Evaluation of the Choosing Wisely Australia 5 Questions resource and a shared decision-making preparation video: protocol for an online experiment

Danielle Marie Muscat,1 Edward Hoi-fan Chang,2 Rachel Thompson,1 Erin Cvejic,1 Marguerite Tracy,2 Joshua Zadro,3 Jessica Kathleen Smith,2 Robyn Lindner,4 Kirsten McCaffery1

ABSTRACT

Introduction Choosing Wisely, an international effort to reduce low value care worldwide, considers communication between clinicians and patients during routine clinical encounters a key mechanism for change. In Australia, Choosing Wisely has developed a 5 Questions resource to facilitate better conversations. The primary aim of this study is to evaluate the impact of the Choosing Wisely Australia 5 Questions resource and a video designed to prepare patients for question-asking and participation in shared decision-making on (a) self-efficacy to ask questions and participate in shared decision-making, (b) intention to participate in shared decision-making and (c) a range of secondary outcomes. The secondary aim of this study is to determine whether participants’ health literacy modifies the effects of the interventions.

Methods and analysis We will use 2×2×2 between-subjects factorial design (preparation video: yes, no × Choosing Wisely 5 Questions resource: yes, no × health literacy: adequate, inadequate). Participants will be recruited by an online market research company, presented with a hypothetical non-pain scenario, and randomised to study groups stratified by health literacy. Quantitative primary and secondary outcome data will be analysed as intention-to-treat using appropriate regression models (ie, linear regression for continuous outcomes, logistic regression for dichotomous categorical outcomes).

Ethics and dissemination Ethical approval for this study was obtained from the University of Sydney Human Research Ethics Committee (protocol number: 2018/965). The results from this work will be disseminated through peer-reviewed international journals, conferences and updates with collaborating public health bodies. Resources developed for this study will be made available to patients and clinicians following trial completion.

Trial registration number This trial has been registered with the Australia New Zealand Clinical Trials Registry (trial number: 376477) and the stage is Pre-results.

Unnecessary and potentially harmful services account for a significant proportion of total health expenditure.1 The need to eliminate unnecessary medical care, decrease waste and reduce overdiagnosis has received increasing attention from health systems in the past decade. One initiative that has gained momentum worldwide is Choosing Wisely.2 Launched in April 2012 by the American Board of Internal Medicine (ABIM) Foundation, the Choosing Wisely campaign has now been adapted and implemented in more than 20 countries worldwide. The campaign seeks to encourage clinicians and patients to talk about medical tests and procedures that may be unnecessary, and in some instances,
Box 1 The choosing Wisely Australia 5 questions

- Do I really need this test, treatment or procedure?*
- What are the risks?
- Are there simpler, safer options?
- What happens if I don’t do anything?
- What are the costs?†

* Original Consumer Reports question: Do I really need this test or procedure?
† Original Consumer Reports question: How much does it cost?

The 5 Questions Resource has been promoted for reducing the use of unnecessary tests and treatments, leaders of the campaign consider communication between clinicians and patients during routine clinical encounters a key mechanism for change.

As part of the original Choosing Wisely campaign, Consumer Reports (an independent non-profit product-testing organisation) partnered with the ABIM Foundation and developed five questions for patients to ask healthcare providers to support better conversations about unnecessary tests, medications and procedures. The questions are publicly available and have been promoted for use nationally and internationally. The five questions were adopted by Choosing Wisely Australia (with some minor phrasing changes; see box 1) and have been disseminated in several forms and languages, including as a one-page downloadable resource, ‘5 Questions to Ask Your Doctor’ (hereafter referred to as the 5 Questions Resource), that lists the questions and provides additional guidance in their rationale and use (see online supplementary appendix A). Annual evaluation surveys conducted by Choosing Wisely Australia suggested that, in 2015 and 2016, 8% of healthcare consumers were aware of the 5 Questions Resource and, in 2017, it was the organisation’s most commonly downloaded material (4).

The 5 Questions Resource has been promoted for its ‘potential to facilitate better conversations between healthcare providers and consumers’. However, it has yet to be formally evaluated, and the precise expected mechanism of action for its effect on the use of low value care has not been investigated. Notwithstanding, question prompt lists of this kind are typically regarded as a strategy for facilitating shared decision-making and thus, improved shared decision-making is an obvious potential mediator of the hypothesised effect of the 5 Questions resource on the use of care.

