ABSTRACT

Introduction Although recurrence rate among cases of resected pancreatic cancer are as high as 85%, an optimal treatment for recurrent pancreatic cancer (RePC) has not been established. Previous evidence regarding RePC is scarce, and randomised controlled trials (RCTs) are particularly lacking. The evidence mapping (EM) method has been introduced as a tool intended to complement the conventional systematic review (SR) and meta-analysis (MA) and is suitable for this issue. This review aims to investigate the optimal treatment options for RePC, using a newly developed automatic EM tool.

Method and analysis All study types, including RCTs, non-randomised studies and other forms of observational studies will be included in the SR-EM. The Medline, Embase, Cochrane library and Scopus databases will be searched for reports of five treatment options for local and metastatic recurrences, including re-resection, chemotherapy, radiotherapy, best supportive care and other novel treatments, published from database inception to 30 April 2017. References from relevant studies will be searched manually. If meta-analysis is feasible, the primary outcome measure will be median overall survival. Two independent authors will select the studies and assess the risk of bias, and a third author will resolve discrepancies in consensus meeting. To visualise EM, we will use a novel web-based and open-access mapping programme, Plotting E-Map (PLOEM) (<http://plotting-e-map.com>). If eligible combinations of interventions for quantitative comparison are identified, we will conduct subgroup MAs using random-effect models and I² statistics. Publication bias will be visualised using funnel plots.

Ethics and dissemination This study will not use primary data, and therefore formal ethical approval is not required. The findings will be disseminated through peer-reviewed journals and committee conferences.

PROSPERO registration number CRD42016049178.

INTRODUCTION

Description of condition

Pancreatic cancer is the fourth and fifth leading cause of cancer-related deaths in the USA and Europe, respectively.^{1 2} The 5-year

Strengths and limitations of this study

- This is the first systemic review of treatments for recurrent pancreatic cancer after surgical resection.
- To perform evidence mapping (EM) for multiple treatment options, we established a novel automatic web-based programme, Plotting E-Map (PLOEM) (www.plotting-e-map.com).
- The scope of this study encompasses both local and metastatic recurrences and five types of treatment: re-resection, chemotherapy, radiotherapy, best supportive care and other novel treatments.
- We distinct the concepts of 'evidence gap map' and 'EM'.
- Our study is limited by the lack of a well-designed randomised controlled trial of this condition.

survival rate of pancreatic cancer remains near 7% and has not significantly improved in several decades.^{1 2} As pancreatic cancer is difficult to detect in early stages, only approximately 20% of patients with pancreatic cancer are candidates for curative resection during the first diagnostic phase.³ Even more unfortunately, the recurrence rate of pancreatic cancer is as high as 85%, even after curative resection.^{4 5}

Recurrent pancreatic cancers (RePCs) manifest in one of two patterns: locoregional or metastatic recurrence.⁶ One retrospective observational study reported that the rates of local, metastatic and synchronous local/metastatic RePCs were 17%, 60% and 23%, respectively.⁷ Although the median overall survival (OS) after the first resection was 18.7 months in that study, the recurrence patterns did not affect OS. We note that the metastatic recurrence rate was higher than the local recurrence rate in that study; however, our pilot search found that treatment evidences for metastatic RePC were scarcer than for local RePC.

Table 1 Abbreviations

Abbreviations*	Full terms
BSC	Best supportive care
CRT	Chemoradiation therapy

RCT	Randomised-controlled trial
ReOP	Reoperation (ie, re-resection)
RePC	Recurrent pancreatic cancer
SC	Supportive care
SR	Systematic review

*In alphabetical order.

Description of the intervention

According to our pilot search, RePC treatment options could be categorised into five groups: re-resection (ReOP), systemic chemotherapy, radiation therapy, best supportive care (BSC) and other novel treatments (ONT). The abbreviations are listed in [table 1](#).

ReOP is defined as the surgical resection of a recurrent pancreatic cancer mass for curative purposes, with or without subsequent chemotherapy, and includes locally recurred tumourectomy, total pancreatectomy, metastasectomy and combinations of these operations. In 1975, Ellis *et al* first reported the second-look operation for RePC, a palliative gastrojejunostomy for gastric outlet obstruction but not a curative ReOP.⁸ The first retrospective study of curative ReOP was performed by Nakeeb *et al* in 1995 and included 27 patients who underwent pancreaticoduodenectomy.⁹ Since then, studies of ReOP with various designs have been conducted,^{10–12} but no randomised controlled trials (RCTs) had been published at the time of our pilot screening.

