conditions that could have easily been managed in primary care, had the PCPs been appropriately trained. An Irish study also suggested that increasing awareness of common allergic conditions among PCPs can significantly reduce referrals to specialists. This suggestion was reinforced in UK government reports and other studies.

In most countries, the lack of leadership and support offered by a stable, well-staffed specialist service was identified as one of the main barriers to improvement of primary care services.

Secondary care services
Availability of specialist services
A publication by the World Allergy Organisation (WAO) has suggested that there is a great degree of heterogeneity in access to specialist allergy services across the world. Experts point out that while there has been very little increase in availability over the last few years, the demand for specialist allergy services has been steadily increasing. For example, the number of certified allergy specialists per head of population range from 1:25 million (in Malaysia) to about 1:2 million (in the UK) and 1:16 000 (in Germany). Heterogeneity in specialist training has also been highlighted with only a few countries providing certified courses to practitioners in allergy. A worldwide study by the WAO showed that paediatric allergy services are particularly underserved and children with allergic problems are often managed by general paediatricians with or without formal allergy training. This study also found that in many countries children may be managed by specialist adult physicians without appropriate paediatric training. Specialist training pathways for allergy vary markedly worldwide. In countries such as the UK, formal certification procedures in either allergy alone or in a combination of allergy and immunology exist. Similarly, in the USA, allergists/immunologists should have passed a professional examination taken after 2 years of structured specialty training. In other countries, allergy may be included as a subspecialty in general internal medicine or paediatrics training. In Germany, for example, allergology is considered a subspecialty of dermatology. In the UK, the British Society for Allergy and Clinical Immunology (BSACI) has estimated that 90% of secondary care in the UK is provided by allergists and immunologists. A study carried out in the UK has shown that allergists, who have formal training in allergy, provide allergy care to 92 million individuals in the UK. Some authors have pointed out that immunologists are indeed the sole providers of allergy services in parts of the UK. Other specialists such as those with primary qualifications in ENT, respiratory medicine or dermatology also contribute to the delivery of allergy services in many countries including about 10% of the total secondary care for allergy in the UK. Even if this broad definition of allergy specialists were to be accepted, many experts feel that allergy services remain inadequate in most countries in the face of increasing demand for these services.

Specialist centres for allergy
Some authors propose the ‘hub and spoke’ model which involves the establishment of supraregional tertiary allergy centres (or Hubs) which can support regional secondary and primary care centres (the so-called spokes) for delivery of specialist services. A few suggested that these centres should be manned by consultant adult and paediatric allergists, nurse specialists as well as adult and paediatric dieticians while providing facilities for training at least two specialist registrars in allergy. Others felt that these should be multispecialist centres (eg, chest physician, dermatologist, ENT specialist, paediatrician in addition to an allergist or clinical immunologist) that are built on existing expertise of the local area and serve as ‘clusters of expertise’. In some countries, these centres would typically be university hospitals which would receive referrals only from specialists.

Whatever their composition, most agreed that these centres could serve to educate and support primary and secondary care physicians in the region. It was suggested that they had a potential to serve as centres of excellence for adults and children with complex and severe allergies; establish a good, working network between organ-based specialists, generalists and allergists and serve to improve the overall provision of allergy services in the region.

Some experts point out that the existing shortage of specialists in allergy would be a barrier to the development of such centres. A pilot study carried out in the North West region of England found that developing large tertiary centres would not be practical in regions with large cities in close proximity to one another. They may not be cost-effective for many regions within the UK and perhaps, Europe.

The House of Commons health committee has pointed out that there are no clear data to suggest that specialist centres improve clinical outcomes in allergy management. Indeed, even in countries like Germany with a relatively high proportion of allergy specialists per 100 000 population, the numbers of emergency admissions for allergy remain high.
East England pilot study found that the lack of confidence among general practitioners while dealing with patients with allergy led to poor referral practices. As a consequence, management of simple conditions took up a disproportionate amount of specialist time and resources while individuals with complex allergies faced long waiting lists as well as inappropriate referrals to other specialists.

**Future direction for services**

While efforts are being made to improve allergy education at the undergraduate and postgraduate levels, there has been a focus also on the improvement of training of current practitioners. The Royal College of Paediatrics and Child health has developed care pathways for children which define core competencies for all those involved in managing these conditions and are freely accessible online. These are UK based but potentially can be modified to suit other countries. Such pathways embrace the current heterogeneity in service delivery while attempting to raise standards.