Despite its potential, focus testing by Choosing Wisely Australia suggested that the 5 Questions Resource alone may not be sufficient for enabling patient question-asking as people may continue to feel that they do not have permission to ask questions. In response to this, Choosing Wisely Australia has developed accompanying resources (eg, posters featuring local hospital staff, a video illustrating how to have conversations with health professionals) that address some potential barriers to the impact of the 5 Questions Resource (eg, the social unacceptability of active participation, patient concerns about healthcare providers’ reactions and possible retribution). However, other elements proposed as critical for preparing patients in advance of exposure to a shared decision-making intervention (eg, explaining that there are two experts in the encounter (healthcare provider and patient), challenging attitudes that there are universally right and wrong decisions) remain unaddressed by these resources. An intervention that addresses all elements considered critical for patient preparation may enhance the impact of the 5 Questions resource and may also, on its own, be beneficial.

The impact of the 5 Questions resource may also depend on patients’ health literacy, which is ‘the cognitive and social skills which determine the motivation and ability of individuals to gain access to, understand and use information in ways which promote and maintain good health’. Adults with lower health literacy have worse health outcomes (eg, increased hospital admissions and readmissions, poorer chronic disease outcomes and increased mortality), and importantly ask fewer questions when seeing healthcare providers.

Previous research shows that interventions that are tailored to an individuals’ health literacy level can support more effective communication and potentially reduce health inequalities for people with lower health literacy. However, intervention developers often fail to tailor the design of their interventions to adults with lower health literacy and rarely evaluate their impact in this group.

OBJECTIVES

Our overall objective of this study is to better understand the potential of the Choosing Wisely Australia 5 Questions Resource and a newly developed shared decision-making preparation video for facilitating shared decision-making and reducing the use of unnecessary tests, medications and procedures. As this study represents the world’s first evaluation of both interventions, we intend to deliver them online to a community sample using hypothetical vignettes. Participants are asked to imagine being in a specific clinical scenario and proximal cognitive-affective outcomes are assessed following randomisation to different interventions. We consider demonstrating evidence of impact in cognitive and affective outcomes an important first step before embarking on evaluation in the healthcare setting. Our primary aim is to assess the impact of the interventions on participants’ (a) self-efficacy to ask questions and participate in shared decision-making, (b) intention to participate in shared decision-making and (c) a range of secondary outcomes. Our secondary aim is to determine whether health literacy modifies the impact of the interventions.
METHODS

The study methods have been informed by an unpublished pilot study of the intervention (n=164), which included a qualitative interview study with a subset of health consumers (n=25) to refine the interventions and outcome measures. Data collection is planned to start in November 2019 and finish in December 2019.

Study design and setting

We will use 2×2×2 between-subjects factorial design (preparation video: yes, no × Choosing Wisely 5 Questions Resource: yes, no × health literacy: adequate, inadequate). This design will enable us to assess the relative impact of different interventions, both alone and in combination compared with no intervention. This design will also allow us to explore whether health literacy modifies the impact of these interventions.

This study will be conducted online using the Qualtrics survey platform. Randomisation will be undertaken via an automated function in the survey platform using an equal allocation ratio and stratification by participant health literacy (adequate, inadequate), yielding four trial arms in each health literacy subgroup: (a) preparation video alone, (b) 5 Questions Resource alone, (c) preparation video and 5 Questions Resource and (d) no intervention. Participants will not be blinded to their assigned intervention.

Participants, recruitment and consent

To be eligible to take part, potential participants must be aged 18 years or older; be an Australian citizen or permanent resident and possess sufficient self-assessed English language skills to complete questionnaires in English.

Participants will be identified, pre-screened for eligibility and invited to consider participation by Dynata, a market research company with a database of 600,000 people willing to be involved in online research. Dynata uses a points system whereby points are earned for completion of surveys which can be redeemed for items such as gift vouchers, donations to charities or cash. If participants agree and are interested in being part of the study, they will be directed to an online survey hosted in Qualtrics. The first page of the survey will display the downloadable Participant Information Statement (see online supplementary appendix B). In line with the Australian National Statement on Ethical Conduct in Human Research, 2007 (updated 2018), we have received ethical approval to regard completion of the questionnaire as an indication of consent. Participants are also required to select ‘Yes, I would like to participate’ to enter the survey.