Chemotherapy indicates systematic chemotherapy for local or metastatic RePC without curative ReOP or concurrent chemoradiation therapy. Since the first report of quadruple chemotherapy in recurrent gastrointestinal carcinoma by Cheng *et al* in 1977,¹³ studies of RePC in diverse settings have been introduced and have mainly addressed gemcitabine-based regimens.^{14–16} Although several abstracts from medical conferences and small studies reported the use of other regimens, such as modified FOLFIRINOX or monoclonal antibodies, for RePC,^{17 18} few RCTs have used regimens other than gemcitabine according to our pilot search.

Radiotherapy includes both ‘radiation only’ and chemoradiation therapy (CRT, also called concurrent chemoradiation therapy) with a curative aim. Although most curative radiation treatments for pancreatic cancer

involve CRT, in which the chemotherapeutic agent is used for radiosensitisation,¹⁹ we also include ‘radiation only’ treatment because early studies (ie, before 1990s) reported radiotherapy without chemotherapeutic agents.^{20 21} From a technical viewpoint, radiotherapy includes conventional external beam radiation therapy, stereotactic body radiation therapy, intensity-modulated radiation therapy and intraoperative radiotherapy.²²

Unlike other treatment options, BSC has been inconsistently defined among various clinical trials and has been used interchangeably with ‘supportive care (SC)’.^{23 24} Whereas the definition of ‘palliative care’ is relatively homogenous,^{25 26} the definitions of BSC vary widely.²⁷ Because the present review focuses on ‘survival’ rather than on the BSC modality itself, we will not use a strict or narrow definition of BSC. Rather, we will accept each original article’s definition of BSC/SC and will tabulate each definition in the online supplementary materials.

ONT is another highly heterogeneous RePC treatment category. It includes all treatment options not included in the ReOP, chemotherapy, radiotherapy and BSC categories. According to our pilot search, ONT includes cryoablation, vaccine therapy, partial pancreatic autotransplantation and proton therapy.^{28–31} These heterogeneous treatment modalities could not be classified into a single group in a conventional meta-analysis (MA). However, the present study will use an ‘evidence mapping’ (EM) tool, thus allowing us to ‘map’ time trends or detailed information about these various modalities.³² We will include this ONT group only for mapping and not for quantitative analysis.

Controversy regarding treatment of RePC

Clinically, recent European (European Society for Medical Oncology) and US (American Society of Clinical Oncology) guidelines did not include treatment recommendations for RePC.^{33–36} Only the US National Comprehensive Cancer Network (NCCN) guideline suggests multiple treatment options, such as clinical trials (CRT) (for CRT-naïve cases), systemic chemotherapy or BSC, for RePC patients.⁶ The current NCCN guideline states that for selected cases with a good performance status and favourable tumour location, surgical resection may be considered but is not recommended due to lack of evidence.⁶ Only one study of pulmonary metastasectomy, by Arnaoutakis *et al*, reported a survival gain in patients with isolated lung metastases of pancreatic cancer,³⁷ and this is not firm evidence.

Methodologically, it is very difficult to evaluate the small amount of scattered evidence regarding issues related to RePC when using conventional systematic review (SR) and MA methods. Moreover, a networking process is needed because more than two treatment modalities exist. EM could be useful in this setting; however, no tool for EM has been established or standardised.³² In summary, the following major questions regarding the treatment of RePC have been raised: (1) which treatment modality is

optimal for RePC patients and (2) how can we evaluate the existing scattered, limited and multiarmed evidence using EM.

Importance of this work

First, this is the initial attempt to 'map' entire types of evidence regarding the treatment of RePC, from case reports to RCTs. When sufficient bodies of evidence exist, such as double-armed RCTs, conventional SR and MA methods may be able to provide quantitative conclusions. However, an alternative or complementary modality to SR is needed for settings that include multiple, heterogeneous, small-sized and scattered bodies of evidence. We will therefore adopt the EM method to perform this task. We expect that our work will help both clinicians who facing clinical decisions regarding RePC and researchers who plan to conduct prospective trials of RePC treatment.

Second, we established a novel EM tool, Plotting E-map (PLOEM), which has already been launched on an open-access website³⁸ and disseminated at an international conference during an oral presentation.³⁹ Using this automatic device, users can easily visualise the evidence related to their issue of interest, including the study types, study numbers, time factors and all options for multiple interventions. We expect that this open-access device will help researchers planning EM for any type of medical or public health issue. We will examine PLOEM in detail in the Discussion section.