The ‘Hub and spokes’ model was trialled in the UK with mixed results, which was specifically discussed in a report. The authors suggested that new services should be tagged onto existing pathways and also stated that a care model of visiting specialists in secondary centres would be more welcome in some areas than the establishment of large tertiary centres. It was also suggested that models of good care can vary from one region to another.

There have been recent publications regarding the use of digital technology in the provision of allergy services. One addresses the use of telemedicine in improving communications between primary and secondary care in order to improve adult allergy pathways within the NHS, whereas another makes a case for clinical trials using information communication and technology (ICT) in management of allergic rhinitis in Europe. A publication from Ireland reported on the use of an email communication system, which received an average of only four enquiries per month over a 12-month period. Although it was rated useful by 100% of the responding non-specialists (response rate of 35%), this communication system did not reduce referrals to the specialist allergy services.

There has been a lot of interest lately in the ‘Finnish model’ of service reorganisation. This re-structuring exercise takes inspiration from the successful interventions for asthma in Finland. While acknowledging the differences between asthma and allergy and emphasising the need to understand and improve tolerance to allergens, the architects of this model hope to use the existing asthma infrastructure to improve services for allergy sufferers. They suggest that increased initial outlay aimed at preventing allergies and changing attitudes towards health alongside improving service delivery can reduce the cost and burden of allergic disease in the future. The results of this experiment are currently awaited.

**DISCUSSION**

Principal findings of the review

This systematic review aimed to identify and discuss various pathways that are relevant to the delivery of allergy services. There were large gaps in the literature pertaining to services in countries with high rates of allergy (such as Australia, New Zealand, USA) as well as very populous regions of the world including China, India, Brazil and the whole of Africa. In addition, there was a lack of well-designed studies in this area with only three prospective studies identified. None of the studies included a control group. Two of these publications describe service reorganisation on a large scale with direct involvement of the relevant health ministries.

There is clear evidence from the literature that allergy services across the world have not kept up with rising demand. The ‘allergy epidemic’ has surprised unprepared health systems globally. There has been failure on the part of governments and fund holders to acknowledge the rapid rise in allergies. Given that there are no signs of abatement in the observed increase in allergies worldwide, it is conceivable that the demand on services is set to increase even higher over the next few years. The psychosocial impact of these conditions is often overlooked. For example, atopic individuals experience significantly worse memory and cognitive ability during allergy season. Children with eczema report higher levels of anxiety and depression. In addition, these conditions currently place an inordinate financial burden on healthcare services. Urgent and effective measures are therefore needed to cope with the problem.

About three-quarters of the eligible publications in this review (18/23) are from the UK which suggests that there has been a lot of interest here in investigating the extent of the supply gap in allergy services over the last 15 years. It is striking however, that while most of these reports describe the problems with service delivery and suggest some solutions, none seem to have addressed the problem in a structured manner. There has been no response to the UK Department of Health’s request for reliable baseline data on needs of the population; costs involved in service reorganisation; and the skills and competencies of the existing workforce in order that future services can be planned.

Primary care services are key to optimal management of allergy. Appropriate management after good history taking and specific testing can easily be achieved in primary care for a majority of patients. Referral to specialist centres can be limited to only complex patients needing multidisciplinary input or those that need desensitisation therapy. However, a UK survey has shown that PCP confidence in managing allergies in children and initiating referrals appropriately is limited. While PCPs in this particular survey felt confident about managing adults, studies have shown that most individuals referred to secondary care could have been managed effectively in primary care. This serves to highlight the inadequate training received by PCPs in allergy
at undergraduate and postgraduate levels. This leads to not only poor patient experience and outcomes but is also more expensive to the health service providers.

Owing to lack of specialists in allergy, patients are often referred to specialists who can, perhaps, only deal with individual manifestations of allergy (eg, respiratory physicians for allergic asthma; ophthalmologists for allergic eye disease). Organ-based specialists play a very important role in the management of allergic disease. Indeed, in some instances (eg, children with very severe disease), their input is essential. However, specialists in allergy can provide clinically effective and potentially cost-effective services by intervening across several of these conditions for most patients.20

Scarcity and inequity of specialist allergy services is a recurring theme in many articles worldwide. Although numerous publications have made a compelling case for more specialist centres,3 18–21 33 these have not been forthcoming. Many factors appear to contribute to this apparent inertia,21 the important ones being lack of adequate central funding to increase training numbers for specialists, lack of interest in allergy services among fund holders,23 lack of clarity regarding the role of various specialists involved.21 Another important issue is the lack of formal training programmes in allergy in many countries.3 This not only blights the care of individuals with allergy in these countries, but also prevents the specialty being taken seriously by decision makers. In the case of the UK, lack of clinical codes to measure allergy activity and disagreements between the two main specialist groups that provide allergy services (allergists and immunologists) are also important issues.48 Further, in the UK, the lack of specialist services and poor referral practices within primary care have resulted in unreliable waiting list data, which are often used as a surrogate marker for need within the NHS.44 This has proved to be a barrier for further investment in services.45

