ABSTRACT

Objective Polycystic ovary syndrome (PCOS) is an endocrine disorder affecting approximately one in seven women who experience androgen excess, menstrual cycle irregularities, frequent anovulation and a tendency for central obesity and insulin resistance. Chronic subclinical inflammation is now recognised as being common in the context of PCOS, which led to the postulation that PCOS may fundamentally be an inflammatory process. This study aimed to: (1) evaluate serum C reactive protein (CRP)/albumin ratio as a potential predictive biomarker for PCOS; (2) compare the relationship between CRP/albumin and PCOS to variables classically associated with the syndrome.

Design Case-control study.

Setting Adult obstetrics/gynaecology, endocrinology and outpatient clinics; university hospital in Bahrain.

Participants 200 premenopausal women with a diagnosis of PCOS, and 119 ethnically matched eumenorrhoeic premenopausal women.

Main outcome measures CRP/albumin ratio, anthropometric measures, insulin resistance, androgen excess.

Results Independent of body mass index (BMI), receiver operating characteristic curve for CRP/albumin ratio as a selective biomarker for PCOS was 0.865 (95% CI 0.824 to 0.905), which was more sensitive than CRP alone. Binary regression analysis showed that CRP/albumin ratio outperformed classical correlates, Free Androgen Index and insulin resistance, in predicting PCOS for every BMI category.

Conclusion CRP/albumin ratio, a marker for inflammation related to metabolic dysfunction, was found to have a stronger association with PCOS than either androgen excess or insulin resistance. Inflammation is known to be influenced by adiposity, but relative to controls, women with PCOS have higher levels of CRP/albumin irrespective of BMI. These findings support the view that inflammation plays a central role in the pathophysiology of PCOS.

INTRODUCTION

Polycystic ovary syndrome (PCOS) is the most common reproductive disorder, affecting 5%–15% of premenopausal women

Strengths and limitations of this study

- This analysis addressed previous limitations of studies, namely small sample sizes, heterogeneous populations and confounding factors (such as body mass index), that have attempted to show polycystic ovary syndrome (PCOS) is an inflammatory process.
- The relationship between inflammation and PCOS was assessed using C reactive protein/albumin ratio, which may be a better marker for inflammation in the context of metabolic dysfunction.
- Study used waist circumference as a substitute for visceral adiposity; gold standard is CT or MRI.

worldwide,^{1 2} and the prevalence of PCOS appears to be increasing.¹ This rise may partly be attributed to improved diagnosis as well as to an increase in environmental factors that predispose to the development of this complex metabolic condition. PCOS is characterised by androgen excess, menstrual irregularities, ovulatory disturbances and is often associated with central obesity and insulin resistance (IR).^{3–5} As such, women with PCOS are at an increased risk for a number of health issues, including infertility, cardiovascular disease (CVD) and diabetes.^{3 6 7}

Possibly related to the constellation of endocrine and metabolic dysfunction they experience, women with PCOS are also found to have greater chronic subclinical inflammation,^{8–11} which is often clinically assessed by measuring serum levels of C reactive protein (CRP). CRP is a liver-derived acute phase protein produced in response to IL-6 secreted from activated cells such as macrophages and adipocytes.^{12 13} A meta-analysis of 31 studies concluded that systemic CRP levels are 96% higher in women with PCOS compared with control women.¹⁴ Collectively, these findings have given rise to the speculation that

inflammation may play a pivotal role in the pathophysiology of PCOS.^{8–10}

Elevated serum CRP levels are linked to several health risk factors experienced by women with PCOS, particularly IR and heightened risk of type 2 diabetes.^{7 15 16} Chronic inflammation also contributes to endothelial dysfunction, exacerbating the development of atherosclerotic plaques, triggering the onset of CVD.¹⁷ As such inflammation has been associated with both CVD and coronary artery disease in women with PCOS.¹⁰