During the study, all participants will be presented with a hypothetical healthcare scenario that asks them to imagine being in a situation where they have non-specific low back pain and stable pain/symptoms (see box 2). Non-specific low back pain describes pain between the inferior border of the twelfth rib and lower gluteal folds that is not caused by a serious or specific underlying pathology." Back pain was the eighth most frequently managed problem Australian general practice in 2015 and non-specific low back pain accounts for approximately 90% of low back pain cases. Routine imaging for non-specific low back pain has been shown to have more harms than benefits, and furthermore many medical treatments provide little-to-no benefit over placebo.

Interventions

Preparation video

We developed a short video (3 min) intended to prepare patients for question-asking and shared decision-making. Our rationale for this choice of intervention included that multimedia formats can be a successful tool in engaging and educating patients with low health literacy and encouraging or modifying patient behaviour and that videos featuring real people have been found to be more effective than those which only provide graphically presented information with voice overs. The video script (online supplementary appendix C) was developed through an iterative process and was intended to integrate the recommendations for effective preparation as outlined by Joseph-Williams and colleagues. The transcript was developed with reference to the Listenability Style Guide which outlines principles to make spoken discourse more comprehensible and ease the cognitive burden of listening (eg, repetition of ideas; simple and common idioms; vivid analogies; use of questions to focus the listener’s attention). The readability level of the script was also checked and adjusted until a grade five readability level was achieved.

Choosing Wisely Australia 5 Questions Resource

The Choosing Wisely Australia 5 Questions Resource is a one-page document co-branded by Choosing Wisely Australia and NPS Medicinewise that lists the Choosing Wisely Australia 5 Questions (see box 1) and provides additional guidance in their rationale and use (see online supplementary appendix A). This resource has a readability score of 9.4.

Implementation of interventions

The interventions will be displayed to participants within the survey platform. To ensure intervention exposure, a timer has been added to the pages displaying the video (3 min) and 5 Questions Resource (1 min), preventing participants from progressing to the next survey page until the specified time has elapsed. In the preparation
Figure 1 Time schedule of enrolment, interventions and assessments.

- Video and 5 Questions Resource arm, the video will be presented before the 5 Questions resource. Participants will not be prevented from exposure to any other care or interventions prior to or during the study.

**Data collection**

Study data will be collected via surveys administered immediately before (‘Pre’), immediately after (‘Post’) and 2 weeks after (‘Follow-up’) exposure to the relevant intervention(s) (see figure 1). All outcomes will be assessed by participant self-report with the exception of ‘Indicator of proactive intervention use’ (see Outcomes and Measures).

**Outcomes and measures**

Primary and secondary outcomes for the study, as well as measurement instruments and analysis metrics, are shown in table 1. Outcomes and measures were refined following a pilot study (n=164). Unpublished pilot data are available from the authors on request.

**Demographic and health data collection**

In addition to the primary and secondary outcomes, participants will be asked to report their age, gender, Australian state of residence, language spoken at home, education status, employment status, private health insurance status and confidence in filling out medical forms. Participants will also be asked to indicate who is usually involved in healthcare decision-making related to their health, and about their experience and perceived knowledge of low back pain. Health literacy will be assessed by the Newest Vital Sign (NVS), with participants categorised as inadequate (score 0–3 on NVS) or adequate literacy (score 4–6 on NVS). The NVS has been used in other online studies, and is an objective, performance-based measure of health literacy skills. We will also administer a single-item measure of self-reported health literacy for the purposes of describing the sample.

**Analysis**

**Quantitative data analysis**

The study statistician will be blinded to the intervention allocation of participants and their level of health literacy until after completion of analyses; a research assistant who has no other involvement in the trial will remove all group identifiers prior to analysis. Quantitative primary and secondary outcome data will be analysed as intention-to-treat using appropriate regression models (ie, linear regression for continuous outcomes, logistic regression for dichotomous categorical outcomes). Dichotomous variables representing the study factors (preparation video: provided, not provided; Choosing Wisely Australia 5 Questions resource: provided, not provided; health literacy: adequate, inadequate) and their interactions will be included in models as between-subjects fixed effects, controlling for pre-intervention values (where available). Outcome data collected during the immediate post- and follow-up survey will be analysed in separate models. Any significant interactions will be follow-up by subgroup analyses based on potentially relevant demographic variables.

