ABSTRACT

Objective To assess the clinical effectiveness and safety of modified 'Huoxue Shugan' (HXSG) formulas used as Chinese herbal medicine in treating patients with coronary heart disease (CHD) and depression.

Methods A systematic literature search of articles up to March 2018 will be performed in the following electronic databases: PubMed, Embase, the Cochrane Library, China National Knowledge Infrastructure, Chinese Scientific Journals Database, Chinese Biomedical Database, Chinese Biomedical Literature Service System and Wanfang Database. Inclusion criteria are as follows: randomised controlled trials of modified HXSG formulas in patients with CHD and depression. The primary outcome measures will be CHD-related clinical evaluation (frequency of acute angina, severity of angina pectoris, ECG changes, dose of nitroglycerin) and the scores or amount of reduction in scales measuring depression (ie, the Hamilton Depression Scale or other widely used depression scales). The safety outcome measures will be adverse events, liver and kidney function. RevMan V.5.3 software will be used for data synthesis, sensitivity analyses, subgroup analyses and risk of bias assessment. A funnel plot will be developed to evaluate reporting bias. Stata V.12.0 will be used for meta-regression and Egger tests. We will use the Grading of Recommendations Assessment, Development and Evaluation system to assess the quality of evidence.

Ethics and dissemination This systematic review does not require ethics approval and will be submitted to a peer-reviewed journal.

PROSPERO registration number CRD42018089641.

INTRODUCTION

Coronary heart disease (CHD) has remained one of the most serious diseases; it has high mortality and morbidity and is the leading cause of death worldwide.¹ Depression has been another concerning mental health problem, leading to serious disability, and has largely contributed to the overall global burden of disease.² It has been widely reported that depression can aggravate CHD-related angina symptoms and lead to an adverse CHD prognosis. Conversely, CHD

Strengths and limitations of this study

- This study is an objective and normative systematic review evaluating the effectiveness and safety of modified 'Huoxue Shugan' formulas used as Chinese herbal medicine in the treatment of patients with coronary heart disease and depression.
- Study screening, data extraction and assessment of the risk of bias will be independently conducted by two researchers.
- Disagreements will be resolved by discussion or arbitrated by a third author if needed.
- There may be clinical heterogeneity because of variations in treatment frequency or duration, or other factors. Therefore, subgroup analyses or meta-regression analyses will be carried out to explore any source of heterogeneity.
- The Grading of Recommendations Assessment, Development and Evaluation system will be used to further evaluate study findings.
- Because this is a retrospective meta-analysis, the search has the inevitable potential of excluding unpublished trials which will introduce some bias.

has also been shown to aggravate depressive symptoms.³ In the population of patients with CHD, depression has not only been linked to a twofold increase in the risk of death and a higher risk for major adverse cardiac events but has also been shown to diminish long-term quality of life.⁴⁻⁶ According to one study, approximately 40% of patients with CHD have comorbid depression and represent the major group experiencing worse physical health outcomes associated with CHD when compared with similar patients with CHD but without depression.⁷

Because of the association between CHD and depression, CHD basic treatment and antidepressant therapy have always been administered in parallel in the clinical arena. However, the side effects of antidepressants

has limited their use overall in the long-term treatment of patients with depression.⁸

Chinese herbal medicine (CHM) has been used clinically as therapy treatment for thousands of years. Currently, CHM is commonly and widely used as alternative therapy for the management of CHD and depression in China. There is increasing evidence that therapy with CHM has emerged as a potentially promising therapeutic measure for patients with CHD and depression.^{9–11} Previous studies have demonstrated that ‘Huoxue’ formulas play a significant role in relieving angina pectoris and improving ECG results in patients with CHD.^{12–14} Moreover, ‘Shugan’ formulas, which have been used most commonly in depressed patients, have been shown to significantly improve depressive symptoms.^{15 16} Among a variety of CHM therapies, modified ‘Huoxue Shugan’ (HXSG) formulas have been employed in clinical medicine most commonly in patients with CHD and depression.^{9 17}

Despite numerous previous clinical studies and reviews evaluating CHM therapies in the treatment of patients with CHD and depression, systematic reviews to assess the effectiveness and safety of different HXSG formulas in this patient population are rare. We identified only one meta-analysis evaluating the effectiveness of CHM therapies in patients with CHD and depression, though the study had certain limitations.⁸ There were 13 randomised clinical trials (RCTs) included in the meta-analysis by Wang *et al.*⁸ However, the CHM therapies studied were both dissimilar and complex; there was heterogeneity among the interventions, and the outcomes of the CHD-related clinical evaluations were relatively incomplete.