Third, if possible, we will conduct MAs of the eligible combinations of treatment options as subgroup analyses. If existing unfounded evidence can be pooled into an analysis, this review will provide quantitative evidence

using subgroup MAs. As decisions regarding the ability to perform MAs will be made after the final EM process, this study may be described as a SR-EM or SR-EM-MA during the main article phase. Accordingly, we have set the title as SR-EM-MA during this protocol phase.

OBJECTIVES

Main objectives

This SR-EM-MA aims to visualise and structuralise the trends and efficacies of the five treatment options, including ReOP, chemotherapy, radiotherapy, BSC and ONT for RePC after curative resection, using the novel automatic mapping device PLOEM.

Secondary objectives

1. To develop and launch a novel EM device, PLOEM V.2.0;
2. To explore the trends of RePC treatment by several era, based on important points including introductions of new chemotherapeutic regimens or new OP techniques;
3. If possible, to conduct the meta-analyses or network meta-analyses in the eligible comparative studies after checking the feasibility of the quantitative meta-analyses.

METHODS AND ANALYSIS

Because this study is an SR, it will be performed according to the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement

Figure 1 PRISMA flowchart. PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses .

Table 2 Study types

(figure 1).⁴⁰ However, no official standard methodology has been developed for an EM.^{32 41–44} Therefore, we aim to develop a new set of reporting items for EM. The details of these new items will be mentioned in the Discussion section. A review protocol for this study has been published in the International Prospective Register of Systematic Reviews under registration number CRD 42016049178.

CRITERIA FOR STUDY CONSIDERATION IN THIS REVIEW

Types of studies

Because this SR primarily aimed to map trends, we will use the 'all times, all types' strategy. In this context, we will include almost all kinds of study designs such as case reports, case series, cross-sectional (descriptive and analytical) studies, case-control (retrospective and prospective, ie, nested case-control and case-cohort studies), cohort studies (retrospective and prospective) and clinical or experimental trials (randomised and non-randomised studies). To visualise and structuralise these designs intuitively, we reclassified and summarised all the study types in table 2. To distinguish between case series and cohort studies, we will follow the definition of Methes *et al*⁴⁵ and Dekkers *et al*⁴⁶

Participants

Participants in this review will be 18 years of age or older, diagnosed with RePC after curative surgical resection for primary pancreatic cancer. Because answers to the question of 'how many months after resection should be defined as a recurrence?' vary among the previous studies, we will not define recurrence according to a specific period of time. Instead, we will define a RePC as a new case of pancreatic cancer that was not identified during the first postoperative imaging exam. Pathologically, we will include only pancreatic ductal adenocarcinomas. We

will classify RePC cases as local or metastatic recurrence. If both groups are included in a single study, these will also be pooled and analysed separately.

According to study design, we will not exclude any kinds of studies basically, because this review aims to comprehensively map all treatment options for RePC. If a study includes a diverse population and the ductal adenocarcinoma is only a part of the study, we will ask the author for the original data. If this is not feasible, we will include the study only in visual mapping (EM), but we will exclude it from quantitative analysis of efficacy or toxicity.

In terms of population composition, we will exclude following studies: studies for (1) patients with pancreatic tumours other than ductal adenocarcinoma, (2) patients who have previously undergone initial pancreatic surgery with a palliative or explorative rather than curative aim and (3) patients who had remnant pancreatic cancer after surgery or incomplete resection.

Interventions and comparators

Whereas conventional MAs compare one intervention with one control, in our study, each of the five treatment options serves as both an intervention and a control of each other.

ReOP includes only curative resection, which encompasses remnant tumourectomy, pancreatectomy for locoregional recurrence or metastatectomy for remote recurrence. Chemotherapy includes any type of regimen for pancreatic cancer treatment. Chemotherapy will be pooled and visualised into a mapping tool regardless of the type of regimen, but detailed information about each regimen will be presented in a supplementary table 1.

Radiotherapy includes therapeutic radiation, with or without concurrent chemotherapy; accordingly, only palliative radiotherapy, such as pain control for bone metastases, will not be included in this treatment option. Instead,

palliative radiotherapy without curative treatment will be classified as BSC. Within the radiotherapy category, CRT will include any type of chemotherapeutic agent and any radiation dose and will be pooled and visualised using a mapping tool. Detailed information about CRT will be presented in another online supplementary table.

