Efficacy and safety of the pulsed electromagnetic field in osteoarthritis: a meta-analysis

Ziying Wu, Xiang Ding, Guanghua Lei, Chao Zeng, Jie Wei, Jiatian Li, Hui Li, Tuo Yang, Yang Cui, Yilin Xiong, Yilun Wang, Dongxing Xie

ABSTRACT

Objective To investigate the efficacy and safety of the pulsed electromagnetic field (PEMF) therapy in treating osteoarthritis (OA).

Design Meta-analysis.

Data sources PubMed, Embase, the Cochrane Library and Web of Science were searched through 13 October 2017.

Eligibility criteria for selecting studies Randomised controlled trials compared the efficacy of PEMF therapy with sham control in patients with OA.

Data extraction and synthesis Pain, function, adverse effects and characteristics of participants were extracted.

Results Twelve trials were included, among which ten trials involved knee OA, two involved cervical OA and one involved hand OA. The PEMF group showed more significant pain alleviation than the sham group in knee OA (standardised mean differences (SMD)=−0.54, 95%CI −1.04 to −0.04, p=0.03) and hand OA (SMD=−2.85, 95%CI −3.65 to −2.04, p<0.00001), but not in cervical OA. Similarly, comparing with the sham–control treatment, significant function improvement was observed in the PEMF group in both knee and hand OA patients (SMD=−0.34, 95%CI −0.53 to −0.14, p=0.0006, and SMD=−1.49, 95%CI −2.12 to −0.86, p<0.00001, respectively), but not in patients with cervical OA.

Conclusions PEMF could alleviate pain and improve physical function for patients with knee and hand OA, but not for patients with cervical OA. Meanwhile, a short PEMF treatment duration (within 30 min) may achieve more favourable efficacy. However, given the limited number of study available in hand and cervical OA, the implication of this conclusion should be cautious for hand and cervical OA.

INTRODUCTION

Osteoarthritis (OA) is a widespread degenerative disease, which can lead to pain, physical dysfunction and even disability. The joints most commonly affected by OA include knees, hips, hands, neck and feet. A variety of medications and physical therapies have been used in the treatment of OA. However, some widely applied drugs (eg, chondroitin, glucosamine, intra-articular hyaluronic acid, etc) or physical treatments (eg, transcutaneous electrical nerve stimulation and ultrasound) are actually not advocated by the recent Osteoarthritis Research Society International guidelines. To date, few effective treatments for knee OA are available.

Since the early 1980s, researchers have found that pulsed electromagnetic field (PEMF) therapy could be applied to accelerate wound healing, repair fracture, reduce haematoma and treat soft tissue injury and inflammation. In addition, some studies have demonstrated that PEMF could activate the signal transduction pathway and induce the human articular chondrocyte proliferation. Being a simple, non-invasive and safe physical therapy, PEMF was considered to be an alternative treatment regimen for OA. During the past two decades, more than 10 randomised controlled trials (RCTs) were conducted to explore the efficacy of PEMF in the treatment of OA, but no consensus was reached yet. Several previous meta-analyses have evaluated

Strengths and limitations of this study

- This study provided a comprehensive assessment on the efficacy and safety of the pulsed electromagnetic field (PEMF) therapy in patients with knee, hand and cervical osteoarthritis (OA).
- All included studies in this meta-analysis were randomised controlled trials.
- There was a high level of heterogeneity among various studies, because different treatment protocols of PEMF were used in the included studies.
- There were sparse eligible trials available for the efficacy analysis of hand OA and cervical OA, and the reliability of the conclusions on these two joints were limited.
the combined effects of PEMF and pulsed electrical stimulation (PES) on OA. However, the mechanisms of PEMF and PES were totally different. For example, PES is delivered through capacitive coupling using transcutaneous electrodes and coupling agents relying on the direct application of an electrical field, whereas PEMF creates induced current through magnetic impulse. To the best of our knowledge, few meta-analyses have evaluated the efficacy and safety of single PEMF for OA.

To fill in this knowledge gap, the purpose of the present study was to provide a comprehensive assessment on the efficacy and safety of single PEMF in patients with OA at different joints. It was hypothesised that PEMF could relieve pain and improve the physical function of patients with OA without producing side effects.

METHODS

Search strategies and studies selection

The study records were identified in four electronic databases of PubMed, Embase, the Cochrane Library and Web of Science through using the combination of a series of keywords and text terms describing OA and PEMF (see online supplementary appendix 1). The latest literature search was conducted on 13 October 2017. Studies were included if: (1) subjects had symptomatic or radiographic OA, (2) the intervention contained PEMF versus sham-control, (3) the study was designed as an RCT, (4) the primary outcome included pain and/or function. Studies were excluded if: (1) experimental studies (eg, in vitro studies, animal studies or cadaveric studies), (2) studies for postoperation rehabilitation, (3) subjects treated by short wave or PES or any other physical therapies, (4) studies cannot get full text, (5) studies no data available, (6) unbalanced additional non-pharmacological treatments (eg, exercise or hot pack) between groups.