In view of the shortcomings of previous studies and the insufficient evidence regarding the widespread use of HXSG formulas, this systematic review aimed to summarise the effectiveness and safety of modified HXSG formulas, one of the important CHM therapies, in treating patients with CHD and depression.

METHODS AND ANALYSIS

Registration

The study protocol has been registered in the international prospective register of systematic review (PROSPERO). The procedure of this protocol will be conducted according to the Preferred Reporting Item for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P) guidelines.¹⁸

Eligibility criteria

Type of study

Inclusion

We will include all the RCTs that investigated the effectiveness and safety of modified HXSG formulas combined with pharmacotherapy for the treatment of patients with CHD and depression.

Exclusion

The studies will be excluded if it is not an RCT (namely, observational cohort and case-control studies, case reports, experimental studies and reviews).

Participants

Inclusion

The study will include patients diagnosed simultaneously with both CHD and depression regardless of age, sex, ethnicity, education or economic status and whether or not they were outpatients or inpatients. The diagnostic criteria for CHD and depression will be as follows^{19–21}:

1. The diagnostic criteria of CHD should be confirmed according to one of the past or current definitions: Report of the Joint International Society and Federation of Cardiology/WHO task force on standardisation of clinical nomenclature of ischaemic heart disease, or the American College of Cardiology/American Heart Association guideline update for the management of patients with chronic stable angina or Chinese Association of Cardiology or unstable angina pectoris diagnosis and treatment recommendations.^{22–24}
2. Depression must be defined as a depressive disorder or clinical depression diagnosed according to the Diagnostic and Statistical Manual of Mental Disorders, the International Classification of Diseases by a standardised interview (eg, Structured Clinical Interview, Composite International Diagnostic Interview) or the Chinese Classification of Mental Disorders.

Exclusion

Patients with either CHD or depression only will be excluded. Patients with severe respiratory disease, acute infectious disease, severe heart disease, severe liver disease or tumours will be excluded.

Interventions

Inclusion

Eligible interventions will be those involving a combination of modified HXSG formulas and conventional pharmacotherapy. The same conventional pharmacotherapy must be used in the control group.

Exclusion

Trials that include other cointerventions such as another herbal formula, acupuncture, cupping, moxibustion, massage, yoga, qigong, Tai Chi or aromatherapy will be excluded.

Outcome

Inclusion

The primary outcome measures will include the following: CHD-related clinical evaluation (frequency of acute angina, severity of angina pectoris, ECG changes, dose of nitroglycerin), the scores or reduction in scales measuring depression (ie, the Hamilton Depression Scale or other widely used depression scale).²⁵ The secondary outcome measures will include the following: total cholesterol, triglyceride, low-density lipoprotein

cholesterol and high-density lipoprotein cholesterol levels and the Traditional Chinese Medicine syndrome scale. The safety outcomes will include the following: adverse events (such as digestive symptoms, headache, dizziness, skin rash, etc), liver or kidney toxicity measured by serum markers.

Exclusion

The outcome measures not requested in this study will be excluded.