In contrast to CRP, albumin is a negative acute phase response protein produced by the liver. Serum levels of albumin are reduced in individuals experiencing chronic inflammation.¹⁸ In addition to its role as a binding molecule for sex steroids,¹⁹ albumin also provides the majority of the total antioxidant capacity of normal plasma.¹⁸ The ratio of serum CRP levels over serum albumin (CRP/albumin) was found to be strongly associated with more severe metabolic dysfunction in premenopausal women with induced alterations to their ovarian hormone status.²⁰ CRP/albumin ratio was also found to be significantly higher in premenopausal women with PCOS relative to controls, and adversely predicted their bone quality.²¹ Given the ability of CRP/albumin to simultaneously capture chronic inflammation and metabolic dysfunction in premenopausal women, we hypothesised that CRP/albumin ratio may serve as a strong predictor of PCOS in a cohort of similarly aged women. This case-control study investigated CRP/albumin ratio along with classical markers, androgen excess and IR, in their association with PCOS in 319 premenopausal Bahraini Arab women.

METHODS

Patient and public involvement

The development of the research question and the study's setting was influenced by the wish many women in Bahrain have to bear children. Infertility is a consequence of PCOS,²² and the combination of both can impact women's health-related quality of life.²³ Patients were not involved in the design of the study or the recruitment. Study participants will not be recontacted by the study investigators; however, the results of this study will be disseminated to the Bahraini community through press releases of the open access publication.

Study subjects

Women with PCOS (n=200) were recruited from adult obstetrics/gynaecology, endocrinology and outpatient clinics in Manama, Bahrain. Women without PCOS (n=119) were ethnically matched, eumenorrhoeic university employees and students, and healthy volunteers representative of the Bahraini population. The sample size was based on the ability to detect differences between cases and controls with 10% precision (two-tailed t-test with $\alpha=0.05$) and 80% power, taking into account the estimated prevalence of PCOS in Bahrain of 7.5%–8.0%

(Bahraini Ministry of Health; www.moh.gov.bh/Content/Files/Publications/statistics/HS2015) and Z-value for 95% CI. Women serving as controls were examined in the follicular phase of their menstrual cycle and had testosterone levels within range. A diagnosis of PCOS was based on the 2003 Rotterdam Criteria, which requires two of the three following criteria to be met: ultrasound evidence of polycystic ovarian morphology, anovulation and hyperandrogenism.²⁴ Exclusion criteria included hyperprolactinaemia, non-classical adrenal hyperplasia, androgen-producing tumours, 21-hydroxylase deficiency, Cushing's syndrome and active thyroid disease (overt, central and subclinical hypothyroidism and hyperthyroidism). Additional exclusion criteria included extremes of body mass index (BMI; $<18\text{ kg/m}^2$ or $>45\text{ kg/m}^2$), recent/present illness and treatment affecting carbohydrate metabolism or hormonal levels, for 3 months or longer before inclusion the study. Women using antihypertensive, oral contraceptive, anti-inflammatory and lipid-lowering drugs were also excluded. Demographic information, along with detailed personal and family history of diabetes, hypertension, infertility, hypercholesterolaemia and ischaemic heart disease were obtained from all participants. This study was conducted in accordance with the Declaration of Helsinki, second guidelines.

Biochemical analysis

Peripheral venous fasting blood samples were obtained between 7:00 and 9:00 following an overnight (>12 hours) fast during the early follicular phase of the menstrual cycle (days 2 ± 5) for control women, or women with PCOS who did not present with menstrual irregularities, or any day for women with PCOS with menstrual irregularities. Serum samples were analysed for sex hormone binding globulin (SHBG) by sandwich ELISA (R&D Systems, Minneapolis, Minnesota, USA); assay sensitivity was 0.01 nmol/mL , and interassay and intra-assay precision (CV%) were 5.3% and 4.3%, respectively. Samples were tested in duplicates for adiponectin levels (Cat. No. DRP300) by sandwich ELISA (R&D Systems); assay sensitivity was 0.891 ng/mL , and interassay and intra-assay precision (CV%) were 6.5% and 3.5%, respectively.