It should be noted that there are no published data that support the success of large, tertiary centres. Nevertheless, it is conceivable that centres which treat large volumes of individuals will provide better outcomes for complicated patients.50 However, the lack of confidence among general practitioners while dealing with patients with allergy leads to poor referral practices leading to long waiting lists as well as inappropriate referrals to other specialists.23

There have been many encouraging advances in allergy service reorganisation in the UK and beyond. New multicentre specialist allergy centres were created in the North West of England as per the recommendations of the House of Lords report into allergy services.18 This service development encountered many barriers including non-engagement of local commissioners, non-availability of appropriately trained staff and poor coding practices.28 Nevertheless, the project was successful in improving networking among specialists across the region, improved clinical governance including audit, better regional education programmes for clinical staff and patients in allergy.23 There was an opportunity during the course of this project to prospectively collect data on patient experiences and outcomes, which was unfortunately missed.

The heterogeneity in specialist training across Europe is also being addressed with the introduction of the European Examination in Allergology and Clinical Immunology since 2008 by the European Academy of Allergy and Clinical Immunology (EAACI). The aim of this examination is to “raise standard of allergology and clinical immunology in Europe” and to “facilitate the exchange of young people trained in Allergology and Clinical Immunology” in Europe.61

The Finnish allergy model is based on the very successful restructuring of asthma care in Finland62 and is now being adapted to the management of other chronic conditions.63 In Finland, the model has been altered to incorporate the complex and heterogeneous nature of allergy but it essentially builds on the existing infrastructure developed for the asthma programme.32 The Finnish allergy plan is an ambitious project that aims to reduce the burden of allergic disease by improving tolerance and reducing the emphasis on allergen avoidance in affected individuals. The objective is to help alleviate the psychosocial aspects of allergy while improving services provided to these persons.32 Aspects of this plan have also been adopted by Norway64 and by a health authority in North West London as well as in Sheffield.65 Preliminary results from the London project are very encouraging.31 66 67 More data are awaited to ascertain whether the project has been successful and also if this success can be emulated in other regions.

Strengths and limitations of the review
The strength of this review is that it provides a systematic and comprehensive look at the reported current provision of allergy services across the world. There are some limitations to this review, mainly due to paucity of information from most countries, including some with relatively high allergy incidence and prevalence, regarding available services. Most of the literature is UK based and hence generalisability of data to other countries, especially those without publicly funded health systems may be limited. In addition, there were very few well-planned prospective studies and no controlled studies in this area. Most of the included studies had little empirical data, and therefore a formal quality assessment of the publications was not carried out. Studies not reported in the English language were excluded.

Strengths and limitations in relation to other studies
This paper is the first to comprehensively review all the published reports and journal articles on allergy services. Our review, in concurrence with a previous UK review,45 found that prospective studies in the area were lacking and that there were no data objectively comparing different levels of service delivery (eg, primary care vs secondary care).
CONCLUSIONS

There is a consensus that allergy services across the world are inadequate to meet the rising demand. There is a high degree of heterogeneity and inequity in the availability of services across the world. Untreated or poorly treated allergic conditions can have a high psychosocial impact on individuals and can place a substantial economic burden on healthcare services. Allergy training is not adequately provided in the current undergraduate and postgraduate medical curricula, which is adversely affecting patient care at all levels, especially in primary care. Primary care services are affected by poor training of practitioners and by poor access to specialists. Specialist services are hampered by the non-availability of appropriately trained personnel and poor referral practices from primary care (where applicable) which lead to long waiting lists and poor overall patient care. There is currently no clear consensus on how services should be structured although the Finnish model of service reorganisation has shown significant promise. Political engagement and patient empowerment are important to the success of these projects.

Future research

There is a need for data on service pathways from across the world, especially from countries with a high burden of allergic disease so that the extent of the problem can be identified and lessons may be learnt from successful models. Prospective data aimed at estimating the costs and outcomes of service pathways are especially important. To ensure that a service is successfully re-organised, it is important to understand the needs of the local population, their preferences for services and to estimate costs and benefits of the possible service pathways. This literature review forms part of a wider project which aims to achieve these objectives for the population of the West Midlands region of the UK.