BSC includes general conservative management and palliative treatments such as surgery for obstruction or bleeding and radiation for pain control. ONT includes any type of novel treatment option not classified in one of the former four categories, as discussed in the Introduction section. As the ONT group will inevitably include highly heterogeneous treatment modalities, we will only use this group to visualise trends and not for quantitative analysis. Detailed information about ONT will also be presented in separate online supplementary table.

In patients with multiple and serial treatment modality, the classification is according to the 'first' treatment option. For example, if one patient received (CRT → chemotherapy → BSC), he or she will be regarded as the CRT group.

Outcome measures

Because this review is basically an EM, the outcome measure is visualisation of mapping itself. However, to structuralise the detailed trends, we will explore treatment trends according to (1) use of treatment, (2) efficacy (overall survival) over time and (3) side effects of treatments.

If there are feasible studies for quantitative analysis, we will conduct the meta-analysis or network meta-analysis. In this case, the primary outcome will include OS. Given the characteristics of RePC, OS should be classified into survival after the first resection and survival after the first detection of recurrence. We will use these two concepts separately. If any study does not distinguish these survival concepts, we will contact the author to validate the survival definition. Regarding EM, the primary outcome is the treatment trend itself, which will be visualised using a graphically mapping tool.

Data search and selection

Data sources

Four electronic databases, Medline, Embase, Cochrane Library and Scopus, will be searched from their inception to March 2017. In addition, cited references from relevant

articles and all abstracts from major international conferences will be manually searched.

Search strategy

The global search strategy is shown in table 3, and the practical search terms will be applied according to the query entry rules for individual databases. If any up-to-date evidence is published during the review period, we will evaluate the eligibility of each study and consider its addition to the suitable group. Web of Science will be used to conduct a manual search for citations of relevant articles.

Inclusion and exclusion criteria

The screening and inclusion process will involve two steps: first, title and abstract; and second, a full-text review. Two independent authors (J-cL and J-HK) will conduct this process. Any discrepancies will be resolved in a consensus meeting with a third author (SA). We will use citation managers such as Endnote to create new folders that meet various conditions.

Assessment of the risk of bias in included studies

The risk of bias will be independently evaluated by two authors (J-cL, J-HK). The result of this assessment will be verified by a third author (SA). For RCTs, the 'risk of bias' tool in the Cochrane Handbook (V.5.1.0) will be used.⁴⁷ For non-randomised studies (NRS) of interventions, we will use risk of bias in non-randomised studies of interventions tool.⁴⁸ For survival rates of single-arm studies, we will use the risk of bias in prevalence studies tool by Hoy *et al.*⁴⁹ For case reports and case series, the National Institutes of Health quality assessment tool will be used.⁵⁰

Evidence mapping and its novel tool, PLOEM

In previous studies, the EM was sometimes, but not always, described as an evidence gap map (EGM).^{41 51–53} This could confuse the researchers and readers. We distinguished the EM from the EGM for the following reasons: (1) the EGM is similar to the alternative of SR and could be used as a bridgehead for subsequent research. The EM, on the other hand, is somewhat complementary to SR. (2) Both EM and EGM can focus on visualisation; however, EM weighs visual graphs, whereas EGM uses

Figure 2 Basic structure of PLOEM V.1.0. PLOEM, Plotting E-Map.

visual tables. In this review, we will adopt EM rather than EGM.

To visualise multiple types of evidence easily and reproducibly, we developed a new mapping tool, PLOEM, using the Javascript language. This web-based, open-access and automatic visualising tool is intended for users performing EM. Unlike several earlier EM methods,^{41 43} PLOEM does not treat evidence gaps. Instead, it focuses on 'automatic mapping' itself when dealing with complex evidence. We have already launched a free website for PLOEM V.1.0 (<http://www.plotting-e-map.com>) and now developing PLOEM V.2.0. The upgrade items are shown in online supplementary table 1.

The basic structure of PLOEM comprises two pages: the input and output pages (figure 2). On the input page, users can insert basic information about eligible studies in a line-by-line manner. Using the data extraction form (DEF) button on this page, users can directly download information entered into a Microsoft Excel file. After completing the input page, users can easily and automatically obtain the visualised results using the Graph button. On the output page, each dot shape depicts the type of study in table 2. The number inside each dot matches the study identification (ID), and when clicked, each dot links to its corresponding study. Using the mouse rollover function, users can easily check the basic information about each dot in a pop-up box. On the output page, users can observe trends in evidence by time, treatment modality and study type.