**Missing data**

The use of an online survey platform minimises the risk of missing data; participants are required to provide responses to each question before moving on to subsequent items. As such, data are only missing in cases where participants discontinue prior to providing responses for outcome measures. Participants who discontinue the study before completion of the (immediate) post-intervention survey will be excluded from all analyses. Multiple imputation will be used to impute occasional cases of missing data (eg, some outcome measures incomplete) or for missing responses for participants who complete the initial (pre- and post-) surveys, but do not return to complete the 2-week follow-up survey. If multiple imputation of missing data is utilised, sensitivity analyses will be performed comparing the outcome from complete case with imputed analyses.

**Sample size**

Sample size estimates were derived based on the primary outcome of intention score, with the estimates of effect based on previously published values and refined considering pilot data. For each stratified analysis arm (ie, inadequate health literacy, adequate health literacy), a sample of n=162 subjects per intervention group is expected to provide approximately 80% power to detect a small main effect (effect size of 0.10 or greater) of the...

</table>
Choosing Wisely Australia 5 Questions resource; and over 80% power to detect small main effects (effect sizes 0.20 or larger) of the preparation video intervention, and their interaction, at a p-value of 0.05 in primary analyses. As such, we aim to recruit a total sample size of n=1432 (ie, 716 with inadequate health literacy and 716 with adequate health literacy; with n=179 participants randomly allocated to each intervention group [preparation video alone, Choosing Wisely Australia 5 Questions resource alone, both Choosing Wisely questions and preparation intervention, and control]). This will allow for a drop-out of approximately 10% of participants who discontinue the study before completing the (immediate) post-intervention survey measures.

**Qualitative data analysis**

Assessment of healthcare questions deemed by participants as important to ask in their hypothetical scenario will be analysed via content analysis. Coding will first be done deductively based on concepts embodied in the Choosing Wisely Australia 5 questions. Two double-blind coders will review all data and code any questions that fit broadly into 1 of 5 categories: Do I really need this test, treatment or procedure? What are the risks? Are there simpler, safer options? What happens if I don’t do anything? What are the costs? Any discrepancies will be resolved through discussion between coders. Remaining responses will be coded inductively with categories derived from the data. Inductive codes will be collected to form coding sheets and categories freely generated and grouped through the abstraction process. The coding scheme will be revised over an iterative process of discussion and revision to ensure all themes are captured. Based on our previous work, data will be presented in the form of frequencies expressed as percentages and actual numbers of key categories. We will also report category names, definitions and data examples.

**Data storage and management**

After enrolment, a unique identifier will be assigned to each study participant. Any participant identifiers will be removed before the data are archived for storage. Data will be downloaded as spreadsheets and stored on password protected computers which are encrypted per university policy. Listed investigators will have access to the final study data set.

**Patient involvement**

A consumer was involved in the study design. The consumer helped select outcomes and outcome measures, develop and refine the intervention, and will inform the interpretation of the analysis and dissemination of findings. Our study protocol was also presented to a Choosing Wisely Australia Board Meeting, with specific feedback sought from the two consumer board members.

**Funding**

The study was funded by a National Health and Medical Research Council (NHMRC; help@nhmrc.gov.au) Program Grant (APP1113592). NPS MedicineWise gave permission for investigators’ use of the Question Prompt List leaflet without charge. EC was supported by a Sydney Medical School Summer Research Scholarship and KM was supported by an NHMRC Principal Research Fellowship (1121110). Neither the NHMRC nor Sydney Medical School had any role in the design of this study. They will not have a future role in the conduct or write-up of the study or in the decision to submit the findings for publication. A representative of Choosing Wisely Australia (RL) contributed to the design of this study and will have a future role in the conduct and write-up of the study. NPS MedicineWise will not have a role in the decision to submit the study findings for publication.