Quality assessment

The methodological quality of each included trial was evaluated by two independent authors based on the Cochrane handbook, which consists of seven domains: generation of randomisation sequences, allocation concealment, blinding of participants and implementers, blinding of outcome assessment, incomplete outcome data, selective reporting and other potential biases. Furthermore, any of divergence was to be discussed and a third consultant

Figure 1  Flow chart of studies screening process based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guideline.
was needed if necessary.28 29 Trials involving three or more high risks of bias were considered as poor methodological quality.30

Data extraction and outcome measure
All the data were extracted by two independent authors. The extracted information included the characteristics of participants (age, gender, body mass index and duration of OA), balance intervention between groups, number of participants in each trial, treatment protocol of PEMF and the type of outcome measures, baseline data, post-treatment data and mean changes and SD or the information from which SD could be derived, such as SE or CI. The primary goal of this study was to assess the efficacy of pain alleviation and function improvement by applying the PEMF therapy for patients with OA. Adverse events (AEs) were considered as the safety outcome. The efficacy of pain alleviation was measured by change of pain intensity from baseline.31 Data at the last follow-up time point after treatment were extracted to calculate the change degree from baseline to the last follow-up. According to the recommended hierarchy of continuous pain-related outcomes used in the meta-analyses,32 33 the outcome data expressed in higher ranking scale were extracted if multiple pain scale measured simultaneously. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) function was the preferred measure for function outcome. If a study did not measure or report the WOMAC function, WOMAC total, Short Form-36 Health Survey (SF-36) social function score or total score and physician global assessment scores were used in the analysis instead.34 The number of participants who reported AEs were also extracted in order to evaluate the safety of interventions.

Statistical analysis
The Review Manager V.5.2 was used to perform all the statistical analyses. As the outcome of pain and function reported by continuous data and various scales were used for outcome assessment, the standardised mean differences (SMDs) were calculated to compare the effect of pain alleviation and function improvement between different intervention groups. For the safety outcome, the relative risk (RR) was calculated to compare the safety between the two groups. Trials that reported zero AE in both the PEMF and the sham groups were not included in the AEs analysis.26 Ninety-five per cent CI was calculated for pooled estimates for each outcome. Statistical significance was considered at p<0.05. A random model was applied to pool the data. Q and I² statistics were calculated to assess the heterogeneity among the included studies, with a p value >0.05 of the Q statistics and I² value <50% indicating statistical homogeneity. It is hypothesised that different exposure duration of PEMF and disease location will influence treatment effect. Therefore, subgroup analyses were performed according to the exposure duration of PEMF therapy (no more than 30 min per session or more than 30 min per session)5–7 and location of OA. Funnel plots were inspected to assess publication bias.

Patient and public involvement
No patients or members of public were involved in the present study. No patients were asked to advise on the interpretation or writing up of results. The results of the

present research will be communicated to the relevant patient community.

RESULTS
Study screening and characteristics of included studies
Figure 1 showed the flow diagram for study screening. One hundred and ninety-two records were identified initially and 12 studies9–20 met the eligibility criteria and were included in this meta-analysis. The characteristics of included studies are summarised in table 1. The risk of bias assessment (figure 2) showed that one study9 was regarded as low quality.

Pain relief
Twelve RCTs were included for meta-analysis of pain management.9–20 As shown in figure 3, PEMF group achieved a significant difference in pain improvement compared with the sham group (SMD=−0.94, 95% CI −1.49 to −0.39, p=0.0008), while significant heterogeneity was observed (I²=92%; p=0.00001). Subgroup analysis showed that significant differences were observed between the PEMF and sham group on pain improvement in patients with knee OA (SMD=−0.54, 95% CI −1.04 to −0.04, p=0.03) and hand OA (SMD=−2.85, 95% CI −3.65 to −2.04, p<0.0001), whereas no significant difference was achieved between groups in patients with cervical OA (p=0.25).

Function improvement
Eight RCTs were included for meta-analysis of physical function improvement.9 10 12 13 15 16 19 20 Figure 4 illustrated the beneficial effect of PEMF on physical function improvement (SMD=−0.45, 95% CI −0.71 to −0.19, p=0.0005), and substantial heterogeneity was observed (I²=54%; p=0.03). However, the subgroup analysis of different OA locations suggested significant differences both in knee OA and hand OA (SMD=−0.34, 95% CI −0.53 to −0.14, p=0.0006, and SMD=−1.49, 95% CI −2.12

### Pain
- **Location**
  - Knee OA: -0.54 (-1.04 to 0.04), 88%, 0.03
  - Cervical OA: -2.33 (-6.26 to 1.61), 97%, 0.25
  - Hand OA: -2.85 (-3.65 to 2.04), NA, <0.00001

- **Exposure duration**
  - No more than 0.5 hour/session: -1.01 (-1.64 to 0.39), 91%, 0.001
  - More than 0.5 hour/session: -0.61 (-2.25 to 1.02), 95%, 0.46

### Function
- **Location**
  - Knee OA: -0.34 (-0.53, 0.14), 0%, 0.0006
  - Cervical OA: -0.27 (-0.71 to 0.16), NA, 0.22
  - Hand OA: -1.49 (-2.12 to 0.86), NA, <0.00001

- **Exposure duration**
  - No more than 0.5 hour/session: -0.50 (-0.81 to 0.18), 59%, 0.002
  - More than 0.5 hour/session: -0.33 (-0.82 to 0.17), 54%, 0.20

### Adverse event
- **Exposure duration**
  - No more than 0.5 hour/session: 0.42 (0.14 to 1.29), 0%, 0.13
  - More than 0.5 hour/session: 1.95 (0.81 to 4.71), NA, 0.14

NA, not available.; OA, osteoarthritis; RR, relative risk; SMD, standard mean difference.