Serum luteinising hormone (LH), follicular-stimulating hormone (FSH), thyroid-stimulating hormone (TSH), testosterone, glucose (ADVIA Centaur, Bayer Vital, Fernwald, Germany) and insulin (IMMULITE 2000, DPC Biermann, Bad Nauheim, Germany) were measured by automated chemiluminescence immunoassays. Free testosterone (FT) and bioavailable testosterone (BT) and Free Androgen Index (FAI) were determined using FT and BT Calculator (www.issam.ch/freetesto.htm). Progesterone and oestradiol serum levels were quantitated by radioimmunoassay, with comparable CV% ($<5\%$), while dehydroepiandrosterone sulfate (DHEAS) levels were measured by solid-phase competitive immunoassay (Immulite; Siemens); interassay and intra-assay CV were 9.4% and 7.0%, respectively.

Concentrations of serum albumin were analysed by photospectrometry with albumin bromocresol purple assay on a COBAS c701 Chemistry Analyzer (Roche Diagnostics, Dubai, UAE). IR was estimated by the homeostasis model assessment (HOMA-IR), defined as fasting serum insulin (IU/mL) × fasting plasma glucose (mmol/L) / 22.5. HOMA-IR values were characterised as normal (insulin sensitive) if <2.40; borderline if between 2.40 and 3.50, and high (insulin resistant) if >3.50.

Measurement of plasma high-sensitivity CRP levels was done by latex-enhanced nephelometry on a BN II Nephelometer (Dade Behring, Milan, Italy). Samples were assayed in duplicate in each analytical run; the lower limit of detection was 0.15 mg/L, and the assay range was 0.175–11.0 mg/L (initial dilution). Serial serum dilutions were made in measuring high CRP (>30 mg/L) levels. Percentile CRP values were estimated for comparison purposes.

Statistical analysis

The core outcome set of variables included assessment of CRP/albumin as a predictor of PCOS while controlling for relevant factors, such as BMI and age, and to subsequently compare the strength of the relationship between CRP/albumin and PCOS with variables known to strongly link to the syndrome, namely androgen excess and IR. The Shapiro-Wilk test was used to evaluate the distribution of the variables, and many variables for the PCOS cohort were flagged as being non-normally distributed. However, on testing for

skewness, we found the values for asymmetry and kurtosis fell between –2 and +2 for all. Thus, we used parametric tests, as suggested,²⁵ given the sample sizes were >30. We reassessed the validity of our analysis by running the Mann-Whitney U test in addition to Student's t-test for variables we had detected as being non-normal and confirmed that the results were similar. Baseline characteristics were compared using the Mann-Whitney U test and the independent samples t-test for the continuous variables and the χ^2 test for categorical variables. Numerical variables are presented as mean ± SD. Because distribution of CRP/albumin levels was skewed to the right, correlations between CRP/albumin ratio and other continuous variables were assessed using Spearman's r . Univariate general linear models were applied to test independent associations between CRP/albumin ratio and other independent variables.

The optimal cut-off level for the CRP/albumin ratio was determined by a receiver operating characteristic (ROC) curve analysis, and the areas under the curve (AUC) were measured and compared to assess the power of a model to identify patients who experienced metabolic disturbances. Cut-off values showing the greatest accuracy were determined using a sensitivity/specificity versus criterion value plot. Quartiles (ie, 0%–25%, 26%–50%, 51%–75% and 76%–100%) of CRP and CRP/albumin ratio were calculated separately in PCOS and control groups. Because the 25% quartile of CRP value in the PCOS cohort was similar to the standard normal values of

Data are presented as means (SD).

BMI, body mass index; CRP, C reactive protein; HOMA-IR, homeostatic model assessment for insulin resistance; QUICKI, Quantitative Insulin Sensitivity Check Index; SHBG, sex hormone binding hormone.

CRP, we used the 25% quartile of CRP and CRP/albumin ratio as the cut-off point for both predictors.