Search strategy

The following electronic bibliographic databases will be searched from inception to March 2018: PubMed, Embase, the Cochrane Library, China National Knowledge Infrastructure, Chinese Scientific Journals Database, Chinese Biomedical Database, Chinese Biomedical Literature Service System and Wanfang Database. A manual search of key journals and of the reference lists of reviews captured by the initial searches will also be performed. There will be no limits on the language of publication. Only clinical trials will be included and searched. The following sources will also be searched to identify clinical trials that are in progress or completed: Clinical Trials.gov and WHO clinical trials registry. Any additional relevant studies will also be retrieved from the reference lists of systematic reviews and included studies. If possible, we will map search terms to controlled vocabulary. In addition, the search strategy for selecting the fields of title, abstract or keyword will differ depending on the characteristics of the databases. Search terms will be grouped into three blocks (see [table 1](#)).

Study selection and data extraction

Literature-retrieved citations will be managed by EndNote X7 software. Two authors (MC and ML) will independently screen the titles and abstracts of all the studies retrieved in the above electronic databases to identify potentially eligible studies. Articles that are duplicated or have not met the eligibility criteria, interventions and outcomes in this study will be excluded. After filtering the final eligible articles, the data from the included articles will be extracted independently by two authors (MC and ML). Disagreements will be resolved by discussion or arbitrated by a third author if needed (LM or ZZ). The following categories of data will be extracted: first author, publication year, diagnose information, age, sex, trial characteristics, interventions and controls, participants, study methodology, outcomes and adverse events (see [figure 1](#)).

Risk of bias assessment

The methodological quality of the eligible studies will be evaluated according to the Cochrane Collaboration's tool for assessing risk of bias.²⁶ The assessment details include: sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessors, incomplete outcome data, selective reporting and other sources of bias. Each domain will be assessed as 'low risk', 'high risk' or 'unclear risk' according to the description details of eligible studies.

Data synthesis and statistical analysis

Statistical analyses will be conducted with RevMan V.5.3 software provided by Cochrane Collaboration. The

overall effect sizes will be determined as the mean difference for continuous outcomes, the OR for dichotomous outcomes with their 95% credible intervals. The Q and I^2 test statistics will be calculated to determine the amount of heterogeneity. For the Q statistic, $p < 0.05$ will be considered to indicate significant differences. For the I^2 statistic, $I^2 < 25\%$ indicates no significant heterogeneity, $I^2 = 25\% - 50\%$ is considered moderate heterogeneity and $I^2 > 50\%$ indicates strong heterogeneity. We will use fixed effects models if there is no heterogeneity among studies, and random effects models if there is heterogeneity.

Sensitivity analysis, subgroup analysis and meta-regression

If the heterogeneity or inconsistency among the studies is detected, a sensitivity analysis or subgroup analysis or meta-regression (conducted by Stata V.12.0) analysis will be performed. Subgroup analysis will be conducted to explore potential sources of heterogeneity according to the characteristics of studies, including sample size, types

of CHD, severity of depression, dose of HXSG formulas, treatment duration and other relevant parameters. If data extraction is insufficient, we will create a qualitative synthesis.

Publication bias

A funnel plot will be developed to evaluate reporting bias of the included studies. We will use Egger tests (conducted using Stata V.12.0) to assess funnel plot symmetry and will interpret values of $p < 0.1$ as statistically significant.

Quality of evidence

We will also assess the quality of evidence for the main outcomes with the Grading of Recommendations Assessment, Development and Evaluation approach. Five items will be investigated, including limitations in study design, inconsistency, inaccuracies, indirectness and publication bias.

Patient and public involvement

The patients and/or public will not be involved because this study uses secondary sources for analysis.

DISCUSSION

We plan to conduct this meta-analysis to evaluate the effectiveness and safety of HXSG formulas for patients with CHD and depression. However, there may be some limitations because this is a retrospective meta-analysis. First, during the search, there is the inevitable potential that unpublished studies will not be identified which will introduce some bias. Moreover, some grey literature may be difficult to retrieve, possibly leading to a selection bias in the literature. In addition, some secondary outcome measures may not be completely reported. Nevertheless, we expect that the results of this study will be able to propose clinical recommendations for patients with CHD and depression in clinical practices that employ CHM and provide more reliable evidence supporting use of the latter.

Ethics and dissemination

The results of the meta-analysis will be reported according to the PRISMA extension statement and disseminated in a peer-reviewed journal.