Data extraction

If eligible studies are found to use specific combinations of treatments, two authors (J-cL, IC) will individually extract the data. The extraction process will be based on the DEF. The data extraction process will be established in consensus meeting (J-cL, IC and SA). We will extract data from each included study as follows:

- (1) Study characteristics: study ID, (2) reviewer name, (3) title, (4) author, (5) published year, (6) nation, (7) hospital level, (8) sample size and (9) study design;
- (1) Demographic characteristics: age (with median and range), (2) sex as percentage of females, (3) recurrence type, (4) recurrence-free period, (5) pathological margin results (such as R0, R1 and R2) and (6) outcomes of each study;
- (1) Check for exclusion: other than the original article, (2) duplication, (3) pathology other than adenocarcinoma, (4) incomplete surgery and (5) not including recurrence.

If the required data are ambiguous or not reported in the clinical articles, the authors will contact the first or corresponding author of the study by telephone or email and collect the missing data using the DEF.

Statistical analysis

All statistical syntheses and analyses will be performed using Review Manager Software V.5.3 (Cochrane Collaboration, <http://tech.cochrane.org/RevMan>). If more than two studies of each type are eligible for analysis, we will combine the studies for a meta-analysis by study type. Different

study designs will be analysed separately. The meta-analysis portion could be limited.

Effect size and pooled estimate (model)

If eligible studies exist, we will synthesise the HRs of OS. If the information from an individual study is insufficient, we will estimate the overall HR using practical methods for incorporating the summary time-to-event data into a meta-analysis of RCTs.⁵⁴ Although this review is conducted carefully, each group should have high heterogeneity inevitably for following reasons. First, the conditions of patients such as age, performance status, comorbidity are various and they influence the treatment modality. Second, even in the same metastatic recurrence group, the diseases burdens are various. We will use the DerSimonian–Laird random-effects model to obtain pooled estimates for RCTs and NRS, given the expected high heterogeneity in each group.⁵⁵

Heterogeneity analysis

Based on the clinical characteristics of RePC and our pilot search, the heterogeneity among studies is expected to be very high. If possible, heterogeneity among studies will be evaluated using I^2 statistics, with 30%, 50% and 75% as the cut-off points for low, moderate and high degrees of heterogeneity, respectively.⁵⁶ We will perform another type of subgroup analysis by specific era, because the treatment paradigm has changed according to several important regimens such as FOLFIRINOX or nab-paclitaxel. The improvement of surgical techniques will also be considered as well as the improvement of chemotherapy.

Publication bias

If MA is possible, we will visualise the publication bias in each group using contour-enhanced funnel plots.⁵⁷ However, because the present study emphasises EM, the publication bias analysis will be optional.

Evaluation of the level of evidence

The level of evidence will be evaluated using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system and the GRADEpro GDT programme (GRADEpro Guideline Development Tool working group, <https://grade.pro.org/>).⁵⁸ These tables will include a summary of the intervention effect and the quality of individual outcomes, using the GRADE approach. The quality of the body of evidence for each outcome will be assessed based on five factors: study limitations, effect consistency, imprecision, indirectness and publication bias.

DISCUSSION

This study will provide two important perspectives: (1) clinical implications and (2) methodological implications.

First, regarding the clinical viewpoint, no consensus has been reached in terms of the management and treatment guidelines for RePC, particularly for surgical intervention. However, in actual practice, our centre often performs ReOPs for solitary metastatic recurrences, and our pilot study of the reports from surgical resection demonstrated

a ‘steady-seller’ pattern. This provided the first motivation for this study.

Second, no standardised tools for EM have been developed, in contrast to RevMan for conventional MAs or WinBUGS for Bayesian MAs.^{32 59 60} Accordingly, researchers conducting EM have been required to draw graphics manually, without assistance from automatic tools. Moreover, no available tools could simultaneously demonstrate time factors, multiple treatments, study types and comparisons. In this context, we established a novel device for EM. We expect some criticism of EM as a mere ‘mapping’ method with no quantitative analysis. However, many issues meet the following parameters: (1) clinical importance, (2) insufficient RCT data, (3) evidence scattered among multiple databases and abstracts and (4) multiple treatment options.

In conclusion, this review will provide new SR-EM-MA of the available treatments and research for RePC, and we expect that our study results will be applied to the updated guidelines for pancreatic cancer. From a methodological viewpoint, this study will serve as a powerful and standardised tool for EM.

Ethics and dissemination

This SR-EM-MA does not require formal ethical approval because the data used in this analysis do not involve personal information and thus do not affect privacy. The findings of this proposed SR-EM-MA will provide a general overview and evidence of management of RePC with respect to OS. The findings will be disseminated through peer-reviewed publications or conference presentations.