Using the calculated cut-off values, regression analysis was performed to determine how well each variable predicted PCOS. To fully explore the role of the CRP/albumin ratio as a biomarker in the prediction of metabolic disturbances, CRP and CRP/albumin ratio were additionally assessed as binary variables. Subjects were categorised into two groups based on the cut-off values and their means (SD) for metabolic markers. IR (HOMA-IR), FT, total adiponectin, BMI and TSH were compared between subjects with normal values, and those who had higher than normal values. P values <0.05 were considered as statistically significant. All statistical analyses were performed using the IBM SPSS statistics software program V.22 (IBM).

RESULTS

Study subjects

The sociodemographic, anthropometric, clinical and biochemical characteristics of the 200 women with PCOS and 119 controls women are summarised in table 1. Relative to controls, women with PCOS had fewer pregnancies and live births ($p<0.001$), were more likely to have IR ($p<0.001$), and differed in education attainment with those with PCOS, having a higher number of high school and postsecondary graduates ($p=0.012$).

Metabolic characteristics

The proportion of women with a BMI greater than 30 kg/m^2 were higher in the PCOS cohort than controls ($p<0.001$), but the waist to hip ratio was not significantly different (table 1). Serum levels of adiponectin, an adipocyte-associated protein that tends to be inversely linked to visceral adiposity,²⁶ were markedly lower in women with PCOS compared with controls. Fasting plasma glucose, cholesterol, high-density lipoproteins (HDL), low-density lipoproteins (LDL) and triglyceride levels did not differ significantly between women with and without PCOS. However, indices of IR and insulin sensitivity (HOMA-IR and Quantitative Insulin Sensitivity Check Index) indicated that women with PCOS had greater impaired regulation of insulin compared with controls (table 1).

Reproductive hormone characteristics

There were no statistically significant differences in plasma levels of oestradiol, progesterone, total testosterone, prolactin, FSH, LH and DHEAS between women with and without PCOS. FT was higher and SHBG lower in women with PCOS (table 1).

CRP/albumin ratio stratified by BMI

Women with PCOS had markedly higher levels of CRP and lower levels of serum albumin relative to controls ($p<0.001$; table 1). ROC curve analysis showed that the CRP/albumin ratio had greater discriminatory power to differentiate between women with PCOS and controls

Figure 1 Receiver operating characteristic curve plotting the true positive rate against the false positive rate for CRP/albumin (blue line) and CRP (green line) in differentiating women with and without PCOS. The area under the curve for CRP/albumin: 0.865, 95% CI 0.824 to 0.905; for CRP 0.820, 95% CI 0.773 to 0.867. BMI, body mass index; CRP, C reactive protein; PCOS, polycystic ovary syndrome.

(AUC: 0.865, 95% CI 0.824 to 0.905) compared with CRP alone (AUC 0.820, 95% CI 0.773 to 0.867); figure 1. This greater efficacy of CRP/albumin ratio to discriminate between cases and controls was also evident when taking into account the presence of IR at every measure of sensitivity; for a sensitivity level of 75%, CRP/albumin ratio had a specificity of 85% compared with 69% for CRP alone.

Spearman correlation analysis between CRP/albumin ratios and clinical and biochemical markers was subsequently performed. Variables found to be univariately linked to CRP/albumin values were included in a general linear model testing the relationships among PCOS diagnosis, BMI and CRP/albumin levels. The model revealed that for any given BMI value, women with PCOS have markedly elevated CRP/albumin levels ($p<0.001$, figure 2).

Variables that are known to strongly associate with PCOS, namely Free Androgen Index and IR, were compared with CRP/albumin ratio as predictors of PCOS in a binary regression analysis stratified by three BMI categories: $<25\text{ kg/m}^2$ (normal), $25\text{--}30\text{ kg/m}^2$ (overweight), $>30\text{ kg/m}^2$ (obese); table 2. A CRP/albumin ratio of ≥ 0.097 outperformed both IR and Free Androgen Index in predicting PCOS for every BMI category (table 2).