Figure 4  Forest plot of pulsed electromagnetic field (PEMF) compared with sham–control on function. There were significant differences both in knee osteoarthritis (OA) (p=0.0006) and hand OA (p<0.00001), whereas there was no significant difference between groups in patients with cervical OA (p=0.22).
to –0.86, p<0.00001, respectively, see table 2), whereas there was no significant difference between groups in patients with cervical OA (SMD=–0.27, 95% CI –0.71 to 0.16, p=0.22). In addition, there was a significant difference on effect of function improvement with exposure duration within 30 min (SMD=–0.50, 95% CI –0.81 to 0.18, p=0.002), and no significant difference was observed in more than 30 min group (SMD=–0.33, 95% CI –0.82 to 0.17, p=0.20). Funnel plot also did not identify substantial asymmetry.

Adverse events
There were 10 RCTs that reported AEs.9–11 13 14 16–20 Seven of them claimed that no AEs were observed both in PEMF and sham group.9 10 13 14 17 18 20 Three trials reported the AEs of each treatment group, which mainly included increased knee pain, hip pain, spine pain, vomiting, warming sensation, increased blood pressure, numbness of feet, paraesthesia of foot and cardiomyopathy, and there were no AE-related dropouts in each trial.11 16 19 There was no significant difference between the PEMF and the sham group regarding AEs (RR=0.83, 95% CI 0.26 to 2.64, p=0.75) (figure 5). Substantial asymmetry was not identified in the funnel plot.

DISCUSSION
This study provided a comprehensive assessment of the scientific literature on the efficacy and safety of the PEMF therapy in patients with knee, hand and cervical OA. The results showed that, in comparison with the sham–control group, PEMF was more effective in both pain relief and function improvement for patients with knee OA and hand OA, but not for patients with cervical OA. The poor efficacy of the treatment for cervical OA may be due to the anatomical factors of cervical spine. The neurovascular structures contained in the cervical spinal canal may be compressed due to cervical OA, which will then induce a series of symptoms, such as the upper limb nerve root pain induced by nerve root compression, the chronic vertebral and basilar arterial insufficiency due to compression of vertebral arteries and the numbness of limbs and easiness to falling caused by spinal cord compression.39–40 Although some studies showed that PEMF could enhance articular cartilage regeneration,41 42 no evidence yet demonstrated that PEMF can reduce osteophytes formation, which may induce nerve root compression that can lead to deterioration of pain and function. In addition, the limited number of studies available is another reason that should not be ignored.

Figure 5 Forest plot of pulsed electromagnetic field (PEMF) compared with sham–control on adverse events. There was no significant difference between the PEMF and the sham group regarding adverse events (p=0.75).
The present study further examined the association between the exposure duration of PEMF and efficacy for patients with OA. The results suggested that the exposure duration (≤30 min per session) could achieve better efficacy both in pain relief and function improvement. The reason could be explained by several previous laboratory studies. A recent study exploring the effects of different PEMF treatment durations (ranged from 5 to 60 min) over the mesenchymal stem cell (MSC) chondrogenic differentiation reported that the expression of MSC chondrogenic markers showed the greatest increase in response to 5–20 min PEMF treatment.43–45 Similarly, another two studies which have shown that PEMF could activate cellular signaling transduction rapidly within 5–10 min, whereas the signaling might be largely dulled after 30 min.5,7

Nevertheless, limitations of the present study should be acknowledged. First, since different treatment protocols of PEMF were used in the included studies, there was a high level of heterogeneity among various studies. Second, there were sparse eligible trials available for the efficacy analysis of hand OA and cervical OA, and the accuracy of the conclusions on these two joints were limited. In addition, because the number of studies reporting the pulse frequency of application, pulse intensity, pulsed rate and other parameters of PEMF was very limited, subgroup analyses were restricted according to these parameters of PEMF. Finally, morphological change is a meaningful outcome for exploring the treatment efficacy of PEMF further46, however, the morphological changes were not reported in the present study due to the lack of relevant data. More trials are needed to evaluate the morphological changes after PEMF therapy.

CONCLUSION

The present study revealed that PEMF could alleviate pain and improve physical function for knee and hand OA patients, but not for cervical OA. Meanwhile, a short PEMF treatment duration (within 30 min) may achieve more favourable efficacy. However, given the limited number of studies available in hand and cervical OA, the implication of this conclusion should be cautious for hand and cervical OA.