DISCUSSION

This study demonstrates that CRP/albumin ratio is a stronger correlate of PCOS than both free androgens and IR in 319 ethnically matched premenopausal women, and

Figure 2 Linear regression analysis of adjusted CRP/albumin values by body mass index (BMI) in women with PCOS and controls. A univariate generalised linear model was computed investigating the relationship between CRP/albumin and BMI, adjusting for the variables found to associate with CRP/albumin (insulin, free testosterone, progesterone and adiponectin) plus age stratified by PCOS diagnosis. CRP, C reactive protein; PCOS, polycystic ovary syndrome; ROC, receiver operating characteristic.

this relationship was independent of BMI. Despite being the most common reproductive disorder to affect women, the aetiology of PCOS has remained elusive to date. In the absence of a definitive cure, treatment has focused on symptom management, and a goal to prevent the progression of serious health conditions, such as type 2 diabetes and CVD, for which women with PCOS are at heightened

risk. Chronic low-grade inflammation has emerged as a common underlying state in women with PCOS, and a likely direct contributor to IR and heart disease risk. This has raised the question whether PCOS is fundamentally an inflammatory condition.^{8 10 27}

Small sample sizes, heterogeneous populations and an inability to correct for confounding factors, such as BMI and use of oral contraceptives, both of which influence inflammatory markers such as CRP,²¹ has in part hampered efforts in assigning inflammation as truly a defining feature of PCOS. This current analysis has overcome some of the main issues in assessing the independent relationship between PCOS and chronic low-grade inflammation. This was accomplished by accounting for many of the confounding variables and by using a more refined marker for inflammation, the CRP/albumin ratio, which may have greater specificity and sensitivity for inflammation associated with metabolic dysfunction. The CRP/albumin ratio was first found to be useful in assessing cardiometabolic and inflammatory status following ovariectomy surgery.²⁰ It was subsequently used to show the influence of chronic subclinical inflammation on bone quality in women with PCOS.²¹ Although CRP is used to predict cardiovascular risk and is associated with metabolic disorders associated with obesity and IR,^{28–31} it has been criticised for being too general and non-specific a marker for inflammation.³²

When compared with CRP alone, we found that the CRP/albumin ratio has an improved ROC curve for predicting PCOS. Serum albumin, which is commonly measured to assess liver function and malnutrition, is not widely considered as an analyte of interest for PCOS. However, this study showed for the first time that albumin is markedly reduced in women with PCOS relative to controls. This may, at least in part, be due to albumin

Table 2 Summary of binary regression analysis for variables predicting PCOS with the OR of each risk factor adjusted for other variables in the model

	OR (95% CI)		
	BMI <25 kg/m ² (normal)	BMI 25–30 kg/m ² (overweight)	BMI ≥30 kg/m ² (obese)

CRP, C reactive protein; HOMA, homeostasis model assessment; PCOS, polycystic ovary syndrome.

being a negative acute phase protein.¹⁸ It is also possible that there is increased oxidation and glycation of albumin in women with PCOS, which can impact the structure, function and metabolism of the protein.¹⁸ Albumin is one of the most abundant serum proteins, and among its many roles is the transport of hormones.¹⁹ Thus, reduced albumin levels can potentially contribute to higher free androgens in women with PCOS and exacerbation of disease phenotype.

This analysis was limited by a lack of a more sensitive measure of visceral adiposity; the gold standard is imaging with CT or MRI.³³ Furthermore, the case-control design limited the ability to assess how CRP/albumin performs in predicting health outcomes in women with PCOS. Prospective studies are now needed to determine the use of CRP/albumin in predicting the progression of disorders linked to chronic inflammation and metabolic dysfunction that women with PCOS are at increased risk. These include CVD and diabetes, and depression.^{34–37} Importantly, CRP/albumin ratio may be particularly useful in assessing the effectiveness of new interventions targeting inflammation in women with PCOS as a novel approach to managing the condition and its long-term health consequences.

CONCLUSION

CRP/albumin ratio, a marker for inflammation related to metabolic dysfunction, was found to have a stronger association with PCOS than either androgen excess or IR. Inflammation is known to be influenced by adiposity, but relative to controls, women with PCOS have higher levels of CRP/albumin ratio irrespective of BMI. This supports the view that inflammation may play a central role in the pathophysiology of PCOS.
